(Special Correspondence).—The lode extending from the vicinity of Julian to Banner and beyond, in the Cuyamaca range, is experiencing one of its periodical revivals. The district was discovered by M. Julian, and he, with a number of others, formed the original district. Among the noted mines of the early days in the district were the Washington, Owens and High Peak, in the vicinity of Julian; the Helvetia, Antelope, Kentuck S. and Cincinnati Belle, between Julian and Banner, the Ready Relief at Banner and the Golden Chariot, several miles from Banner. These mines, and others of the district, have been worked in a spasmodic manner, usually by men of limited means, but they have produced many thousands of dollars. The ore is above the average in grade, and the district on the whole justifies more systematic exploration than it has ever received. At present there is one of the periodical revivals in progress. The Helvetia mine, after an idleness of several years, is again active, and it is reported in bonanza. The High Peak mine, near Julian, is again being worked and a good showing made. A stamp mill, built originally for the Cincinnati Belle, near Julian, has been removed to the High Peak. Other machinery has been placed on the mine recently. It is the intention of this company to sink a deep shaft and systematically prospect their ground. The principal drawback of the district is the lack of water, though sufficient for steam and small milling operations is obtainable. Another disadvantage lies in the fact that the ore occurs in mica schist in a series of lenses and the shoots do not occupy continuous fissures. Consequently, when a lens of rich ore is worked out, prospecting must be done to find another, and it has too often been the case that the prospecting has been deferred until there was no ore left in sight, when the mine would be abandoned until the next fellow with cash and courage would search for and find another

shoot. The mines, generally speaking, have too little ore to justify an independent mill. If several mines of the district would unite to build a joint company mill, the several mines might be able to keep the mill in continuous operation.

Julian, Feb. 25.

#### Sierra County.

(Special Correspondence).—The Empire mine, near Downieville, is now running under the superintendence of T. K. Code, E. M., who in the past three months, since taking charge of the mine, has hocked out 12,000 tons of ore, which sampled over \$7 per ton. The vein is 5½ feet wide. The 20-stamp mill is running full time and the mine is on a paying basis. Within the past three years the mine has had four superintendents, but none of them before now ever run the mill. There are other mines in this county, which, with proper management, could be placed on a paying basis in a short time, but which are now idle.

Downieville, Feb. 23.

It is reported that the Mountain mine near Sierra City will be started up by Superintendent L. H. Carver. New buildings will be put up to replace those destroyed by fire last December. He will put in a new rock breaker and an electric dynamo for power and lights.

A rich strike is reported at the Mountain mine, near Sierra Buttes. A discovery of a vein a few inches wide was made on the surface, and Superintendent Carver made a survey and directed a raise to be driven from tunnel No. 2, which cut the vein 50 feet above the level. The ore runs over \$60 per ton and is now 2 to 5 feet wide. A new tramway is to be built and other improvements made to replace those burned last fall. At the time of the fire the mill had just begun to run.

#### Siakiyou County.

C. R. Richardson has finished cyaniding the tailings of the Black Bear mine. In the past eighteen months he has cyanided 10,000 tons, from which \$15,000 was realized. He is now operating his plant on Black Bear creek with good profit.

The hydraulic mines owned by Gardner & Eastlick and Wright & Fletcher at Oro Fino are running with giants and elevators. Both companies have opened new ground for the season. The water season has been rather short, but from now on no trouble will be had.

Many acres were recently bonded around Oro Fino, which is being prospected by drill machine. It is a question as to the depth of the ground to be handled that may interfere with the scheme around Oro Fino and up to the Pinery placer claims on Kilder creek. The hydraulic lands in that neighborhood returned from \$10,000 to \$17,000 per acre.

The Gold Dyke mine is being developed by L. Monahan, and good ore is being crushed in the new 3-foot Huntington. It is averaging twenty tons of ore daily. The ledge is a large porphyry dyke, and the present plant was put on to prospect the property. It is the intention to put on a larger plant if the mine proves a success with development.

The placer mines about Happy Camp are reported working with plenty of water.—J. L. Mahan will let a contract to continue work in the upper tunnel of his property, 2½ miles southwest of Happy Camp, and will resume development in the lower tunnel. The ledge makes a good showing of ore of fair average values. A mill test of several tons of ore taken between walls some time since, without sorting, netted \$21 per ton.

#### Tuolumne County.

At the Los Angeles mines, on Tuolumne river, above Ward's Ferry, near Sonora, twelve men are employed and more will be put on. The mill is running steadily on good ore. Superintendent Kuhns says an addition of five stamps will be made to the mill, making fifteen stamps in all.

Men have been placed on the Nonpareil, near Big Oak Flat, on development.

At the Neversweat, near Big Oak Flat, there has been extracted considerable ore of high grade, which is to be taken to a custom mill.

Fifteen men are working at the Clio, near Jacksonville. The company intends to thoroughly test this mine.

The shaft in the Longfellow mine, at Big Oak Flat, has passed the 600-foot station and will be sunk deeper. Dividend-paying rock is being extracted and the quartz in sight is sufficient to feed the mill for many months.

The mill at the Experimental has started up and is in full operation. John Conlin is superintendent.

J. Gillis has taken from Jackass Hill a bar of gold worth \$235, from the Carrington claim.

It is reported that a shoot of rich ore has been cut on the 300 level in the Jumper, near Stent.

The Mount Lilly is in full operation. A change room with bathing facilities has been provided for the men. New shoes, dies and plates have been taken in for the mill and stamps will be dropping in a few days. A large quantity of rich ore is in sight and it has been demonstrated that the veins are larger and richer than they were at any place before.

The Draper mine, near Soulsbyville, is being successfully operated. Eight power drills are kept in operation day and night and forty men are employed. A larger hoist will be installed.

At Tuttle town work of unwatering the Bell mine is suspended.

### COLORADO.

#### Boulder County.

At Nederland, Superintendent Loach, of the Wolf Tongue M. Co., is producing tungsten ore. The four mines employ twenty-five men and concentrate the output in a 20-stamp mill, treating 20 tons a day, producing 2500 pounds concentrates. The mill also treats custom ore, charging \$4 per ton and paying for the concentrates at the rate of \$6 per unit. Concentrates that run 60% tungsten bring \$360 per ton; if the concentrates run 50%, \$300. Another mill in the district, at the Boulder County mine, under management of C. W. Lake, treats 20 tons a day from their own mines. Another tract is being operated by E. A. Nereshimer, the ore being supplied to the Boyd mill at Boulder, which has been recently overhauled and refitted for the purpose, and is treating 20 tons per day.

#### Clear Creek County.

The Helen tunnel in Virginia canyon, near Idaho Springs, is being driven on the vein. It was the intention of the management to unwater the old shaft after straightening up the old tunnel, but the showing of ore changed the plan for the time being, for as long as there is a good showing in the face of the drift it will be continued. All the ore taken out in driving the adit is being piled up at the tunnel mouth and stopping ground is being opened. The winze, or continuation of the shaft, which is cut by the tunnel at a depth of 75 feet, is in readiness for the hoisting plant, and it will be put in place after the face of the drift has been driven far enough to prevent injury from blasting.

Superintendent S. Griswold is working on the Lucy claim and the shaft is showing up well. The ore streak found at grass roots continues in the shaft at depth of 30 feet. There is a good streak of milling ore which would yield a profit if there were no smelting ore in the vein. An 18-inch streak of good ore has been cut in the Teller mine 800 feet from the portal.

The Stephens Co. leases on the Mendota mine have twenty-three men at work, producing an average of \$3000 a month for three years. The first-class ore runs \$45 per ton in lead, silver and gold, and is shipped to the Georgetown sampler. The mill turns out a zinc product averaging \$23 per ton, twenty-seven tons of concentrates being shipped each week to Denver. Besides running their own ore the company usually runs about 100 tons of ore for other operators. They have on one of the levels in the Mendota mine a vein of ore 22 inches in thickness and 125 feet in length. L. Stevens is manager of the Mendota mill. In saving zinc the concentrates do not run below 45%.

#### Denver County.

(Special Correspondence).—The Globe plant of the American Smelting & Refining Co. is fighting a \$100,000 damage suit in the district court. The suit is brought by a ranchman living in the vicinity of the smelter to recover damages for losses to stock and crop sustained by alleged reason of the fumes and smoke settling on his property and causing a number of the cattle on the ranch to die from the effects of eating poisoned grass. The smelter and ranch are located about 5 miles from the city.

A bill against "boycotts" and "black lists" is taking the attention of the fifteenth general assembly. Some opposition is being brought to bear against the bill on the ground that it is one-sided and will be a benefit to the employer only.

The reports the past few days are to the effect that the deep drainage tunnel of Cripple Creek district has been temporarily held up on account of lack of support. The chairman of the drainage tunnel association has been absent from the State for some time which accounts for work being suspended for a time. It is understood from one of the interested parties in the project that definite plans will be settled some time this week. It is believed from information received at this time that the tunnel is an assured fact and that all the money necessary to complete the enterprise will be forthcoming. Practically all of the opposition to the tunnel has been removed and it is now a question of raising the required amount to put it through.

Experiments are being made with vitrified brick as a lining for tube mills used in grinding ore in concentrating mills and are said to be proving satisfactory. Efforts are also being made to locate suitable material in this State for use in the mills in case brick will not answer the requirements. Most of the pebbles used come from Iceland and it is believed with the vast resources in the State that a satisfactory variety of flint can be secured here without having to send so far for the material.

It has been announced here that plans are perfected for a new \$50,000,000 smelting and mining combine to be controlled by the American S. & R. Co. The nucleus of the new company is stated to be the Guggenheim Exploration Co., which has \$13,000,000 issued stock selling for \$165 per share. Four large independent smelters will also be absorbed. The company will have \$25,000,000 common stock and \$25,000,000 preferred. The American S. & R. Co. will acquire control of 51% of the stock of the new company for the consideration of a guarantee on a small portion of the preferred stock, which charge will not exceed \$300,000 per annum. No new securities of the American Smelting & Refining Co. will be issued.

Denver, Feb. 28.

#### Fremont County.

The output of the Florence oil field for 1904 was 265,000 barrels. A number of wells have been capped, and the probability is that the output for 1905 will be below that of 1904.

#### Gila County.

Returns from a shipment made last week by A. Kaneppely, working in the 420 west level of the East Notaway mine, returned 22.07 ounces gold, 4.45 ounces silver to the ton, this being among the best shipments of high-grade ores made from this property for some time. L. Mills and F. Crispin, working a block of ground in the west 555-foot level, have opened up fine ores in sinking a winze and the streak carries values of from 15 to 20 ounces gold per ton. J. Hopkins, working in the 555-foot level above where the winze is being sunk, is taking out ore, and McCullough & Hardy will also make a shipment of high-grade ore. Sinking under contract in the shaft is fast nearing the 700-foot point. They have had a large crevice in the shaft, and it is believed when the levels are run in the bottom that good ore bodies will be found. The property is being operated by the Town Topics G. M. Co., and has paid \$50,000 in dividends within the past four years.

Missouri capital is interested in the Missouri & Colorado M. & M. Co., operating the Snowdon property near the head of Silver creek. Sinking has been suspended for the present and drifting is under way. In the drift the vein matter is from 3 to 3½ feet in width, with 7 to 8 inches of smelting ore, carrying average values by shipments of three ounces gold per ton, the balance being a concentrating proposition, with values from \$10 to \$12 per ton. W. C. Hollister is manager.

There are twenty men employed at the Mackey mine

by the Imperial G. M. & M. Co., under the management of L. J. Mountz. Regular shipments of two or three cars are being made weekly to Argo, these ores averaging \$20 to the ton. Another carload shipment of high-grade ores will be made to the smelter, the last car of high-grade ore returning \$207. The high-grade ore is being taken out from the east 150-foot level, and in sinking a winze at that point Manager Mountz reports they have a streak of high-grade ore coming in from the foot wall side.

#### Hiosdale County.

Miller & Co. of New York will develop the Black Swan mine, north of Sherman and east of Argentum.

#### Lake County.

(Special Correspondence).—There were shipped from the mines of the Leadville district during February 73,000 tons of ore, a slight increase over the January tonnage. The bulk of this ore was low grade. There has been some increase in the shipments of high-grade carbonates from the downtown district and from Rock hill. The principal shippers and their average tonnage are the Iron Silver M. Co., 12,000 from the Moyer; Western M. Co., 250 tons per day from the Coronado and Midas, and about 300 per day from the A. Y. & Minnie, Adams and other properties; Yak M., M. & T. Co., 8000 tons from the Silver Cord, Tankerstown and Bob Ingersoll; Reindeer, 3500 tons; Ollie Reed, 4500 tons; Small Hopes M. Co. and lessees, 3000 tons; Ihex and lessees, 6000 tons; Penn properties, operated by lessees, 3000 tons; Fryer Hill M. Co., 4500 tons. The balance of the tonnage comes from small properties operated principally by lessees.

The Iron Silver M. Co., operating the Moyer, North Moyer, Tucson and Dome, has declared a dividend of \$50,000, payable March 4. Last year this company paid \$350,000 in dividends, although the average value of the 150,000 tons of ore mined was less than \$10 a ton, and \$150,000 was expended upon development and surface improvement.

Development of the new territory recently opened up on Rock hill is being retarded by unexpected flows of water. Nearly all of this territory has been drained to a depth of 400 or 500 feet by the Coronado and Penrose pumps, and the shafts on the higher portions of the hill are dry to that depth. The Nil Desperandum, which is being sunk by the Rock Hill M. Co., struck a flow of water at a little less than 700 feet. The United No. 1, which is being sunk by the United M. & D. Co. of A. on the George H., has also encountered a steady water course, and other properties in that vicinity have cut into small streams. While these courses are not large when compared with those from which the downtown pumps are lifting 700 to 800 gallons per minute, they are heavy enough to interfere with operations and create a demand for pumping machinery.

The Empire Tunnel Co. of Georgetown is operating the old Cloud City shaft in the downtown district. The Cloud City and the Home Extension properties, which this company has secured, lie to the west of the Western M. Co.'s downtown mines, adjoining the Coronado, Midas and Penrose. The Empire Co. is spending \$150,000 in sinking the Cloud City shaft to the second contact to open up the extension of the Coronado shoots. The shaft is now down 630 feet and will go 75 feet deeper. A station is being made at the 630-foot level and a 500-gallon pump will be installed at that point. The mine is now being drained by a 300-gallon pump, but, being much lower than the Penrose, the company is preparing for possible danger from an increased flow. In the old upper levels of this mine low-grade ores have been taken out, a particularly fine body of manganese having been worked last year. W. S. Jones is superintendent, F. A. Maxwell of Georgetown general manager, Clarence Jarbeau of Georgetown secretary. The plans of the company, as announced when it took charge of the Cloud City, include the building of an independent smelting plant to treat the ores from its properties in Clear Creek county and from the Cloud City, the Leadville ores being desired for their fluxing qualities.

The development of the new Rock hill section is progressing, and March is expected to see the surface plants and machinery installed for the sinking of new shafts on the Parson claim by F. H. Minard and his New York associates; on the Rock Hill Con. group by F. Bulkley of Denver, and on the Revenue ground by T. F. Daly of Denver.

Leadville, Feb. 28.

#### Ouray County.

The Ben Hur group in Sneffels mining district has been sold to a company of St. Louis capitalists. The property consists of eight claims, located between the Camp Bird and the Revenue mines. While very little work has been done on it, it is considered valuable because of certain known veins intersecting it.

#### Sao Juan County.

The Creole Belle group of claims passes to the Ross M. Co. This group, consisting of the Creole Belle, Grand Duke and Oracle claims, is near the Sunnyside mine, near Eureka, 10 miles up the Animas river from Silverton. The claims were located twenty-five years ago. The property has considerable development and the richness of the mineral zones has been established, although the work up to this time has been confined chiefly to surface workings. A year ago sixteen carloads of ore from the group was shipped to the smelter, and returns averaged over \$60 to the ton, mostly in gold. The Ross M. Co. is a new organization and has been operating in this county for a year or so, but in that time they have become the owners of some valuable mining ground. Among them is the Galty Boy group, up Cement creek. Development work on the Creole Belle group will be continued. It is expected a mill will be erected this summer.

#### Summit County.

There is talk of several dredgers being put up on the Blue on the Lamhing ground, now owned by the Blue River Excavating Co. There is also report of one or more dredgers being built on this property and one or more on the ground controlled by the company at Dickey.

The Gold Pan Co. is doing all possible to get an early start. The drainage flume run by the Mekka Co. will

be completed to the pit started by Mr. Kingsbury. During the continuance of the work on the flume, which will not rest on bedrock until it reaches the pit, a hydraulic lift will be used to test and clean the bedrock along the course of the flume, using it to carry off the gravel.

Never before have the prospects for placer mining looked as encouraging as now. The heavy falls of snow so far this winter are already sufficient to guarantee plenty of water with which to carry on operations during the summer, and some companies are already making preparations to resume. Work will be started as soon as conditions permit. On the Blue, Swan and French rivers placer operations will be pushed.

At Breckenridge the Germania G. M. Co. is incorporated by T. R. Keith and H. S. Bonchhoff of Breckenridge and W. O. Pratt of New York. Main office is in Breckenridge; main workings, Georgetown district. J. G. Goodier of this place, W. C. Off and C. A. Kellogg of Breckenridge, have incorporated the Abundanco M. & M. Co. They will develop properties near the Old Union, Oro and Wellington on Mineral hill.

#### Teller County.

A new body of ore has been encountered on the Anaconda property. The shoot was cut 6 feet below what is known as the Howard flat vein, which belongs to the Mary McKinney Co., and like the McKinney vein is flat. The find was made by Anderson and associates, who have been working on the McKinney ground, and believing that the vein was going into Anaconda territory the manager of the Anaconda Co. offered them a liberal lease on that section of ground, which is known to the Anaconda estate as block 46. The lessees, going to work through the Anaconda main tunnel level, soon opened up the body of ore. Their assays indicate that the ore will run better than three ounces to the ton. What is known as the Howard vein has been worked at different points and has always proved a success. These operators have opened up a large body of ore where it is believed the values of the Howard vein have shifted to a lower vein.

High-grade ore has been found at 1100 feet in the American Eagle's shaft of the Stratton's Cripple Creek M. & D. Co. on Bull hill. The find was first opened on the Shurtloff claim, 50 feet west of the main vein of the Findley Con. Co. The ore streak is from 12 to 15 inches in width. The new vein is believed to be the old Garfield Grouse vein that in the early days proved a good producer.

It is calculated by Mason & Murphy, lessees of the Monte Cristo, on the northwest slope of Beacon hill, that they will need to sink 160 feet before the extension of the rich shoot, opened in the El Paso near by, is encountered. A depth of something over 100 feet has to be attained. Another lift will probably have to follow to provide stopping ground. Work is being energetically prosecuted.

Operations have been resumed on the Fountain Valley claim of the Banner G. M. Co., under lease to Crowder, Wilder & Co. Suspension was necessitated by water.

In the proposed new drainage tunnel, Cripple Creek mine owners favor driving it, as outlined in plan No. 2. The committee in charge propose to raise funds to push it several hundred feet farther to the east than was originally planned, so that the mines near the Victorator may benefit therefrom. It is figured that a tunnel, driven 750 feet below the level of the present one, would add ten years to the life of the Cripple Creek mines.

Many Cripple Creek miners are going to South Africa with F. Renfrow, a representative of a number of South African mining companies. Each man has signed a contract for three years. They are to receive \$5 per day; board \$4.50 a week.

The Solar M. Co. has a bond and lease on the Ollie Placer and Last Chance lodes on Mineral Hill and has opened a body of ore. The lease runs eighteen months. The operators have been interested in Mineral hill for a number of years, always believing that it would yet give up a producer. They opened the present body of ore at a depth of 30 feet from surface, where the vein has been proved up for a width of 15 feet, returning average values of \$10 to the ton for the entire body of ore. The lessees believe they have found the source of the placer gold that has from time to time been panned in this neighborhood. A plant of machinery has been ordered and they expect to commence building a large shaft house. This find, together with that recently made on Copper mountain on the Buckeye, means much to Cripple Creek, as this territory is located contiguous to the city.

S. S. Bernard, president of the El Paso Con. G. M. Co., denies that negotiations are pending with English capitalists for a controlling interest in the company. The El Paso company was incorporated in 1894. The gross production of the property up to the first of this year was \$3,036,311. The gross production during the last six months of 1904 was \$752,235, and the net production \$661,308. Construction of an addition to the El Paso ore house is nearing completion. The new part is nearly ready for use. It is calculated by Superintendent Bainbridge that the addition will increase the facilities in this department by 50%.

### IDAHO.

#### Boise County.

Judge Stevens of the district court signed an order directing Receivers C. N. Clark and W. Mathews to sell at public auction all the properties, including waterworks, electric railroad, smelter and mining property, of the Great White Knob Copper Co. of Mackay, Idaho. The value of the property is estimated at \$2,800,000. There is a mortgage upon the property of \$1,000,000, and the court directs that the minimum bid holds the \$1,000,000 lien, but the court directs that all creditors shall be paid out of the proceeds of the sale. About \$50,000 of the claims are held in Salt Lake City. Other creditors are Denver and Butte firms, whose claims aggregate \$70,000. The receivers have set the sale for March 18th, at Mackay, Idaho.

#### Idaho County.

The Hewey Kearns property on Rapid river, in the Seven Devils, has been bonded to Ohio men for \$40,000.

The new owners will drive a crosscut tunnel to open the vein at depth.

#### Owyhee County.

Near Silver City the Sinker tunnel, in charge of Manager Wilson, employs thirty-five men. The management have installed water jacket drills.

In the Commoner mine, J. H. McGowan manager, the pay streak averages 16 inches wide. The ore, without culling, runs \$230.

In the property owned by the Golden Opportunity M. Co. work has been temporarily suspended. The president is F. D. Kendrick of St. Paul, Minn. Work will be resumed about May 1.

#### Shoshone County.

Regarding the strike on the Snowshoe, one of the copper properties of Mullan, the Press hears that 2 feet of ore carries 11% copper. This, with the silver values it carries, brings it up to \$40 per ton.

Near Thiard the Wake-Up-Jim, at the head of Trail creek, is to have a stamp mill and cyanide plant.

It is expected that the Rox (Sixteen to One) M. Co. will resume May 1, when there may be sufficient water for the mill; if not, the mill will be run by electricity. When work is resumed it is thought there will be employment for 150 men.

A strike is reported on the Black Horse property, 5 miles east of Murray—a vein of ore 3 feet wide. The property is owned by Manley and Pettiford.

#### Washington County.

The mining men of the Big Creek section are agitating a State road into that district from Warren, the road to be built jointly by the State and citizens of the district.

The Pueblo group, of which I. H. Friar is superintendent, is on Smith creek, in the Big Creek district. He has had five men at work this winter and has sunk a shaft 80 feet and drifted 60 feet from the bottom; 50 feet of this drift is in ore assaying from \$2.80 to \$570.40 per ton. It is free milling and the richer ore lies in bunches. Mr. Friar states that he has shaken some of this over a canvas and the gold would drop from it. They have other tunnels in the group that are being driven but have not reached the ore. The company will put a 10-stamp mill in this season.

### MISSOURI.

#### Jasper County.

(Special Correspondence).—The Kansas City-Joplin M. Co. has a mine on the Schifferdecker land at Chitwood and has resumed operations.—Patten & Dodge of Joplin have started their new \$12,000 electrical mill on the Vancil land, south of the city. Power for the mill will be furnished by the Spring River Power Co. The Patten & Dodge mill is the first in the district to use electricity.—A large body of high-grade zinc ore has been struck at the Holy Smoke No. 2 mine at Carterville.—A good zinc prospect is being opened up on the Stickney lease, north of Webb City, by W. H. Scott & Co. The mine for the past two months has made three tons per shift with five hand jigs. A new mill will probably be erected at the mine this summer.—The lease of 140 acres of land on the Billingslea, Law & Dick land, 2 miles west of Neck City, owned by Malang & Phillips of Joplin, is being developed and is proving rich.—The American Lead & Zinc and the Yellow Dog mines at Carterville will install new screens at their mills.—The Amazon M. Co.'s land, comprising 560 acres, near Joplin, owned by C. M. Wilson of Joplin, will be developed. There are six companies holding leases on it.—Several new concentrating mills will be erected in the vicinity of Carterville and Webb City this spring, and work in the mines there promises to be lively in both prospecting and producing. The mills which it is now assured will be erected are those of Ball & Gunning at Neck City; Luke & Brown at Alba; John Durby at Alba; Portland M. Co. on the South Portland at Webb City; George W. Moore et al. on the Jewel C lease on the Missouri Zinc Fields ground at Webb City; the American Zinc, Lead & Smelting Co. on their Blanket vein ground at Carterville.—F. M. Weeks of Colorado Springs, Colo., is in the district, organizing a company to prospect and develop his 120-acre mineral tract, near Carthage.—The Hancock M. Co. of Joplin, which purchased the Sunset lease, is sinking a shaft on a drill hole which showed a rich run of zinc ore. The lease is a part of the Murphy land, 1 mile southeast of Joplin.

Joplin, Feb. 27.

### MONTANA.

A stipulation has been entered into between Attorney-General Galen, representing the State, and W. F. Meyer, attorney for H. Griffith of the Gebo coal mines, that were closed by the State by injunction proceedings on the ground that the law was not being observed, that will permit the resumption of work. The stipulation recites that the company will within thirty days comply with the demands of Coal Mine Inspector Welsh. The resumption is chiefly allowed that coal, which is very much needed, can be mined.

#### Fergus County.

J. A. Drake of Chicago has taken up his bond on a portion of the North Moccasin properties. This was done after 4000 feet of diamond drill prospecting. The North Moccasin lies between the Kendall and Barnes-King mines, which have yielded enough to make Fergus the banner gold producing county of the State.

A rich strike has been made in the Liverpool mine, 15 miles south of Helena, one car of ore yielding \$25,000. The ore averaged 8000 ounces of silver to the ton. The mine is operated by T. G. Merrill of Salt Lake and a Mr. McAuley of New York.

The Montana New Mines Co., operating the sapphire mines, produced \$350,000 worth of gems last year.

A strike has been made in the extension of the Bertha mine, near Wickes, three 6-inch veins being uncovered, which averaged \$100 a ton in gold.

#### Flathead County.

Reports from Snowshoe mine, near Libby, in which Spokane men are interested, are to the effect that the company has decided to sink 250 feet deeper. One hundred and fifty men are at work developing the group.

If development is satisfactory the property is to be further equipped with machinery.

#### Granite County.

S. I. Riches, owner of a parallel lead to the Nancy Hanks claim at Garnet, has had the initial carload shipped from his claim, which netted \$10,000, the values being in arsenical pyrites. The Mitchell & Mussigbrod properties in the same district are said to have \$150,000 worth of similar ore blocked out.

#### Jefferson County.

Gold ore running \$20 a ton has been found in the properties of the Gold Rose Co. Development has shown the vein to be 50 feet wide. A rich streak in the Blue Jacket, an adjoining property, shows ore assaying \$360 a ton. It is the intention of the companies to put in a cyanide plant for the treatment of the low-grade ore.

#### Lewis and Clark County.

Secretary Edgerton of the Bald Butte Co. has issued the annual report, which confirms recent reports of rich strikes in that property. The Bald Butte was for years the leading gold producer of the State. It was then reported worked out. The report of Mr. Edgerton shows that two new veins have been discovered, which yield richer ore than did the two which made the property famous. The 30-stamp mill began operations on Feb. 20, and enough ore is said to be in sight to keep it busy for a year. Nearly \$30,000 was expended in development work last year, but the operations showed a profit.

#### Madison County.

R. C. Knox, manager of the Revenue M. Co., Virginia City, tells the Madisionian that when the Revenue mine work resumed it will be worked by the leasing system entirely. He thinks that is the most co-operative way a mine can be worked, as he claims the miners then share in the profits of the mine. On the lower levels, where there is some dead work to be done, the company will board the leasers and furnish all material except sharpening the steel, while the dead work is being carried on or until the ore bodies are encountered. The basis of rates is as follows for the Revenue and Monitor mines, showing the possible earning for lessees:

Ore Value Per Ton	Lessee's Returns Per Ton	No. Tons Per Day	Bring Lessee Per Day
\$ 7.00	\$2.00	3	\$ 6.00
8.00	2.75	3	8.25
9.00	3.50	1½	5.25
10.00	4.00	1½	6.00
11.00	4.50	1½	6.75
12.00	5.00	1½	7.50
13.00	5.25	1½	7.87
14.00	5.50	1½	8.25
15.00	5.75	1½	8.63
16.00	6.00	1½	9.00
17.00	6.25	1½	9.37
18.00	6.50	1½	9.75
19.00	6.75	1½	10.12
20.00	7.00	1½	10.50

These figures are only approximate and will have to be improved upon in some places of the workings.

#### Missoula County.

The King & Queen M. Co. has been incorporated to operate the claims of the company near Carter. The claims are said to contain pay copper and gold ore.

#### Silver Bow County.

(Special Correspondence).—It has been reported that the copper output of the Butte district for 1905 will show a material falling off and that Montana must look to the copper resources of the Corbin district in Jefferson county, if she desires to keep up her record. To those who know the facts this is amusing. There are promising copper prospects in the Corbin district, but they have not as yet passed beyond the prospective stage, and the outlook for a material production from them is at this time a remote contingency. On the other hand at least three producing mines have been added to the list in Butte within the past year, and a full knowledge of the underground condition of Butte's mines makes it possible to predict a very probable increase in tonnage and output of metal in 1905. Concerning the settlement of the surface on which the city of Butte is built, no mining operations whatever are actually in progress now within 100 feet of the surface, and the settlement which has occurred in the past is by no means such as to cause any alarm. Only a very small part of Butte is undercut by any considerable amount of mining development, and this at such a great depth as not to affect the surface more than in a very slight way.

Butte, Feb. 25.

At the Washoe smelter in Anaconda there is being constructed the largest copper furnace of its kind in the world. Its total capacity for twenty-four hours will be 1600 tons, including all of the charge except coke. To build the furnace it has been necessary to join two of the ordinary furnaces together. The work is progressing under the direction of General Manager P. Mathewson, Assistant Manager Hamilton and the superintendent of the blast department, S. Gormally.

### NEVADA.

#### Esmeralda County.

(Special Correspondence).—New strikes are being reported daily through this section. A large amount of milling ore is being developed, and several mills are building, while others are in contemplation. Water is being developed by means of wells sunk along the granite contact, between Columbia and Goldfield. The Cimarron claim has a high board fence around it. From this mine was recently shipped 3 tons of ore by express, which, it is said, contained \$15,000 per ton. More people are coming into the district every day, and building is progressing as fast as materials can be secured. The camps hereabouts are greatly inconvenienced by the inability of the transportation companies to handle the freight.

Goldfield, Feb. 26.

(Special Correspondence).—The Silver Star mine, comprising the Douglas group, 7 miles west of here, has been sold by C. D. Van Duzer and associates for \$50,000—\$10,000 cash, \$20,000 in thirty days and \$20,000 in sixty days. The Bounce mine, the property of the Lothrop-Davis Co., is also sold for \$22,000 cash.

Sodaville, Feb. 27.

## Eureka County.

C. Allen has a lease and a bond on the Oneonta mine, near Cortez.

## Lincoln County.

De Lamar's mines at De Lamar are to have an extensive cyanide plant for the treatment of tailings. The proposed plant will be capable of treating 20,000 tons of tailings per month. Thirty leaching tanks will be installed, of which eighteen will be of steel, the remainder of wood. The material will pay an average of \$2 per ton, according to the statement of Manager Swindler. There will be no crushing, while the material will be handled along the most inexpensive lines. To the ordinary method of leaching, Mr. Swindler has added a number of devices that promise a close recovery. It is thought that the cost of treatment will not exceed 60 cents per ton.

Scott & Miller of Boston, who recently bought the Abe Lincoln mines and mill at Pioche, and got a bond on the Mendah property, are credited with intention to expend possibly \$200,000 in Pioche, this to include the purchase price of the mines and their equipment. The milling ores are now being tested.

## Nye County.

A new strike of importance is reported in the Midway mine at Tonopah. It is said that in the congestion on the railway at Reno there is now tied up 450 carloads of freight, with Tonopah, Goldfield and neighboring camps as its destination. It is said that the railroad will be into Goldfield within the next four months, while the broad-gauging of the system is progressing as rapidly as possible.

A shipment of high-grade ore has been made through Wells-Fargo from Tonopah. The ore was from the Tonopah-Extension and the Midway mines.

The News says that the Carson & Colorado railroad is broad gauged to Wabuska. Narrow gauge cars will not be run farther than that point in the future. The Southern Pacific company will arrange for through service from Wabuska to Sparks. A joint traffic arrangement will be made with the Virginia & Truckee railroad whereby the Southern Pacific trains will run through over the Virginia & Truckee tracks from Mound House to Reno. The Southern Pacific is figuring on running a line from Sparks, to tap the Virginia & Truckee road at Huffaker's Station. Preferred runs are to be given with broad gauge trains running from Wabuska to at least Mound House. Standard gauge engines and other equipment are arriving for the operation of traffic in that territory. Surveyors have been in the field running a line from Wabuska for the straightening of the road. The new work will soon commence of broad gauging to Sodaville, but under the reconstruction Hawthorne will be off the new line about 3 miles.

The Tonopah Railroad company will make their road standard gauge in time to operate trains when the Southern Pacific get their reconstruction work to Sodaville.

The Goldfield News reports a number of new strikes, and that the list of shipping mines is increasing.

The Combination company is sacking from the shoot opened at surface, 200 feet south of the shaft. The shoot is 18 inches wide, and will average \$300 per ton. Thirty inches of sulphide ore, carrying gold, have been exposed in the shaft on the Spearhead at a depth of 104 feet.

At the Florence, in the north drift, the ledge has widened to 16 feet and 5 feet of high-grade shipping ore is being broken. The output is 10 tons daily. The shaft is being put down to the 300-foot level. With stopping under way the entire 16 feet of ore will be broken down and extracted.

The Adams district now awaits better milling facilities.

A mill of 40 stamps is proposed for Goldfield, to be built by the H. L. Frank company of Butte, Mont. G. R. Potter is manager and Frank Enzensperger, superintendent of construction.

Mr. Enzensperger will first ship in machinery for a testing mill, to work five-ton samples. If necessary all branches of ore reduction from amalgamation to chlorination will be taken up. It is the company's present intention to put in a 40-stamp mill when the experimental stage has been passed. The location of the mill has not been decided on, several available sites being under consideration.

## Washoe County.

J. Gregory of Olinghouse has leased the Addie C. to Golding, Fraser & Wetmore of Wadsworth for \$25,000. The Springfield M. Co. is piping water to their claims.

## NEW MEXICO.

## Grant County.

The second furnace of the Silver City Reduction Works has been blown in for a trial run. The ore supply at the smelter has been cut short owing to the bad condition of the roads, and until there is some improvement, the second furnace will not be put in commission. The new 250-ton furnace for the smelter has been shipped and the foundation for the engine to run the blower has been completed. The Whitewater Copper Mining Co., C. P. Laughlin, manager, will resume development of its fifteen claims in Whitewater canyon, Burro mountains. The tunnel on the Black Hawk will be run 200 feet, as the surface showing is good.

Regular shipments are being made from the Arizona and Manhattan at Pinos Altos by L. P. Deming, who has leased the properties, but the bad roads will compel cessation of the shipments for the present. The shipments average from ten to twelve tons daily.

Manager Brandis has started up the Mammoth mill, 1/2 mile north of Pinos Altos, and is running on ore from the forty leasers on the Comanche property. The ore is crushed by the stamps and run on the tables, where it is concentrated. The concentrates are shipped to the Silver City Reduction Works. The mill was built twelve years ago to treat the ore from the Mammoth mine.

The Detroit Co. has received three carloads of machinery for the placers in Whitewater canyon, 1 mile below Fort Bayard.

Work has been resumed on the Hanover mine by

Phelps-Dodge Co. The property was acquired by the company several years ago, but permitted to lie idle. Now shipments will commence to the smelter at Douglas, Ariz. There are also 25,000 tons of ore on the dump, which will be shipped.

The Colorado Fuel and Iron Co. is employing 125 men at its Fierro mines.

A high-grade streak of lead sulphide, carrying silver values, has been opened up near the Old Man mine; assays run as high as 500 ounces of silver and 40% lead to the ton.

A 35,000-pound No. 6 Root blower is being installed at the Comanche smelter at Silver City. From its Burro Mountain and Pinos Altos properties the company is making regular shipments to its smelter. At the former property several 500-foot shafts are in progress.

## Otero County.

A smelter for Alamogordo is being discussed. W. A. McIvers, a mining man of Lincoln county, says all conditions are favorable. In the Gallina mountains is a large amount of copper-lead ore; the Jack mountains have great quantities of iron and copper ores, and the Jicarilla district, gold, copper and iron. Lone Mountain, near White Oaks, carries iron in abundance and some copper, and the White mountains contain copper, gold and lead ores. The Ocuras district has good copper propositions and the San Andres, copper and lead. For fuel, the White Oaks and Patos fields, when opened, would supply the demand for coal and coke for years, beside the Capitan and Dawson fields and the Hagan field, the latter tributary by the Santa Fe Central connection. Alamogordo has water and railroad facilities. Mr. McIvers is opening large bodies of copper and iron ore in the Jicarilla district for a Wisconsin company. He says the mines must have a smelter this year.

## OREGON.

## Baker County.

J. W. Long, who has been examining the California mines in Cable Cove district, thinks that with proper operations it will become a prominent producer. The California group is composed of twenty claims, upon which a large amount of development work has been done. A large mill has been built by the company, but he thinks it is equipped with the wrong kind of machinery for treating the ores. In the mines about 4000 feet of tunnel work has been completed. The ore body ranges from 10 inches to 4 feet in width and will assay about \$65 per ton.

The Iron Dyke mine and Northwest Railroad, on Snake river, are reported to have passed back into the control of C. M. Reed and Mrs. Shatto, and through them the property will be conveyed to the Standard Oil Co. by H. H. Rogers. It is said that Rogers has secured control of the Searles mines in the Cornucopia district, and that the Standard Oil will hereafter predominate the interests of the mining camps to the east of Baker City, covering especially the gold and copper producers and the transportation down the Snake.

## Benton County.

The Freeland Con. M. Co., with headquarters at Salem, is preparing to develop its properties in the Santiam district. It is the intention to install a leaching plant this season. F. H. Colpitts, who has been in Colorado for a year making a study of leaching plants, has recently become interested with the company and is directing work. The company owns ten claims on Gold creek, a tributary of the Little North Fork of the Santiam, about 18 miles from Gates, on the Corvallis & Eastern Railroad. There is considerable ore in sight in the mine workings.

## Douglas County.

At the annual election of directors and officers of the North Fairview M. Co. at Eugene, a report of conditions was rendered and plans discussed for future operations. The company has 1800 feet of tunnels, the longest one of which is in 400 feet. Good values are found at this depth, the ore being mostly free milling.

## Grant County.

At Prairie City, the Dixie Meadows management will resume milling. There is a hard blue quartz in a part of the higher grade rock. This, when mixed with the heavy talc on the foot wall, presents a difficult milling problem. The 60% of values carried in sulphides further complicates the case.

## Jackson County.

The new 10-stamp mill at the Lucky Queen mine in the Gold Hill district is about completed.

D. B. Grant has bought the Sweepstake Extension claim of T. W. Hill on Wagner creek.

The Oregon Belle mine is to have a new stamp mill to be operated with electric power.

A. C. Hooper of the Mt. Pitt M. Co. states that he has eight men at work and are running their arrastra night and day with good results, and that on their placer mine on Bummer gulch they have a No. 1 giant at work, operated by 400 feet of 8-inch pipe under 100-foot pressure.

The Enterprise M. Co., near Woodville, are preparing to start their mill. F. Trowbridge of Baker City is manager. This company is operating the old Homestake mine.

At Woodville the Homestake will resume. Superintendent Trowbridge thinks steam power can be dispensed with, and electric energy from the Gold Ray line taken when the line is completed en route to Grants Pass. The property is owned by the Enterprise M. Co.

The Oregon Belle property, near Jacksonville, is to have a stamp mill. Foster and Gunnell are managers.

## Josephine County.

The old Jewett mine on Mount Baldy, near Grants Pass, abandoned for a long period, will be opened up again and developed by underground workings, and equipped with a reduction plant, cyanide tanks, etc.

The 100-ton smelter at Taklima will start up next month. The smelter has a capacity of 120 tons daily and will be operated full blast. Men are employed in both the Queen of Bronze and Cowboy mines blocking and removing ore as a reserve supply for the smelter.

## Lane County.

Near Cottage Grove the Vesuvius 10-stamp mill has

been closed for the present. Superintendent Jenks reports that the lower tunnel is progressing rapidly.

At Blue River, C. Parks, manager of Treasure mine, will put in a milling plant. He says the first mill will be an experiment, and later will build a larger one.

## SOUTH DAKOTA.

## Lawrence County.

(Special Correspondence).—The district from 4 to 7 miles south of Perry, and about half way between Perry and Rochford, is attracting attention as a field of unusual prominence. The Montezuma mine on the south and the Clover Leaf on the north, are characteristic of a large part of this area. The formation is largely hydro-mica schist of deep red color, similar in appearance to that on the surface on the Homestake belt, and quartz veins and silicified zones are of frequent occurrence. Moreover, in early days considerable placer gold is said to have come from the tributaries of Box Elder creek, which drains this region. About 3 miles north of Rochford copper prospects are good, but have received only superficial development. The formation is black slate and quartzite. The section is not well watered by large streams, which is probably the principal reason why more prospecting has not been done here. Rochford, Feb. 24.

The Myrtle Dell M. Co. was recently organized and incorporated under the laws of South Dakota, says the Miner. The officers are: W. I. Harmon, president, and J. J. Donnelly, secretary and general manager. The company owns 17 locations in the Ragged Top district, between Crown Hill and Spearfish canyon, near Preston. The Burlington road from Englewood to Spearfish is accessible to the group, and there is a millsite on the claims. The principal development consists of a shaft and three tunnels in ore. The company has several buildings on the mine. The shaft is down 132 feet in a phonolite dyke. A tunnel 1000 feet southeasterly from the shaft has been driven in an easterly direction 168 feet with a view to tapping the dyke in a different place. Another tunnel is being run to tap the dyke farther west from tunnel No. 1, about 350 feet from where a small gash is known to exist. Tunnel No. 3 is being driven north to tap the dyke. Work is now in progress.

At a recent meeting of the Black Hills Mining Men's Association, C. W. Merrill, metallurgist of the Homestake Co., said that ore was being crushed in the Amicus mill, 240 stamps, operated by the Homestake Co., for 13 cents per ton. The ore is crushed to a 35 mesh. The Homestake Co. is now treating ore that averages \$3.70 a ton.

## UTAH.

## Beaver County.

Manager M. M. Johnson of the exploration department of the Newhouse mines and staff are making a careful sampling of the properties of the Majestic C. M. & S. Co., near Marysville, with a view to ascertaining what the needs of the properties are. The Old Hickory and Harrington & Hickory belong to the Majestic.

The Horn Silver zinc plant at Frisco, which cost about \$200,000, has begun operations. In the Horn Silver mine is considerable zinc ore. Should this prove satisfactory the Daly-Judge mine will also install similar equipment.

## Juab County.

Tintic ore shipments for the week ending Feb. 25th were as follows: Centennial Eureka, 48 carloads; Bullion-Beck, 6; Gemini, 13; Ajax, 4; Carisa, 3; Grand Central, 5; Mammoth, 10; Victor, 3; May Day, 2; Uncle Sam, 2; Yankee Con., 5; Eagle & Blue Bell, 9; South Swansea, 2; Star Con., 3. Total, 104 carloads.

## Salt Lake County.

The North Bingham M. Co. has incorporated; capitalization, \$50,000; J. E. Frick, president; G. L. Bemis, treasurer; F. O. Frick, secretary; F. Bemis, vice-president.

Manager D. C. Jackling of the Utah Co. says of the new tunnel connecting with the All's Well mine that the length of the tunnel is about 1800 feet to where it connects with the shaft, and gives us an outlet to the surface in two places, and also enables the extraction of ore from the All's Well ledge through the main tunnel workings. It is not the intention at the present to draw on the All's Well for ore, not at least until we continue the drift already started 200 feet farther and do some more crosscutting. The shaft is 120 feet deep, but back of it the workings on the ledge will make depth rapidly, as the mountain soon becomes precipitous. From the All's Well shaft to the Ohio side lines the distance is about 600 feet, and there is ore all the way.

The local rumor that the Ohio Copper Co.'s Bingham properties are about to pass into the hands of the Guggenheim Exploration Co. of New York is denied by Manager Catrow of the Ohio properties. It is reported in New York that control of the interests of the Guggenheim Exploration Co. will pass into the hands of the American S. & R. Co.

At the Utah & Eastern mine, when sinking of the double-compartment shaft is finished, the smelter will resume operations.

## Summit County.

The Daly-West meeting in Denver showed the mine to be in good shape. The treasury reserve is reduced to \$284,148.45, or \$190,847.83 below what it was at the beginning of the year. Of the \$170,000 decrease in revenues, or difference in treasury reserve, over \$100,000 went into the construction of the wrecked ore bins, mill enlargement and machinery purchase account, leaving \$50,000 to be charged to dividend account. The receipts of the company from all sources during the year were \$2,280,139.75, as against \$2,643,747.52 during 1903, a decrease of \$363,697.77. From the sale of ores and concentrates the company received during the year \$1,804,673.83. The figures show that the concentrates and crude ore produced were both worth more per ton than they were in 1903, the better work of the mill being reflected in concentrates worth \$4.10 per ton more than during the year previous. Of the regular grade of crude ore, 23,355 dry tons were shipped. It contained 1,023,831 pounds of copper, 11,335,964 pounds of lead, 1066.50 ounces gold and 1,578,924 ounces of silver, which sold for \$885,169.30. During the time the Quincy works were operated 14,440

tons of ore, carrying 450,452 pounds of copper, 4,547,278 pounds of lead, 692.33 ounces gold and 625,168 ounces silver, was sold for \$305,600.75. The concentrates produced amounted to 15,207 dry tons, containing 541,340 pounds of copper, 9,616,557 pounds of lead, 607.88 ounces gold and 848,652 ounces silver, which sold for \$605,738.65. A new product, known as mill crude, which comes from the sorting belts introduced into the plant a few months ago, amounted to 267 tons. This ore carried 7382 pounds of copper, 151,665 pounds of lead, 9.59 ounces gold and 11,490 ounces silver, and sold for \$8164.13, or \$30.58 per ton, net. The concentrates brought \$39.83 per ton, the Quincy crude \$21.16 and the regular crude \$31.22 per ton. The total dividends paid this year amounted to \$1,044,000, while the total paid to date by the company is \$4,635,000. This is practically 50% of the mine's production from the beginning, which has been \$8,955,512.07.

## WASHINGTON.

### Stevens County.

Superintendent A. I. Goodell of the Northport smelter has started an extra furnace at the Northport works, making three of the five furnaces of the Le Roi smelting plant.

## FOREIGN.

### BRITISH COLUMBIA.

The employees of two smelters are on strike as the result of the defeat of the bill for an eight-hour day. The men from the Greenwood and Boundary Falls plants in the Boundary country are out, and it is expected that before the end of this week there will not be a smelter running in full blast in the province. The men think they can follow the tactics of the miners who secured an eight-hour day several years ago after a long and bitter strike. The other smelters, where it is feared trouble may come early this week, are the City Hall mines smelter at Nelson, the Canadian smelting works at Trail, the Tye and Crofton smelters on Vancouver Island, and the Granby smelter at Grand Forks. There are over 1000 men engaged in the smelting institutions in this province. The owners are determined not to give in, so that a long struggle is feared.

It is expected that smelting at the new plant of the Sullivan Group M. Co., at Marysville, will begin next week. The second furnace—a duplicate of the first, with a capacity of 200 tons of lead ore daily—is expected to be running April 1.

### Boundary District.

It is said the automatic electric feeding device installed at the Granby smelter will save the labor of eighty men.

Returns from the last car of ore sent out by the Sky-lark to Nelson smelter returned \$93 per ton.

It is stated that 375 feet of drifting and 140 feet of crosscut in the new shoot of ore in the Mother Lode mine has failed to show any walls.

Drifting is now in progress north and south from the 45-foot level of the Bay shaft. A large amount of free gold and tellurides continues to be found in the ore. Shipments will be made.

The recent shipment of twenty-four tons of ore from the Sally mine, west fork of Kettle river, treated at the Trail smelter, ran over 200 ounces silver, besides small gold values. Shipments will be maintained all winter. There are large reserves of ore on the dump.

### Cariboo District.

(Special Correspondence).—A specimen of the scheelite (tungstate of lime) especially reported to the MINING AND SCIENTIFIC PRESS of Jan. 28, as having been discovered near Barkerville, this district, has been brought down from Hardscrabble creek by H. H. Cleugh, a miner. The sample consists of a small bottle filled with a sand composed of small irregular grains of quartz, colors of gold and specks of magnetite or hematite. It occurs in a seam coming through the slate formation of the district. The seam varies in width from 4 inches to 4 feet. Next to the seam is a quartz ledge, and it is inferred that the seam itself is not a filled fissure, but that a portion of the quartz through which it is said the scheelite is disseminated has become decomposed. The portion of the quartz ledge not so affected has remained hard, though it has been ascertained by breaking the quartz that the scheelite is distributed through it in veinlets. There is no quotation for scheelite given so far as known, but it is stated that it is worth 60 cents per pound, and that additional value is given to the mineral because of a deposit of hematite in the district. The mineral is used in the manufacture of steel. Mr. Cleugh is forwarding the sample to the Toronto University for analysis. About 200 feet, according to Mr. Cleugh, have been uncovered.

Barkerville, Feb. 24.

Forty ounces of coarse gold from the Hardup claim on Grouse creek have thrown Barkerville into excitement. The gold goes \$20 to the ounce, and this display of \$800 worth from a claim that was considered worked out has set the old timers thinking. J. Wendle obtained the gold in nuggets varying in size from \$75 to pieces worth a few dollars. It is thought that Wendle has found accidentally the famous Heron lead, which in the early days of Cariboo yielded rich returns. Of late years little has been done on Grouse creek, except by the Waverly Co., which paid a dividend in 1904.

### Lardeau District.

The Lucky Boy is being reorganized and is to be known as the Chestnut Hill M. Co. The Lucky Boy is shipping ore.

At Camborne the Eva mill has resumed and forty men employed in mine and mill. At the Oyster-Criterion mill, owned by the Great Northern Mines, Ltd., preparations are making for adding ten stamps. On the Silver Dollar, of which J. A. Darraugh is manager, a compressor plant and concentrating mill is being put in. On the Beatrice, near Camborne, a large force is employed, considerable ore is being taken out and rawhiding is in progress. The ore of the Beatrice is high grade and will stand an expensive haul.

### Kootenay District.

J. R. Bottorff, representing the American M. Co. of

Elwood, Ind., has secured hydraulic leases and plant on French creek, Kootenay, from W. Cowan. The new American owners will begin work at once. The flumes and the headgates are being repaired and the plant overhauled.

### Rossland District

It is reported at Rossland that a new ore shoot has been found in the White Bear mine. It was found in an upraise, making from the 1000 to the 700-foot level. The ore is high-grade, and ten carloads have been extracted. It is thought the shoot is extensive, and will go into ground that has not yet been explored.

The total shipments from Rossland for the past week were 6315 tons, while the total for the year to date was 46,666 tons.

A mining deal has been completed at Revelstoke whereby the American M. Co. of Indiana acquires the leases and hydraulic plant on French creek. With this new concern at Revelstoke this season there will be four American companies operating placer leases in the Big Bend gold fields.

The new crusher of the Mother Lode, near Greenwood, with a daily capacity of 900 tons, has been put into commission. The former crusher will be removed to a site beside the new one and repaired in time to meet the increased demand to ensue upon enlarged smelter facilities.

Fine copper ore is being shipped from a 30-foot ore body in the Emma.

## MEXICO.

### Chihuahua.

W. C. Greene of Cananea is reported to have bought the Santa Juliana gold-silver mine in the Ocampo, or Jesus Maria district. It is expected that its purchase by Col. Greene, together with 46,000 acres of timber land, other mines and the water power of the Falls of Basichic, will put new life into the Jesus Maria camp, which has been a regular producer since 1816 when it was discovered. The price is said to be \$438,000 gold. It was bought from the Belvanera M. Co., in which J. C. Beatty was prominent.

For eighty-eight years the camp has been producing at a profit with a 90-mile pack haul to overcome, and until the Chihuahua & Pacific was built to Minaca in 1899, all supplies went from this city, 125 miles farther.

### Coahuila.

Construction work has begun on a smelter at Saltillo. The Mazapil C. Co. has a concession from the State, which has donated the site and water supply for the undertaking and also other privileges, such as the exemption from certain taxes.

The smelter is being built southeast of the town, near the crossing of the Coahuila and Pacific and National lines. Concepcion del Oro, San Pedro de Ocampo, Mazapil, and other mines will send their products to this smelter.

This smelter project was first promoted, fifteen years ago, but the proposition has always hung fire till now.

### Oaxaca.

The Chihuahua Enterprise learns that T. I. Ryder, who holds the concession for a smelter in Oaxaca, will commence work for the erection of the plant within sixty days. It is claimed that the site is purchased. He has resigned his position as manager of the Waters-Pearce Oil Co. to take effect April 30, after which time he will devote himself to the smelter enterprise.

### Sonora.

The Transvaal smelter, located 15 miles west of Cuppas, in the Moctezuma district, has been blown in. L. Cloud, formerly of Nogales, is general manager, and O. H. Neahr, superintendent.

H. C. Gerber is at Toledo, where the smelter is blown in and operations resumed. Mr. Gerber, formerly of Parral, is general manager, and J. Barney, assistant.

W. E. Jones of the Cerro Azul M. Co. has returned to the company's properties in the Cerro Azul mountains to resume operations with a large force of men.

## NEW ZEALAND.

Returns for the year show a slight falling off in the gold hullion output. Apart from this apparent decrease in the gold return, the industry has been advanced.

During 1904 the Auckland gold fields produced hullion worth £834,880, as compared with £902,503 for 1903.

The Waihi G. M. Co.'s mine has produced to date £632,256, as against £618,699 for a similar period of 1903.

## Personal.

GEO. G. MERRICK of Denver, Colo., is now at Monte Cristo, Ariz.

H. H. MCCARTHY is now manager of the Golconda mine, near Sumpter, Or.

G. R. HANCOCK is manager of the Ferry-Hancock properties, Park City, Utah.

RICHARD A. PARKER, E. M., has returned to Denver, Colo., from Salt Lake, Utah.

C. H. DOOLITTLE is now manager Bingham-New Haven mines, Bingham, Utah.

W. E. THORNE is now in charge of the Snow Storm Hydraulic M. Co., Fairplay, Colo.

THE Gold Roads mine, Kingman, Ariz., is now under the management of H. G. Heffron.

T. K. CODE is superintendent of the Empire mine, near Downsville, Sierra county, Cal.

ATWOOD BENTON of Parral, Chihuahua, Mexico, has returned from a trip to Denver, Colo.

J. PINKHAM has been appointed assayer Boise, Idaho, assay office, to succeed H. S. Wooley.

H. J. MEISEL, M. E., formerly assayer at the Rawhide mine, Tuolumne county, Cal., is now connected

with the New York & Honduras Rosario M. Co., San Juanito, Honduras, C. A.

O. W. PIERCE, formerly of Lake City, Colo., is now with the S. H. Supply Co. of Denver, Colo.

C. H. FULTON succeeds R. L. Slagle as president of the State School of Mines, Rapid City, S. D.

FRANZ MEYER is planning a smoke-consuming plant for the Utah Con. smelter, near Murray, Utah.

LEWIS SEARING, manager of the Denver Engineering Works Co., has returned from New York City to Denver, Colo.

F. A. O'HAGAN of the A. S. Cameron Steam Pump Works, New York City, has returned there from Denver, Colo.

WM. BAINBRIDGE, superintendent of the El Paso Con. G. M. Co., Elkton, Colo., has returned there from Denver, Colo.

S. I. HALLETT of Colorado has returned from Brazil and is visiting the Dos de Abril mine of Heffran & Piper, Chihuahua, Mex.

FRANK ENZENSBERGER, superintendent of the H. L. Frank Co. of Goldfield, Nev., is in San Francisco, Cal., arranging to buy a mill for his company.

R. C. TURNER of San Francisco, Cal., has gone to the Dolores mine, Chihuahua, Mex., to relieve Manager Hardy, who takes an extended vacation.

R. A. TREVARTHEN, former manager Portland mine on Battle mountain, now has charge of the Forest Queen property, Ironclad hill, Cripple Creek, Colo.

HANK SUMMERS, first mayor of Nome, is in Goldfield, Nev. While in Alaska he cleared up \$460,000, which he lost in other ventures. His pocketbook was so thin that he walked from Tonopah to Goldfield. He has located several properties at Lida, and hopes to make another fortune.

## Trade Treatises.

Steel Wheelbarrows is part of the story told by the Archer Iron Works, 34th Place and Western Ave., Chicago, Ill., in their booklet thereon.

"Westcott Chucks," standard, 6x9, red and gold, 32 pages, bound, illustrating lathe chucks and drill chucks. Westcott Chuck Co., Oneida, N. Y.

Catalogue No. 20 from the Allis-Chalmers Co., Milwaukee, Wis., graphically portrays their Reynolds Corliss engines in their various styles and designs.

Catalogue 10 A., from Colorado Iron Works, Denver, Colo., treats engagingly of cyanide plants, machinery, tanks and appliances. Every one of its 82 pages is of interest.

Catalogue No. 35, from the S. H. Supply Co., Twenty-second and Larimer, Denver, Colo., contains 100 pages illustrated description of second-hand mining machinery of all kinds.

Catalogue No. 21 of the Weber Gas & Gasoline Engine Co., Kansas City, Mo., describes in detail the Weber suction gas producing plant and the Weber cylinder vertical gas engine.

Publication No. 117, "Gates Rock and Ore Breakers, Styles D and F," from the Allis-Chalmers Co., Milwaukee, Wis., is fully up to the high standard set by that company in its publicity department.

Jos. Dixon Crucible Co.'s "Graphite," a monthly publication, is in a class by itself. It contains good-humored matter as well as technical information, and will be sent from the company's office, Jersey City, N. J., on request.

Wood stave pipe is treated of in an illustrated brochure from the National Wood Pipe Co., 301 Market street, San Francisco, Cal., and Sixth and Mateo streets, Los Angeles, Cal., with testimonials of merit thereof, and descriptions of recent installations.

"The Yellow Streak" is the unique title of a lemon colored leaflet issued by the Broderick & Bascom Rope Co. of St. Louis, Mo. Primarily advertising that firm's make of wire rope, it incidentally gives additional information. Among other things is brought out that at the St. Louis Exposition they were awarded the grand prize on wire rope.

The Hardsocg Wonder Drill Co.'s latest catalogue describes in detail the Little Wonder air hammer rock drill. The booklet will be sent on request from the main office of the company, Ottumwa, Iowa, or their representatives, Rix Compressed Air & Drill Co., San Francisco, Cal.; H. L. Sinclair, 1744 Broadway, Denver, Colo.; H. P. Fogh, 1602 Railroad avenue, Seattle, Wash.; Irish & Chandler, 119 1/2 So. Spring St., Los Angeles, Cal.

Harron, Rickard & McCone, 21-23 Fremont St., San Francisco, Cal., have issued a third edition of their catalogue No. 5, "Hydraulic Mining Machinery," illustrating and describing the Campbell gravel elevator, water lift, mining giants, sluices, riffles, water gates, pipe, etc. Some carefully prepared tables regarding flow of water, loss of head in pipes by friction and other technical data are a notable part of the treatise which forms the latest addition to their list of issued catalogues.

## Obituary.

OSCAR O. BENSON, a pioneer of Granite district, Or., died February 22 at Portland, Or., from a surgical operation. He was at one time one of the principal operators of the Red Boy mine, near Sumpter, Or.

## Commercial Paragraphs.

THE advertisement of the Ingersoll-Sergeant Drill Co. in this issue was first choice in the advertising contest recently conducted by the publication department of that company.

J. L. STANNARD of the National Wood Pipe Co., who has just completed a large installation in western Washington, has gone to Olympia, Wash., where the company is about to put in a large manufacturing plant.

CHAS. W. CROSS, M. E., E. E., formerly of the Roberts & Abbott Co. of Cleveland, Ohio, has entered the employ of Crocker-Wheeler Co. of Ampere, N. J., and is attached to the Cleveland office of the company, 816 New England Building.

J. D. HELM has resigned the superintendency of the Penoles M. Co., Mapimi, Mexico, and will be manager of a branch house in Mexico City of the Power & Mining Machinery Co. of New York. He is succeeded at Mapimi by O. R. Whitaker of Denver, Colo.

W. R. PERRIN & Co., Forty-sixth and Loomis streets, Chicago, Ill., have installed a large filter press in the plant of the Echo M. Co., Mojave, Cal. It is a 40-inch hydraulic closing press, 32 feet long, with fifty 3-inch chambers. It weighs twenty-five tons. It is operated by a belted hydraulic pump.

N. C. BONNEVIE has returned to Denver, Colo., from a month's trip in the East. The firm of Bonnevie & Lee has been dissolved and N. C. Bonnevie is now conducting the business of same. The Denver Ore Testing & Sampling Co. will be conducted as heretofore. N. C. Bonnevie has been elected president and general manager.

PRESIDENT JOHN C. WHITE, of the Pacific Coast Hardware Dealers' Association, has arranged for the meeting of the members of the Association at the St. Francis Hotel, San Francisco, Cal., from March 8th to 10th. He says the important matter of action then will be upon the proposed regulation of the railway rates by Congress.

THE agency for the A. S. Cameron Steam Pump Works of New York, N. Y., is now held by Cary & Fielding of 1711 Tremont street, Denver, Colo., who state that they will carry in Denver a stock of pumps and repairs. During the past month they report the sale of five Rand compressors of which they are the agents for Colorado and adjacent territory.

CONTRACT for compressed air power plant, to be used in driving the second pair of trolley tunnels under the Hudson river, N. Y., has been awarded to the Ingersoll-Sergeant Drill Co., making a total of thirty-eight Ingersoll-Sergeant air compressors, with an aggregate capacity of 117,234 cubic feet of air per minute, now used in building the various tunnels under the Hudson and East rivers.

C. M. FUELLER, 1752 California street, Denver, Colo., is receiving bids on lumber and other material for a 300-ton cyanide plant to be erected at Silver Cliff, Colo., for J. W. Northrop of Chicago. This is said to be the first mill in the State to adopt fine crushing. After the ore goes through the crushers and rolls it passes through tube mills, and crushed fine, and then put through filter presses. Mr. Fueller will have charge of the construction work of the mill.

COLORADO IRON WORKS CO. of Denver, Colo., reports the following orders and shipments: Complete sampling and smelting plant, with steel building, for the Mowry Mines Co., Arizona; hot blast, copper matteing and smelting plant for the Lost Packer M. Co. in Idaho; shipment of six carloads of material for the 200-ton smelting plant of the National Metallurgical Co. in Mexico; and concentrating machinery, consisting of impact screens and supplies, for the Kootenay Ore Co. and the Jackson Mines Co., Kootenay district, B. C.

WHAT the manufacturers state is the largest high head centrifugal pump ever made in one unit, built by the Byron Jackson Machine Works of San Francisco, Cal., for a large mining company in Oregon, was shipped last week. The pump is of the series five-step type, built to withstand a pressure of 250 pounds per square inch, or a total lift of 580 feet, and is to supply 9000 gallons of water per minute. It is driven by four 400 H. P. turbine water wheels, direct connected, and is made for the purpose of delivering the necessary water to a battery of giants that will operate on gravel deposits.

AMONG recent shipments made by the American Concentrator Co. of Joplin, Mo., they report the following: Complete equipment for a 300-ton copper concentrator for the Union C. M. Co., Copperopolis, Cal.; complete equipment for an entire concentrator to the Carthage M. Co., Carthage, Mo.; to F. B. Holmes, Boulder, Colo.; one New Century crusher and two sets New Century belt-driven rolls; complete concentrating plant for lead and zinc ores to the Monarch C. & M. Co., Barnett, Mo.; complete concentrating plant for treating lead and fluor-spar, consisting of New Century crushing and rolling machinery, to the Cave-in-Rock M. Co., Cave-in-Rock, Ill.

C. S. SIEFERT, representing the La Harpe Smelting Co. of La Harpe, Kan., and the A. B. Cockerill Zinc Co., is in Chihuahua, Mex., trying to purchase zinc ores. He says the zinc fields of Missouri, where high-grade concentrates are made and where the zinc smelters of the States have heretofore been getting their supply, are no longer able to supply the increased demand. The smelters must look elsewhere. The smelters in the natural gas fields of Kansas, where most of the zinc is smelted, until recently would treat very little sulphide ore assaying less than 50% zinc, with a heavy penalty for iron. Now they will handle anything from 25% up, with small penalty for iron, which gives a market for the large bodies of low-grade zinc sulphide (black jack) in the western part of Mexico

and the United States, heretofore thrown away as worthless. Colorado produced \$4,000,000 worth of zinc ore last year and that State is coming to the front rapidly in zinc production. British Columbia has also become a great zinc producer. Since the yield of precious metals has diminished in that country, the Government offers a bounty on zinc ores. Many large bodies of low-grade zinc sulphide, intimately connected with galena, are found in the western part of Mexico, principally in the States of Chihuahua and Durango.

## Latest Market Reports.

SAN FRANCISCO, March 3, 1905.

### METALS.

SILVER.—Per oz., Troy: London, 27½d (standard ounce, 925 fine); New York, bar silver, 60c, refined (1000 fine); San Francisco, 60c; Mexican dollars, 51c, San Francisco; 48½c, New York.

COPPER.—New York: Standard, \$15.60; Lake, 1 to 3 casks, \$15.60@16.50; Electrolytic, 1 to 3 casks, \$15.50; Casting, 1 to 3 casks, \$15.25. San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18@24c. London: £68 5s spot per ton.

The export of copper to China, presumably for the Japanese market ultimately, continues strong as ever from the United States. An authority estimates that the existing contracts call for at least 50,000,000 pounds or more, and he states further that he has no doubt that China absorbed from the United States and Europe during the past six months at least 150,000,000 pounds. Until the war is over there is no prospect of any diminution in the demand.

LEAD.—New York, \$4.60; Salt Lake City, \$3.50; St. Louis, \$4.12½; San Francisco, \$3.70, carload lots; 4½c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5½c; pig, \$4.85. London: £12 5s ½ long ton.

SPELTER.—New York, \$6.20; St. Louis, \$6.30; London, £24 2s 6d ½ ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

TIN.—New York, pig, \$28.60@29.00; San Francisco, ton lots, 30c; 500 lbs., 30½c; 200 lbs., 30½c; less, 31c; bar tin, 32½c@35c. London, £131 ls.

PLATINUM.—San Francisco, crude, \$18.50 ½ oz.; New York, ingot, \$19.50 ½ Troy oz. Platinum ware, 75@82c ½ gram.

QUICKSILVER.—New York, \$40.00@41.00, large lots; London, £7 12s 6d; San Francisco, local, \$38.00 ½ flask of 75 lbs.; Denver, \$45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 19.75c; San Francisco, Plumbers', 100-lb. lots, 16.50c.

ZINC.—Metallic, chemically pure, ½ lb., 50c; dust, ½ lb., 10c; sulphate, ½ lb., 10c.

NICKEL.—New York, 55@60c ½ lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c ½ lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburgh. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburgh.

### STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$16.85@17.10; gray forge, \$16.85; San Francisco, bar, 3c ½ lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburgh, \$23.00@27.00; open hearth billets, \$23.00@27.00; San Francisco, bar, 7c to 12c ½ lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, 1c ½ lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, 1c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LUMBER.—(Retail.) Pine, ordinary sizes, \$24.00@5.00; extra sizes higher; redwood, \$28.00@30.00; latb, 4 eet, \$4.50@5.00; pickets, \$21.00; singles, \$2.50 for No. 1 and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00@35.00.

NAILS.—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.55; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d, Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4d and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

LIME.—Santa Cruz, \$1.25 country, \$1.25 city ½ bbl.

CEMENT.—Imported, \$2.15@2.65 ½ bbl.; California, carload lots, \$2.10 f. o. b. at works; small lots, \$2.40 ½ bbl. in sacks, 4 sacks to bbl., 10c for each sack returned.

### GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 8½c; Hallett's, 8½c; San Francisco, 1000-lb. lots, 9c; 300@500-lb. 9½c; 100-lb. lots, 10½c.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lot, Eastern and foreign: Wallsend, \$7.50; Brymbo, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8.00; Cumberland, \$13.00; Cannel, \$8.50; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13.00 in sacks; Sunnyside, \$8.50, long ton.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1\*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1\*\*, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg. CAPS.—3x, \$5.50@6 per 1000; 4x, \$6.50@7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

FUSE.—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c ½ set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c ½ lb.; carloads, 23@23½c; in tins, 30c; soda ash, \$2.00 ½ lb.; hyposulphite of soda, 3@3½c ½ lb.; caustic soda, in drums, 3@3½c ½ lb.; Cal. s. soda, bbls., \$1.10@1.20 ½ lb.; 100 lbs., sks., 90c@1.00; chlorate of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2½c; powdered sulphur, 2½@2½c; flour sulphur, French, 2½@2½c; alum, \$2.00@2.25; California refined, 1½@2c; sulphide of iron, 8c ½ lb.; copper sulphate, 5½@5½c; chloride of lime, spot, \$2.50@2.75; sulphuric acid, in carboys, 66% B, 1½@2c ½ lb.; nitric acid, carboys, 8c ½ lb.

OILS.—Linseed, boiled, bbl., 55c; cs., 60c; raw, bbl., 55c; cs., 58c; Lucol oil, boiled, bbl., 50c; cs., 55c; raw bbl., 48c; cs., 53c. Kerosene—Pearl, per gal., 19c; As; tral, 19c; Star, 19c; Extra Star, 22c; Ecocene, 21c, Elaine, 25c; Water White, in bulk, 12½c; Mineral Seal iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Minera; Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 16c, do., cs., 22½c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphta or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 63c; Bleached, do., 57c; Whale Oil, cs., 52@57c.

BORAX.—Concentrated, 6@7c ½ lb.; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5@6c ½ lb.; No. 1, 4@5c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c ½ lb.

MOLYBDENUM.—Best, \$2.75 ½ lb.

CHROMIUM.—90% and over, ½ lb., 80c.

PHOSPHORUS.—American, ½ lb., 70c.

SILVER.—Chloride, ½ oz., 90c@1.00; nitrate, 55c.

RED LEAD.—500 lbs. and over at one purchase, ½ lb., 7c; less than 500 lbs., 7½c.

MANGANESE.—Per lb., \$2.75.

MAGNESIUM.—Pure, N. Y., \$1.60.

SODIUM.—Metal, ½ lb., 50c.

BISMUTH.—Subnitrate, ½ lb., \$2.10.

URANIUM.—Oxide, ½ lb., \$3.50.

MERCURY.—Bichloride, ½ lb., 77c.

TUNGSTEN.—Best, ½ lb., \$1.25.

FIRE BRICK.—Domestic, carloads ½ 1000, f. o. b., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skewback, \$30.00; circle, \$32.00.

FIRE CLAY.—Domestic, ½ ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, \$8.50.

## New Patents.

DEWEY, STRONG & Co.'s SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING FEBRUARY 21, 1905.

783,167.—CANNED FRUIT PROTECTION—T. J. Atkinson, San Francisco.  
783,009.—ELLIPSOGRAPH—H. C. Barnes, Oakland, Cal.  
783,239.—VEHICLE BRAKE—D. Berry, Fishrock, Cal.  
783,012.—SWIMMING DEVICE—Bredermann & Howald, San Francisco.  
783,094.—GAGE—H. D. Blakeslee, Upland, Cal.  
783,177.—HYDRAULIC LIFT—G. F. Cluff, Lodi, Cal.  
783,029.—FIREPROOF BUILDING—Depew & McCoy, San Francisco.  
783,271.—DRAFT EQUIPMENT—E. F. Domerwith, Davisville, Cal.  
783,034.—TRACTION WHEEL—F. Gerling, Portland, Or.  
783,035.—DRAFT APPLIANCE—F. A. Gerling, Portland, Or.  
783,195.—ELEVATOR—Harrison & Diel, Stockton, Cal.  
783,037.—ENGINE—N. P. J. Herby, Oakland, Cal.  
783,963.—CABINET—J. P. Hird, Redlands, Cal.  
783,969.—RATCHET SWIVEL—Kunny & Arundell, Los Angeles, Cal.  
783,055.—LUBRICATOR—P. Le Sueur, Calabases, Cal.  
783,066.—VEHICLE AXLE—P. Le Sueur, Calabases, Cal.  
783,404.—TAP—C. Lewin, San Francisco.  
783,211.—FLY PAPER HOLDER—J. O. Maddux, Bakersfield, Cal.  
783,067.—AIR DIFFUSER—T. Mahoney, San Francisco.  
783,063.—FIRE ESCAPE—D. G. McClay, Santa Ana, Cal.  
782,984.—NUT LOCK—McKinnon & Neely, Eleanon, Cal.  
783,218.—SAND BLAST—J. D. Murray, San Francisco.  
783,231.—CONCENTRATOR—O. B. Perry, San Francisco.  
783,222.—KILN—J. H. Regan, Tacoma, Wash.  
783,075.—WEIGHING MACHINE—E. H. Richardson, Ontario, Cal.  
783,226.—ARTIFICIAL LIMB—J. E. Seeley, Los Angeles, Cal.  
783,323.—ORE CRUSHER—F. P. Snow, Los Angeles, Cal.  
783,336.—ENGINE—C. R. Twitcheell, Dayton Heights, Cal.  
783,161.—BURNER—L. B. & H. B. Webster, Los Angeles, Cal.  
783,348.—INSULATOR—E. C. Wright, Portland, Or.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

ENGINE TRANSMISSION AND REVERSING DEVICES.—No. 783,037. Feb. 21, 1905. Nels P. J. Herby, Oakland, Cal., assigned to Gretchen Herby of same place. This invention relates to an apparatus for the convenient and easy transmission of power from a motor, means for varying the speed of the transmission, and means by which the motion may be reversed without the interposition of a number of gears or equivalent transmitting mechanism. The object of the invention is to provide for the reversing device and for changes of speed without the use of a multiplicity of expensive gears, with resultant loss of power by friction.

ELLIPSOGRAPH.—No. 783,009. Feb. 21, 1905. H. C. Barnes, Oakland, Cal., one third assigned to A. T. Spence, Alameda, Cal. This invention relates to an apparatus which is especially designed for the production of ellipses or similar curved outlines, such as are employed in the draftsman's profession. It consists of an ellipsograph having in combination a pair of pivoted supporting legs, a pivotally mounted third leg and means whereby it is restricted in adjustment in a plane bisecting the maximum angle formed by the supporting legs, and a slidable sleeve and marking point revolvable about said third leg, and other details of construction.

ELECTRIC AIR-DIFFUSING DEVICE.—No. 783,057. Feb. 21, 1905. T. Mahoney, San Francisco, Cal. This invention relates to a device which is especially intended for the diffusion of air or other fluids, either hot or cold. It consists in a combination and arrangement of mechanism whereby currents of air are caused to pass through a spirally disposed electrical heater and are directed to points where such a current is desired. The object of the invention is to provide an apparatus which is especially designed as a heater for apartments in cold weather and which may be equally well employed for cooling in warm weather.

FIREPROOF BUILDING CONSTRUCTION.—No. 783,029. Feb. 21, 1905. C. M. Depew and H. E. McCoy, San Francisco, Cal. This invention relates to improvements in fireproof building constructions, and particularly in flooring, ceiling and partition structures. Its object is to simplify, cheapen and lighten construction without in any way detracting from the stability and permanence of the finished structure. With this construction it is possible to whiten and finish the walls and ceilings the same day they are put up.

## Dividends.

The Bunker Hill & Sullivan M. & C. Co., dividend No. 89 of \$150,000, payable to-day; total paid since Jan. 1, 1905, \$300,000; total to date, \$2,571,000.

## Mine Drainage.

No problem with which the mining engineer has to deal is of greater importance than that of mine drainage. Where this can be accomplished by adits at reasonable cost it is done, but there are so many mines the workings of which are far below the drainage level of the country in which they are situated that the drainage question is often one of paramount importance. In the metal mining regions of the world, a few years ago, pumps were almost universally employed for this purpose, and the Cornish pump was generally preferred. This preference was so strong that types of Cornish pumps could be found performing service at mines under all sorts of conditions, from the little 4-inch jack head, handling the water of a shallow mine, up to the tremendous installations of the Comstock Lode, in Nevada, costing millions of dollars and successfully raising the hot water from those mines, but at great expense for power and repairs. In more recent years the Cornish type of pump has largely given place to reciprocating pumps, driven by steam, compressed air, or water. The pumps of this type possess the advantage of greatly reduced cost of installation, as compared with Cornish pumps of equal capacity, and flexibility of plant, which was not readily attainable with the Cornish system of mine drainage. Lower operating cost is also in their

favor. Still more recently electrically-driven pumps have proven economical in first cost, reasonably expensive in operating cost, while developing an efficiency which makes them compare favorably with other pumping systems. In the meantime bailing by means of skips of proper size and construction has grown steadily in favor, and this system now is

largely used in the coal mines of the Eastern United States, and is coming into more general use in the metal mines of the West. The power available for handling mine water is not always applied to the greatest advantage, and the method successfully applied at one mine may not be applicable to another where the conditions are different. The cost of

power, shaft room, and many other details, require consideration when figuring on drainage installation. There have been many experiments with the various types of pumps and other devices for handling mine water in the West, but there appears to be no unity of idea in regard to the best system for all conditions, and it is improbable that any single method of dealing with the water problem will find universally advantageous application. Each case must be treated in accordance with existing conditions.

In determining upon the system to be adopted in mine drainage by mechanical means, it should be remembered that the unknown and unknowable conditions which may be encountered are among the most important factors to be provided for. There are so many unforeseen contingencies which may arise that it is usually good business economy to provide a plant having considerably greater capacity than is required at the time of making the installation, particularly if it is the intention to go to a greater depth.

IN the consideration of the future development of mining and metallurgy, one can not help reviewing the past, and particularly the more recent past. There are few, who in the busy rush of to-day and in the preparation for to-morrow, stop to think for a moment what we were doing yesterday. The possibilities of the future can not be altogether gauged by the accomplishments of the past, but to some extent an idea of the future may be gained by such retrospection.

ONE of the most important acts of the fifty-eighth Congress, which has a bearing on the mining industry, was the passage of the act reserving two and a half million acres of timber land from entry by means of scrip, and prevents the selection of timber lands in lieu of lands which have been included within forest reserves, and hereafter the lands selected in lieu of such forest reserve lands must be untimbered lands. This act has been signed by the President and will save a vast area of timbered lands from wanton destruction by private owners, the most of whom are corporations. Over 2,000,000 acres of such timber lands have been taken up under the lieu lands act since its passage in 1897.

AN important consolidation of copper mining interests is reported as having been consummated at Bisbee, Ariz., in the merging under one management of the Calumet & Arizona, Calumet & Pittsburg, Lake Superior & Pittsburg and Pittsburg & Duluth mining companies. The object of consolidating these properties is to reduce the expense of copper production, by placing them all under one general management, and by greatly increasing the producing capacity of both mines and metallurgical works. The Calumet & Arizona is at present the only one of consolidation actually producing copper, but the ore reserves of the other properties are stated to be large.

## Small Electric Plants for Mines.

The transmission of electric power has done much to aid in the development of the mining industry of the West, particularly in the less accessible regions. It has cheapened the cost of power in most instances, both by direct application and through the medium of competition, with other kinds of power. The greater amount of electric power is supplied by large distributing companies, and the cost of power to those purchasing it from these companies is uniformly less than the cost of other kinds of power previously used. There are, however, many situations where mines can put in their own generating plant and still further reduce the cost of power. It is not suggested that a small plant will develop power at a less cost per unit than a large plant; but the larger power companies sell power at a considerable profit, and it is the saving to themselves of this profit that the individual mining companies may often accomplish by the installation of their own plant. The requisites are a constant supply of water and a situation where a pole line may be safely constructed and cheaply maintained. It is not absolutely necessary to success that a large head of water be available, if a large volume be obtainable. Under low head a large volume of water will generate cheap power, and in mountain regions a sufficient head to develop several hundred horse power may usually be obtained every few hundred yards. This idea conceives the employment of 2500 to 8000 cubic feet of water per minute, under a sufficient head to generate 200 H. P. to 500 H. P. The amount of power obtainable with a given quantity of water varies with the head. There are many factors to be taken into consideration in the contemplation of this problem, and the whole matter should be investigated carefully before any steps are taken to change existing conditions. In California, where are some of the largest electric plants in the world, which transmit great power at high voltages over a distance of hundreds of miles, the first installations were small individual concerns. The first to be installed was a small plant on the American river to supply light and power to the Dalmatia mine, in El Dorado county, and one of the first large electric installations by a single company in that State was that of the Standard Con. Company at Bodie, Mono county. The first has been discontinued for several years, as the mine was closed down. The second is still in successful operation. There are numerous other and successful private electric installations in California, as well as in other States of the West, and the surprise is that there are not more of them.

EFFORTS are constantly being made to reduce the cost of mining. For years it was the practice to carry all the ore from the levels to the surface on cages, or to dump the ore directly into skips from cars. These practices have been largely superseded by cutting loading pockets and chutes beneath the levels at shaft stations, and skips have in many places displaced cages. Trimming by men and animals has in many large mines been displaced by mechanical or motor haulage. In the operation of these methods, endless ropes or chains for mechanical haulage, and electric or compressed air motors are employed. More recently steam shovels, long in use in surface excavations, have been introduced into underground workings, it is said, with satisfactorily economic results. Still later came the automatic continuous loader, which carries the muck from the floor of the drift up into a car which, when full, is trammed to the station, its place being taken by another. The latest device in mining economy is a car provided with a steel shield which is run to the face to be blasted and the rock is thrown by the force of the blast directly into the waiting receptacle. At first thought the idea seems impracticable, but the defects, if any exist, will probably be remedied by the inventor who was bold enough to conceive such a scheme.

WITHIN the past week silver has taken a material drop both at home and abroad, though there is no apparent reason for such decline. Silver has become a commercial metal, like copper, and these sudden, though small, changes in prices may be expected, the price being regulated by the law of supply and demand, or by a speculative market.

## The True Basis of Value.

Large acreage is not a synonym of great value in mining possessions, though there are many, apparently, who incline to this belief, presumably on the theory that "if a little is good, more is better." This is largely the case in some localities, it is true, as for instance in many coal mining regions, and where such conditions obtain as are found in the Lake Superior copper region and on the Rand in South Africa. In these instances large areas of surface territory are underlain by mineral-bearing beds of great persistency, but of variable value, so that even in such cases, the outcome is somewhat speculative until proven. In the ordinary mining district, where fissures, zones and deposits are the typical forms of ore bodies found, a large area does not always signify unqualified success, as is abundantly proven by notable failures where there were hundreds of acres in the property. While this is a truism that cannot successfully be disputed, it does not signify that a mining property of small area may not prove a great bonanza. On the Comstock Lode at Virginia City, Nev., some of the smallest claims produced a great deal of money. At Randsburg, Cal., the Wedge mine, a small fraction, turned out many thousands of dollars, nearly all of which was profit. Instances might be multiplied indefinitely. The Goldfield camp in Nevada affords a score of examples showing that large values may come from a very small superficial area. Size is not the proper basis for estimate of the value of mining property, but the amount and value of ore actually in sight, together with the reasonable probabilities for the existence of more ore that has not been sufficiently exposed to render its measurement possible. The three measures of value adopted by careful and experienced engineers, "positive ore," "probable ore" and "possible ore," are the only safe means of arriving at definite information concerning the value of a mining property, and this can only be determined by close inspection and sampling of the mine and not by the measurement of the surface boundaries with a view to ascertaining the superficial area included in the property.

IN the middle of February last there were actually in the mines of the Rand, in South Africa, over 27,000 Chinese laborers, and more than 7500 were on the way, the most of whom have arrived at their destination by this time. Of the total number imported the mortality has been about 1.5 in a thousand, and it is not improbable that some of these would have died had they remained in their native land. In looking at these figures, and considering the statement that the Chinese are rapidly improving and becoming efficient workmen, it looks as though the importation of the Chinese had solved the labor problem on the Rand. The output of the mines of the Transvaal for 1904 is stated by the Transvaal Chamber of Mines to have been 3,779,621 fine ounces, the greatest ever made in one year since the opening of the mines. The number of men employed in December last was 134,105, of whom 15,962 were white men, over 97,000 natives and about 20,000 Chinese. Over \$15,000,000 worth of machinery was placed on the mines during the year, of which about two-thirds went to new mines. Among the recent installations is a hoist of the Whiting type having cylindro-conical drums with 20 feet maximum diameter diminishing to 12 feet at the smaller end. This machine is operated by steam, and is designed to hoist a load of 15 tons at a maximum speed of 4500 feet per minute from a depth of 4000 feet. Another installation to be made which is an innovation is found in one of the coal mines of the Transvaal, where the vein lies at an angle of 19°. The coal is to be sent to the surface on a belt conveyor, having a length of 525 feet between the centers of the reels. It is expected in the near future that the cost of power on the Rand will be reduced somewhat by the construction of large distributing electric plants.

THE term "mining expert" has of late years fallen into disrepute, for the reason that in this class there are many pretenders. The competent engineer is satisfied to be considered a mining engineer, leaving the title "expert" to those who profess more than they know and whose claim to being expert is often based on deception.

## CONCENTRATES.

FREE GOLD is insoluble in ferric salts in the absence of other oxidizing agents.

THE new Mexican import duty on dynamite went into effect on the 1st inst. It is \$210 a ton.

SMELTING of ores is as much a process of concentration as that of treating ores on vanners or jigs.

TO OPERATE crushing rolls to secure the best results requires a knowledge of the business gained by experience.

THE quicksilver contained in the tailings from pan mills usually exists, in part, at least, as calomel and is difficult to save.

GOLD frequently occurs in limestone and there are many authenticated instances. Several such occurrences are known in South Dakota and California.

A CHANGE in the grade of amalgamated plates in front of stamp batteries, from a steeper to a flatter grade, toward the lower end of the plate, is said to give satisfactory results in amalgamating fine gold.

THE velocity of flow of solution through a series of cyanide precipitating boxes may be changed by making some of the compartments longer than others. It is customary to make all compartments of the same size.

ALL PATENTS, agricultural as well as mineral, are supposed to contain the reservation of the right of lodes or veins, having their apex without the patented area, to follow the dip of the vein or lode beneath such patents.

SILVER was first discovered in the Calico district of San Bernardino county, Cal., by Loughry Silver, a prospector, who went into the Calico hills in 1881 from the Grapevine district, 12 miles west of Calico, and who discovered silver ore in Wall Street canyon.

PROSPECTORS' RULES which teach that a particular kind of metal or its ore should be sought only in a certain kind of rock are misleading in their tendency. The prospector must learn to avoid all such fallacious ideas and search carefully everywhere, overlooking nothing.

THE height of timber line varies in different localities. In Colorado it is in the vicinity of 11,000 feet. It is slightly higher in California, presumably due to climatic conditions. In Peru, South America, the timber line is little, if any, higher than in the United States, notwithstanding it is in the torrid zone.

THE occurrence of fluorite is not positive evidence of the presence of tellurides of gold or silver or tellurium in any form in an ore. Fluorite occurs abundantly in lead mines and elsewhere where no tellurium is known to exist. Fluorite is of common occurrence in the Cripple Creek district, Colo., and with the telluride ores of the Black Hills of South Dakota.

VANADINITE is vanadate of lead, and is composed of vanadium pentoxide and lead chloride. It contains about 19% vanadium pentoxide. This is variable with the vanadinite ores of Colorado, New Mexico and Arizona. Vanadium pentoxide is said to be worth \$1 per pound. Good specimens are probably more valuable for cabinet specimens than for any other purpose.

IN smelting it is desirable to have the blast even as to pressure and temperature and as dry as possible. Considerable variations in either of these factors give variable results in the running of the furnace. The hot blast has effected great economy in the operation of iron blast furnaces. It is estimated that every 100° of heat added to the temperature of the blast is the equivalent of 3% of the carbon burned at the tuyeres.

THE capacity of a stamp battery can be greatly increased by crushing through a rather coarse screen—12 or 16 mesh—and passing the pulp produced over an impact 30-mesh screen, the oversize being returned to the battery for finer crushing. This keeps a considerable amount of the material in circulation for a short time, but it will increase the capacity of stamps under given ordinary conditions from 50% to 100%.

MINOR CHILDREN born in the United States are citizens and may locate mining claims, and may participate in the location of claims to the same extent as adult citizens. Neither age nor sex is considered in defining who is a citizen, for the term includes men, women and children. If the minors are too young to act for themselves, others may make the location for them in their interest, but their names once having been placed on the notice they cannot be deprived of their rights in the property.

THERE are numerous places in the high mountains of Colorado where all mining supplies and provisions, and everything to be used in mining and to support life during winter, are taken to the mines the latter part of sum-

mer, and the men are imprisoned, as it were, after the first snow falls until the following spring. In some of these high mountain camps the rocks are frozen to a depth of several hundred feet, and at some of them the ground is thawed by burning cordwood against the face before blasting.

IT is difficult to give quotations on tungsten minerals. In 1902 there were produced in the United States 221 long tons of tungsten ores (principally wolframite), valued at \$38,600. In the same year 82,000 pounds of tungsten were produced (presumably from the ore referred to), worth \$50,000, or about 60 cents per pound. Scheelite is an ore of tungsten. Its principal use is in the manufacture of certain grades of steel. The market can easily be overstocked by too heavy a production, as the demand for this and similar minerals is limited.

THE cost of any particular mining operation cannot always easily be predetermined, owing to the possibility of unforeseen changes in the ground to be passed through. Hard rock unexpectedly becomes soft, and vice versa. One portion may require timbering, another may not need it. The damage from blasting in some cases is unavoidably heavy, and the uncertainty which surrounds mining mechanics generally makes close estimates impossible. Contractors base their judgment on the average conditions under similar circumstances.

THE trials of the millman are often due not so much to his lack of ability and experience as to the disregard of the owners (individuals or company) to the requirements of the case. They argue that they have built and thoroughly equipped the mill with what they are assured was modern machinery. This may be true, but at the same time the machinery may not be suited to the ore; yet of this the millman cannot convince them. There are others, fortunately, who have the business sense to appreciate the disadvantages of improper machinery, and are willing to make the necessary changes.

THE report of the "California Debris Commissioner" may be obtained by addressing that official, W. W. Waggoner, Nevada City, Cal. The "Geology of the Perry Basin, Southeastern Maine"—Professional Paper No. 35 of the United States Geological Survey—together with other bulletins and professional papers, may be obtained by applying to the Director of the United States Geological Survey, Washington, D. C. Bulletin No. 35 of the California State Mining Bureau may be obtained by addressing the State Mineralogist of California, L. E. Aubury, San Francisco, Cal. No cost. Postage 2 cents.

ANGLESITE is lead sulphate. It occurs sparingly with other lead ores, and is the result of oxidation of lead sulphide (galena). Its most common occurrence is as a light gray ash-colored soft mineral of noticeably high specific gravity. It often shows a peculiar tracing of right angled lines, the remains of the cubic crystallization of the galena. The masses of ore often contain unaltered galena. Anglesite also occurs white, or tinged with yellow, green or blue, due to oxides of other metals. Minium is native red lead (lead oxide). It is of comparatively rare occurrence in large quantity, but is found in a few places in small amounts. Specimens were found in the oxidized zone at Leadville, Colo.

WHAT is known as the Bruckner cylinder is a type of rotary roasting furnace resting horizontally on rollers, and revolving between a fire box at one end and a flue leading to a dust chamber and stack at the other. The furnace is provided with manholes for the reception and discharge of ore charges. The cylinder is caused to revolve slowly, the smaller ones by means of friction rollers and the larger ones by gears, which engage a spur gear encircling the cylinder. The fire box is either stationary or movable. With the movable fire box one box may serve two or more furnaces in one battery. By this arrangement a fire box, after thoroughly igniting the sulphur in a charge in one furnace, may be moved along to the next, and this fired in turn. Later, when necessary, the fire box may be again brought in front of any particular furnace. In the Bruckner furnace ore may be treated in charges of several tons, and the roasting continued as long as desired, as it is not arranged to make a continuous discharge like the White-Howell furnace. At the Anaconda works there are 252 Bruckner cylinders. The furnaces may be run at any desired speed.

WHERE a mining location was made Jan. 1, 1903, and some party, unknown to the locator, performed work on the claim in March, 1904, this work, performed by the trespasser, cannot be claimed by the actual proprietor of the claim. Assessment work must be done by the owner or at his instance. Work done by a trespasser, even though paid for afterward by the owner, cannot be credited to assessment work. (Little Gunnell M. Co. v. Kimber, 1 Morr. Min. Rep. 536; Neshitt v. De Lamar's Nevada G. M. Co., 24 Nev. 273.) If the claim has not already been relocated by another for failure to comply with the law, the original locator may begin assessment work for 1905 and having done \$100 worth, may hold the claim until Jan. 1, 1907, when, if he has done no more work, it again becomes subject to relocation. There is no need to relocate, for the law does not permit a claim holder to profit by his own negligence (failure to do the

necessary assessment work) and thus hold the claim. The original locator's claim holds good without work until some other party intervenes, when, if the first locator has failed to comply with the law, his title to the claim is lost. In the case of a claim located Jan. 1, 1903, and pocket hunters did the necessary work by permission of the owners, in both 1903 and 1904, this work would stand for assessment on the claim on which it was done, but not for both claims, unless the claims adjoined and it could be clearly shown that both claims were benefited by the work done on one.

TUNNEL RIGHT CLAIMS usually encounter many legal difficulties if taken up in mineral districts in which there have previously been made numerous locations. A tunnel right which is the first to claim the lodes along its line is not altogether free from the possibility of lawsuits. The section of the Revised Statutes which defines tunnel site locations is as follows: "Where a tunnel is run for the development of a vein or lode, or for the discovery of mines, the owners of such tunnel shall have the right of possession of all veins or lodes within 3000 feet of the face (meaning mouth or portal) of such tunnel on the line thereof, not previously known to exist, discovered in such tunnel, to the same extent as if discovered on the surface; and locations on the line of such tunnel of veins or lodes not appearing on the surface, made by other parties after the commencement of the tunnel, and while the same is being prosecuted with reasonable diligence, shall be invalid; but failure to prosecute the work on the tunnel for six months shall be considered as an abandonment of the right to all undiscovered veins on the line of such tunnel." By the words "the line thereof," as used in the above section, the United States Land Office decided that it referred to the full width of the tunnel, and no more. A lode discovered in the tunnel, not previously known, entitles the discoverer to 1500 feet on the vein or lode so discovered, and he may take the entire 1500 feet on one side or the other, as he pleases, or he may take a portion of the 1500 feet on one side and the remainder of it on the other.

ORE deposits, though for the most part of relatively recent age, as compared with the earlier geological formations of the earth's crust, occur in rocks of all ages from Archean to Tertiary and even recent, though the age of the ore deposit itself may be much later than the rock in which it occurs. Thus ore deposits of undoubted Tertiary age are found in Archean and Cambrian rocks. The gold-bearing ore shoots of the Homestake in the Black Hills of South Dakota are found in Archean rocks, and are also, in part, of Archean age, though supposed to have been enriched by the intrusion of igneous rocks about the close of the Cretaceous. The copper deposits of the United Verde mine at Jerome, Arizona, are in Archean rocks, but the age of the ore deposit is speculative. The lead-silver deposits of Leadville occur in limestone of Carboniferous age, but the ore deposits were formed long after the deposit of the formation. The gold mines of the California gold belt are mostly in Jurassic rocks (Mariposa beds), but those of the East Lode are in much older rocks, known as the Calaveras formation (Paleozoic). The formation of the ore bodies occurred not earlier probably than the close of the Cretaceous. Many of the most important ore bodies of the West are as late as Tertiary and occur in Tertiary rocks. Age is no indication of value or volume of ore bodies. There are comparatively few ore bodies of an age contemporaneous with the rocks in which they occur, though such do exist. Such, for instance, are some bodies of limonite iron ore; the borax deposit (colemanite) at Borate, Cal.; certain auriferous conglomerates, etc.

ALTHOUGH canvas plants are of great service under ordinary conditions, by the proper arrangement of hydraulic classifiers and mechanical concentrators the canvas table may be rendered almost useless. The object of the canvas table is to collect the slimes escaping the various types of concentrating machines, but the fact that at least one experienced concentrator man has successfully cleaned slimes from canvas tables on mechanical concentrators demonstrates that these finely divided sulphides may be saved on machines if the proper methods be employed in classifying the pulp before sending it to the machines. This is due to the fact that both coarse and fine particles of sulphide cannot be saved on a single machine without first, in some measure, effecting a segregation of the particles to be treated into material of approximately equal size but differing specific gravity. In this regard classifying must not be confused with sizing. Classifying is accomplished by means of pointed boxes, cones, etc., and the principle of the operation is based upon the unequal tendency of particles of variable size and having different specific gravities, to settle unequally in a medium—the heavier particles settling more quickly than the lighter. This enables the operator to draw off at the upper part of the box the lighter particles, the coarser and heavier being discharged at the bottom. The process may be carried still further by also employing sizing screens, which effect a separation of the grains into those of approximately equal size but of varying gravity. The process may be carried to any desired extent by a series of cone-shaped settlers, as has been demonstrated by F. W. Sherman at Park City, Utah, a description of whose plant and its operation appeared in the issue of the MINING AND SCIENTIFIC PRESS of March 26, 1904.

## The Goldfield District, Nevada.\*

Written for the MINING AND SCIENTIFIC PRESS by M. D. DRAPER.

As many persons have confused, or generalized the new mining camp of Goldfield, Nev., with the new discoveries—the new gold fields of southwestern Nevada—it will be well to differentiate these at the outset of this article.

The Goldfield district proper, of which the town of Goldfield is the commercial center, consists of a known ore-bearing area of about 10 miles long by about 5 miles wide. To those who are familiar with the Cripple Creek district in Colorado, it may be said that the Goldfield district is somewhat similar, the smaller towns, such as Columbia, Jumbo and Diamondfield, occupying positions something like the towns of Victor, Anaconda, Independence and Altman in the Cripple Creek district.

Goldfield lies about 30 miles south of the now well-known mining camp, Tonopah, which is the present terminus of the railroad. Contracts are now being let for grading for the continuance of the road into Goldfield in the spring.

The engravings accompanying this article both on this page and on the front page are from "Greater Nevada," by courtesy of the Reno Chamber of Commerce.

The discoveries of the district seem to have marked the beginning of a series of the most extraordinary finds farther south that have been made in mining in many years, and the deserts of southern Nevada, so long silent and deserted, are now receiving a thorough investigation in every nook and cranny.

Goldfield, proper, continues to expand with new discoveries, and a production which has already been phenomenal promises to be still further greatly increased.

We are accustomed to hear in the ordinary new camp of large assays and rich ore; but we are much less accustomed to seeing returns from thousands of tons of marketed ore which averages \$300 per ton for the entire output, though this is the case in Goldfield.

The inception of the district began with discoveries of ore in the spring of 1903. After an interval of spasmodic prospecting, followed by some little definite development, the January mine began to ship in 1904, followed later by the Combination, and still later by the Jumbo and the Florence.

The four mines named decided the future of the district, as they continued to ship quantities of very high-grade ore, thereby attracting the attention of capital. This money has been put to such good use that at present Goldfield may be said to have at least fifteen shipping mines, the most prominent of these being the January, Jumbo, Florence, Combination, Sandstorm, Kendall, Quartzite, Tonopah Club, Black Butte, Lone Star, St. Ives, Velvet and Cimarron.

Besides those named, there are probably thirty other mines containing quantities of ore running less than \$50 per ton; but few, if any, of the mines ship any grade less than \$200 per ton, as the hauling and freight is necessarily high at present. Hauling, freight, treatment and incidentals bring up the total cost to figure between \$35 and \$50 per ton.

To all practical intent and purpose the camp is one year old. During the year 1904 the total production was about \$2,750,000, or an average grade of ore of \$300 per ton.

Like all new camps, Goldfield has its disadvantages, chief among which is the high cost of supplies, owing to heavy freight charges. The following brief summary will give some idea as to present conditions in Goldfield:

Approximate population of Goldfield (town), 7000; approximate population of the district, 10,000; location, in rolling hills or somewhat rocky ridges, bordering sandy deserts in southwestern Nevada, 31 miles south of Tonopah and about 45 miles from the California line; altitude, 5600 feet; climate, very mild, with occasional snow flurries in winter, hot in summer with cool nights; telegraph and telephone lines to outside points; automobile and stage lines between Tonopah and Goldfield; four banks in operation; electric light plant running; six to eight custom mills building; water in the district, and power being brought in from Bishop, Cal.; water for domestic purposes abundant and pure; water for milling purposes at present scarce, but being rapidly developed; population living in tents or adobe houses; numerous frame buildings in the course of erection; numbers of restaurants, lodging houses, saloons, groceries and hardware stores.

Transportation into Goldfield is as follows:

From Reno, S. P. R. Tonopah, about 250 miles, fare, \$17.50; stage fare Tonopah-Goldfield, 30 miles, 50 pounds baggage, \$4; automobile fare

Tonopah-Goldfield, 30 miles, 20 pounds baggage, \$6; all excess baggage, 2 cents per pound.

Most of the mines have gasoline hoists, though there are some steam hoists, using wood for fuel. Groceries and other general commodities are about 30% higher than outside points. Camp wages are \$4 for eight hours' work.

**GEOLOGY.**—A period of great volcanic activity, during which a number of successive flows of andesite and rhyolite from various vents occurred, was followed by fissuring of these rocks and the subsequent deposition in and around these open fissures of immense quantities of silica. In fact, in almost every part of the district the original porphyries now contain more silica than at first. Naturally, there has been great metamorphism. Former normal andesites are now silicified andesitic breccias, and both they and the rhyolites, especially along the lines of fissuring, are often changed for hundreds of feet to what, for lack of a better term, may be called quartzite, inasmuch as the rock, both in composition and texture, resembles quartzite. It will be understood that in the strict sense of the term this rock is not quartzite, and that the name is employed here only for distinguishing purposes. The deposition of this silica was no doubt accompanied by small amounts of the ordinary ore-bearing materials, such as pyrite (but with no appreciable amounts of the precious metals), as almost any of the dikes will show its occurrence very finely distributed throughout the rock.

Following these phenomena was another period of dynamic movement, causing a second fracturing and fissuring of both the country rock and the quartzite, for we find the quartzite throughout the district shattered, brecciated and re cemented, which with all the accompanying conditions indicate that at this time the secondary fissures were filled with ore. That this really was a secondary fracturing is proven by the fact that

In the central part of the district it is common to find large areas of greatly altered porphyries, an indiscriminate mixture of kaolin, iron oxide, talc and gypsum, being the results of alteration and decomposition. In such areas more than ordinarily well defined, and separated streaks of the vein constituents, indicate the one-time existence of well defined walls. This condition prevails over considerable distances and actual walls are sometimes met with. There are also ore deposits of value in these greatly decomposed areas, but as yet none have been found of the extent or value of the deposits occurring in or near the quartzite dikes previously mentioned.

Still later than the phenomena mentioned a comparatively thin sheet of basalt, from near-by vents, spread over probably the whole district, but subsequent erosion has removed the greater part of it, its occurrence being now evidenced by an occasional lava-capped butte, within the area, or by the mesas, similarly covered, at some distance away from the mineral bearing areas.

The occurrence of a very small area of sedimentary rock at one place in the district has led to much

Silver Bell No. 1, Goldfield, Nev.

Ray & O'Brien Mine, Goldfield, Nev.

Velvet Shaft, Goldfield, Nev.

the ore-bearing veins, as they are now, run in various directions through the massive quartzite dikes, as well as through less siliceous country rock.

As might have been supposed, however, the ore-bearing veins occur in close proximity to, if not within the actual body of, the original massive "quartzite dikes" often, in fact, in one contact or the other of the dike and country rock; the secondary fracturing occurring along lines of weakness determined, usually, by the course of the dikes.

There are a number of cases where ore has been found where the vein walls are well defined, but as a rule such is not the case, the ore occurring in more or less irregular bodies, usually along the same general strike, and sometimes with stringers of feeders leading from one to another.

It is altogether probable that this secondary fracturing has been caused by the uplifting of the underlying Archæan rock, as we find it in several places occurring in more or less rounded bosses, where it has lifted the later volcanic rocks in dome-shaped masses.

There are other occurrences of this rock as isolated islands in the general porphyry mass. For all practical purposes the rock may be called granite, though some engineers have preferred to further differentiate it, suggesting the term alaskite (aplite), owing to its relatively small amount of mica and other characteristics.

Rhyolites, andesites and hornblende-andesites occur in large bodies with no definite relation to each other—the rhyolites sometimes apparently shading imperceptibly into andesite. It is noteworthy here that there are no known deposits of ore occurring in the hornblende-andesites. The more acid of the andesites, however, often contain ore deposits, and generally have more or less well-defined phenocrysts of feldspar.

diverse opinion. On the Tonopah Club mine there is a deposit of what appears to be shale at least several hundred feet in length, which is all more or less gold bearing. It occurs at a contact between andesite and rhyolite (see illustration) on the one side, and a basic hornblende-andesite on the other. It varies in width from 3 to 20 feet, seeming to compose, together with gypsum, talc, brecciated porphyries and quartz, a contact vein of large width. In order to conform to a theory advanced by some, namely, that the quartzite dikes were due to the replacement and silicification, in situ, of limestone beds, it was suggested that similarly the gypsum here was due to a metamorphism of lime overlying the shale to calcium sulphate either by the medium of decomposing sulphides, or by solfataric waters.

That this theory is untenable is shown by the fact that the quartzite dikes occur everywhere throughout the district at places where it is impossible to conceive any previously existing sedimentary rocks, and it is my belief that the gypsum is merely another phase of deposition as vein material, as it, like the dikes, occurs everywhere throughout the district. The occurrence of calcite itself (cited similarly as a proof of the former presence of limestone) in small quantities may be similarly explained. The shale, however, being a true sedimentary rock is more difficult to account for. It is reasonable to believe that it is of minor and local occurrence, and is probably due to a lake shore deposit, or something similar, at a period contemporaneous with or intervening between the porphyry flows, and that it has nothing to do with the sedimentary rocks lying farther to the west, near the Montezuma district, which is the nearest occurrence of importance of the sedimentaries, and which lies several miles away.

Calcite, it is true, occurs occasionally, but always as vein filling, and is therefore probably due to sol-

\*See illustrations on front page.

fatatic action and not sedimentary deposit. With the one exception noted, therefore, it is considered that there is no sedimentary rock within the Goldfield district proper.

Taken as a whole, the ore bodies of the district may be said to be somewhat erratic. They occur in lenticular or irregular detached form, sometimes having stringers leading from one to another, more often without any connecting link. They nearly always occur along the same general strike and, taken as a whole, they may be considered almost as continuous, as much so as high-grade ore ordinarily occurs in a fissure vein. For the reason that we have the case of ore bodies without the ordinary vein walls they are considered more erratic than usual. Viewed in the commercial sense this feature is no more detrimental than any one of the ordinary disadvantages conditions that are found in any camp, namely, wet mines, running ground, etc. In comparison, the extraordinary grade of the ore will more than compensate for any such objectionable feature. The accompanying sketches illustrate the

tents not exceeding an average of 4%. The latter consists almost altogether of pyrite in a very finely divided condition. Minute amounts of gray copper occur sometimes, and occasionally tellurides. The occurrence of the latter element is mentioned by J. E. Spurr in an analysis made by the United States Geological Survey, and has been noted in the Quartzite mine. Fluorite and gypsum also occur in small amounts. The general direction of the veins is north and south; there are a number of veins running at angles with the main system, but they are usually of less importance. In the Diamondfield section, however, the main vein system runs in a more general east and west direction.

One of the most important characteristics of the district is the high grade of the ore. As before stated, a total of about \$3,000,000 has been marketed from the camp in the past year, at an average of about \$300 per ton. This tonnage has been taken out with extremely primitive facilities, and at every possible disadvantage in operation. In the extraction of this grade of ore some interesting and pic-

hoisted, and an art gallery would not be sufficient to accommodate the "picture" assays made on selected specimens.

In the development and extraction of the high-grade ore a considerable quantity of low-grade ore has been taken out or thrown on the dumps, and several mines that have not as yet shipped at all have opened up large bodies of ore running from \$12 to \$75 per ton, which will, of course, be treated later. Among the latter may be noted such mines as the Tonopah Club, Black Butte and Red Top.

Various milling plants for the treatment of the low-grade ore are either contemplated or in different stages of construction. Owing to the limited amount of oxidized ores and the fineness of the sulphides, the amalgamation or concentration of the ores will probably have to be supplemented by slime plants behind the concentrators or cyanidation of the tailings.

Though the country is pre-eminently a dry desert, development of water for milling purposes is going on at present and there will be little difficulty in obtaining any required amount. Fortunately the ground stands well in most of the mines, requiring little timbering. Lumber costs \$70 per 1000 feet. As it is, 6x6-inch timbers are used for stulls, and plank for lagging.

This district may be said to be covered with locations, but property owners are in most cases willing to lease undeveloped ground at royalties varying from 5% to 20%; in truth, the district has been developed by lessees, a number of leases having expired January 1, 1905.

It is said that the town of Goldfield is completely

character of mineralization and vein formation in the Goldfield district.

The four main producing mines of the camp, the Jumbo, Combination, Florence and January, are all below the oxidized zone, the change from the oxidized to the sulphide ores occurring at a depth of about 150 feet. In every case the change does not materially affect the values of the ore, a most favorable feature for the camp. In the case of the Kendall and Sandstorm, sulphides were encountered on the surface. The former mine has a remarkable record, a total of \$100,000 having been produced from a 10-foot hole and one or two small surface trenches. The management of this mine has installed a steam hoisting plant and is beginning a crosscut for the vein from the 100-foot level.

The four mines above mentioned have all struck water in small amounts—a fact that is looked upon with favor because of the exceeding dryness of the country. The Combination shaft, at a depth of 350 feet, is the deepest in the camp.

Much of the ore of the district has the same character, usually highly siliceous, or with varying amounts of mineralized porphyry, the sulphide con-

ditions have been met with. On the Sandstorm and Kendall, for instance, the sagebrush is pulled up and thrown to one side and the soil swept up from the bedrock, screened, sacked and shipped, netting for soil, roots, quartz, etc., \$250 per ton; this is the nearest to shipping scenery that comes within my knowledge.

On the Jumbo, on one lease, as it was about to expire, men were taken from \$500 ore and put to work on a lower level extracting \$1000 ore. On another lease a miner drilling an "upper" had a small sample sack tied underneath the collar of the hole with which he saved the drillings for shipment, deriving from this source several dollars to the pound. On the Loftus-Davis lease, on the Sandstorm, ore was at one time sacked which was estimated to be worth between \$1 and \$2 per ounce; the fine gold could be seen running from the shovel point as the ore was being sacked.

On one of the Jumbo leases the owners were offered \$25,000 for a one-sixth interest in a lease when it had five months to run; the offer, it was stated, was promptly refused. Many instances are on record in the camp where ore worth \$1000 per sack was

equipped with the usual adjuncts of a mining camp. The promoter with glittering generalities is here, as is also the engineer of abstruse technicalities. The freak process man with a 110% extraction process has located already, and the curious sightseer travels side by side with the conservative investor. Fraction hunters vie with lot jumpers in activity, and the burro and the automobile travel the same road.

More important than all the foregoing is the fact that ore in large quantities, and of a very high grade, exists or has been shipped from many different places, and that the character of the ore and its amount assures a large and permanent camp in Goldfield.

Much of the inside territory has been incorporated into the holdings of various companies, and likely much of this will be developed later by lessees. For the present, it may be said that, viewed from previous developments, the production during the present year will be very large. New discoveries are of frequent occurrence, and the whole area has been prospected, but in a desultory manner, and to all intents it may be said to have been barely scratched.

Goldfield is not at present a favorable location for

the working miner. Many companies are in the first stages of incorporation, or are raising money, and the working mines have so little development that, considering the population of the district (about 8000), the number of actual working miners is small. Later, say in a year from now, the miner's opportunities will improve.

On the other hand, the country is probably one of the best in the United States for the practical and experienced prospector. By this, I do not mean the territory immediately surrounding Goldfield, but in the vicinity of the new discoveries recently made farther south.

Following the discovery of ore in Goldfield as prospectors gradually made their way into the surrounding country, it was found that practically all the area south of Goldfield was mineral bearing, and in the fall of 1904 very high-grade ore was discovered in what is now called Bullfrog district. This discovery resulted in a rush to the new locality and several other mines were opened up which presented an extremely favorable showing on the surface, ore showing free gold being broken from surface croppings, and assays showing low-grade ore—\$15 to \$20 per ton—across large widths, varying from 20 to 80 feet, and some as high as 200 feet. At least five mines in this locality, which is about 70 miles south of Goldfield, show high-grade ore, and a shipment from one of them ran about \$1700 per ton.

Later on another district—Kawich, about 75 miles east of Goldfield—was discovered, where high-grade ore was similarly found, and within the last three weeks high-grade ore was discovered at Lida, about 30 miles south.

Taken as a whole, the southern country is easily prospected, the topography consisting of sandy deserts, with low mountain ranges. The wash is seldom deep and the ledges, which are large, usually outcrop. Water is scarce.

In the Goldfield district present charges on ore—for hauling, freight and treatment—amount to about \$35 per ton, though with the advent of the railroad these charges will probably be reduced somewhat. Charges on ore from the other districts named will, of course, be higher, but mills are already contemplated for the Bullfrog and other districts.

Recently some unfortunate and very sensational newspaper articles were published relative to sickness in Goldfield. These articles were sent out entirely without foundation and deserve no more than passing mention.

As a whole, no mining camp discovered in recent years in the United States has equaled Goldfield. It is difficult to predict the future, but with the present knowledge, which shows the ore bodies to maintain their values with increased depth, and in the light of several recent discoveries, it seems safe to say that its production in 1905 will be between \$5,000,000 and \$10,000,000. Certainly we may be positive that it will be greater than in 1904, and this alone will prove Goldfield one of the highest order of the mining camps of the world.

Fig. 1 shows the character of ore deposit of most common occurrence—a zone of shearing and silicification, with independent veins in the vicinity of fissure type.

Fig. 2 shows the irregular form of deposits in the neighborhood of zones of fracture and shearing, and also to veins of definite boundaries, as on the left of the sketch. The dotted surface indicates soil which was screened and shipped, worth \$200 per ton. In the portions indicated by black, irregular-shaped ore bodies the quartz sometimes runs up to \$1000 per ton.

Fig. 3 indicates a less common ore occurrence at Goldfield. Here ore occurs independent of the dike, though in direct line with it and probably influenced by it.

Fig. 4 shows a defined vein crossing the strike of a sheared zone, with ore at the intersection. The portions of the vein at some distance from the intersection consists of soft kaolinized feldspar and other vein materials.

Fig. 5 shows ore occurrence at the Tonopah Club mine, Goldfield, Nev., at contact of rhyolite and hornblende andesite.

Fig. 6 represents a typical ore occurrence in Goldfield district and shows several zones of crushing and silicification and the formation of high-grade ore shoots in the silicified zone.

Fig. 7 presents a vertical cross-section at Goldfield, Nev., showing contact vein on the right, an irregular deposit in the center, and a defined fissure vein with good walls on the left of the sketch.

The heavy steam stamp has been effectively used in crushing millions of tons of ore before concentration during the past thirty years or more. Its most extensive application has been at the Lake Superior copper mines. More recently it has been employed in a similar capacity on the sulphide copper ores of Butte district, Mont. The capacity of these steam stamps has been increased from time to time from less than 100 tons per day to over 500 tons in twenty-four hours. Although this type of crushing machine has found great favor in the copper region, they are not in use, as far as known, in crushing gold ores prior to amalgamation.

## Relative Merits of Wet and Dry Crushing in Cyanidation.\*

By PAUL DANCKWARDT.

The question of stamps versus dry rolls would be a simple one if we had only one kind of ore in the Black Hills. But as this is not the condition here, and as, therefore, the character of the ore in each case is to be considered, the deciding point for the selection of the grinding process, the question resolves itself into that: What kind of machinery is the one that will give the best end result, or, in other words, or, by the use of which grinding process can we make the most money out of a given ore? Obviously it is just the same, whether the power required for the process is high or low, or whether the repairs are one way or the other, if the balance of all our accounts in any way of procedure is the most favorable one from the standpoint of the investor.

Of course, I will not say that the expense of grinding is a very unimportant function of the process employed, but that it is only a function, that it does not mean all of it or might be considered the deciding factor. Without going into details, I will endeavor to present an outline of the leading points which determine the selection of the proper kind of machinery to be used at a mill. But it may be stated that nothing is perfect and that everything, the machinery as well as the metallurgical processes, are continually in a stage of evolution, which state of affairs renders a correct answer extremely difficult. It is an easy task only for him whose creed never can be changed and to whom science is nothing but a rule of three.

The most important point is the degree of fineness required for a reasonable percentage of extraction. In this respect we find a great variety of ores in the Black Hills, of which the two extremes are represented by those of the Ragged Top district and some ores of Yellow creek on one side, and the Bald mountain ores on the other side. Between them are a good many ores, for which it is hard to fix correctly, in advance, which kind of machinery will be the best. For the first class of ores, those of Ragged Top and some of Yellow creek, rolls are without doubt rightly favored, for they require only a moderate degree of disintegration and generally no drying. No dust can cause any loss of values, or a high expense for oil and repairs, and the mills, therefore, can avail themselves of the advantage which rolls offer, that of cheap power. In reality in such a case the advantage which rolls offer is more apparent than actual, as anybody must agree to, if he considers that the grinding of the same amount of material to a finer mesh would actually call for a greater outlay of power and first cost of installation, which two factors form the proper basis of comparison, if otherwise the same conditions are prevalent.

The Bald Mountain ores, however, generally demand a high degree of fineness. In order to be able to perform this successfully by means of dry rolls it has been found necessary to dry the ores preparatory to the grinding, which not only causes extra expense for fuel, power, labor and repairs, but is also the cause of an appreciable amount of loss of values in the form of dust, and not at all must be disregarded the bad effect upon the health and efficiency of the workmen in attending and repairing machinery, a greater loss of time, and the more expensive way of charging the tanks. It has, however, one advantage, as justly stated by the inquirer, viz., that dust can be charged together with the coarse ores into the tanks, providing the ore does not require more than a certain degree of fineness. If, for instance, at the Golden Reward mill, the ore was ground finer than that delivered by an inclined screen of 6 mesh, No. 16 wire, we experienced not only a considerable falling off of the efficiency of the rolls, but also a lower extraction and an irregular leaching of the ore in the vats. The limits of this phenomenon will, of course, vary with the character of the rock, the percentage of fines, gauge, etc. Here, when such finer grinding is desirable on account of the character of the ore, is to be found the real weak point of the rolls. I believe to be right in making the statement, that then the rolls must be discarded altogether, as a subsequent separation of fines and coarse would mean an amalgamation of the weak points of both the dry and wet way, without having the advantages of any of the methods. Then we would, indeed, better start in the wet way right in the beginning. Whether this is done by means of stamps, wet rolls or Chilian mills, is a special question.

While I hope to have made clear where wet crushing is almost imperative, I will pursue the line of thought further by entering a subject still undecided here in the Hills—the question of very fine grinding. There are very strong advocates of such a plan for certain ores, and my own experience with a great variety of ores leads me to believe that they are justified in a good many cases, and that in this direction certainly more hope for improvement exists than in the idea of adding the roasting process to the present dry crushing process. This latter process would involve, if the success shall be only nearly general, likewise a preceding finer grinding which

would cause a loss in value during the following stage of roasting, that when added to the additional cost of both roasting and finer grinding would bar its introduction on a commercial scale. On the other hand, though a good many ores will show only slightly increased extraction by fine grinding alone they will with few exceptions yield enough additional value to pay for the extra expense, but for a great many ores, among them just the richer class, very fine grinding would offer the only means of profitable treatment by cyanide.

If we look at this as a fact, wet crushing would be the proper way of treatment generally and this would mean the necessity of installing wet grinding machinery (excepting special cases mentioned.) However, as I stated above, I would prefer Chilian mills to stamps, as they produce already a large amount of fines, and the regrinding in tube mills of the sands. Wet rolls, though they have the same advantage of cheap power as Chilian mills, are not so much to be recommended because they make a very uniform product and few slimes which are desired in our case. It may be granted that there exists a question of the proper treatment of slimes, which themselves are of a valuable nature, but this problem has lately been broached by a number of firms in and outside the Hills and will be solved, as the necessity exists. The American engineers have overcome greater obstacles than this before, and as long as the conditions promise to pay for the work and intelligence applied, nobody need entertain any doubt of the final outcome. This once obtained, the wet process would stand triumphant, while so far the two processes come out about even, as at present the mills using the wet process suffer a considerable loss in both dissolved gold and cyanide with the tailings when discharged.

In my opinion it is not so much a question of stamps or dry rolls, but that of wet or dry crushing and grinding based upon the character of the special ore to be handled, and that this is to be determined correctly before putting a plant up on the single point of cheap or inexpensive grinding machinery, and I have herein, therefore, treated the subject from this standpoint abstracting from all detailed costs, which mean nothing if not the possibilities of improved methods are expressed in figures likewise. This is not possible at present, but it may be stated that these possibilities of the metallurgical field are almost as great and wide as the Black Hills themselves.

## Smelter for Siliceous Sulphide Ores.

There are few questions in metallurgy and mining perhaps that have attracted more attention and to which more study and experiment have been given than that of smelting of sulphides, utilizing the fuel elements in the ores to smelt themselves.

Some extensive demonstration of this work is reported as having been done on the mines of the Lustre Mining Co., near El Oro, Mexico, in a smelter designed by John W. MacDonald of Pittsburgh and installed in 1901, which the Lustre Company state carried from the start all the cost of development, treatment, etc., and a surplus besides.

The MacDonald smelter for hot blast matte smelting is designed along new lines for heating the air for hot blast. The design is to utilize the waste heat from smelter to stack in raising the temperature of the air to 500° to 700°, and in a smelter of special design and proportions; also a different manner of handling the ore feed.

The company owns a patent on a converter of new design which has not yet been perfected, but which they say embodies the principles now used in converting matte, but which does the work in a small outfit located alongside the smelter, and which will take the molten matte direct from the forehearth to converter, that the smelter in operation, with converter attached, is designed to treat the raw sulphide ores from the mine direct to smelter without any preliminary treatment, and smelt to matte and convert to bullion in one continuous operation.

There are hundreds of mining companies with large bodies of siliceous sulphide ores which such a smelter would make valuable. The company manager states that he has several contracts under consideration, and that some of these smelters will be in operation as soon as its merit is fully recognized. The manager, C. W. Munson, Toledo, Ohio, would be pleased to give further information.

## Cyaniding Black Sand.

TO THE EDITOR:—I notice that in reply to a correspondent you say you see no reason why black sand should not be cyanided. Will you allow me to say that the gold in it can be cyanided, but owing to iron being dissolved, it cannot be precipitated upon zinc shavings, as the iron covers the Zn and prevents the displacement of Zn with Au. If you know of any one who can cyanide black sand I shall be pleased to show them where they can procure millions of tons of it, and in one place where I tried to cyanide it there are 280,000 tons containing \$4.50 per ton. This sand is cemented by action of sea water, but is quite porous and very easily broken up.

Salmo, B. C.

\*Trans. Black Hills Min. Assn.

Method of Keeping "Stope Books" in the Butte District, Montana.\*

Written by C. E. MORRISON, C. E.

In mining, as in any business enterprise, systematized records are essential to safeguard against error, and in no part of the work are they more important than in that which deals with the actual extraction of mineral.

Such records might be divided into those referring to the geological features alone, and those which relate to the general characteristics of the ore bodies as to size, location, mode of development, timbering, etc. The latter might again be divided into, first, data relating to work done in the levels, and, second, data relating to work done in the stopes. The former would naturally be gathered through the surveys, which would vary according to the amount of information found to be necessary for the office estimates, and to the desires of the engineer. It would be preserved through composite level maps indicating the relation of one sill to another, and by single level maps which would show more in detail the development of each sill floor.

The manner of collecting this information depends on several factors, and it is the object of this article to outline the simple and complete system adopted in the Butte district. As is well known, the ore bodies there are of such size that square set timbers are used in all drifts and in the stopes above them. The problem confronting the engineer was to devise such a scheme, dependent upon the surveys and the system of timbering, that with not too much refinement an accurate record could be maintained showing all the details relating to the stopes. Formerly it was the custom, in combination with the surveys and timbering, to arrange the stope book with reference lines passing through the center of the shaft and perpendicular to the strike of the vein, it has been modified to such an extent that the data may now be collected with much greater ease and accuracy.

To demonstrate the relation existing between the surveys and stopes, it will be necessary to describe the former only in so far as they bear upon the latter.

Beginning at the shaft, the survey on every level is run out to the face of each crosscut and drift as the work advances, being brought up to date once a month. Along the drifts, which are timbered with square sets, the points of the traverse are established on the caps, and wherever consistent the line of sight is made the center line of the drift. The angles are read in the usual manner, being doubled to avoid error, the magnetic bearing being taken as a check, the elevation recorded and the horizontal distance measured. Notes and sketches (and this is very important) are made, showing the timbering angles, side sets, stations, manways and chutes with their numbers—in fact, every detail—so that it may be possible to plat in the office stope book an accurate plan map of the level with the timbers as they actually stand in the mine. Upon these notes and the map made from them, the rest of the work depends to a considerable degree. Such a set of notes is given below:

	Azimuth.	Bearing.	Distance.	Station	Co-ordinates.		Elevation.
					N.	E.	
2371	344°-0'	N. 16° W.			3275.5	4576.4	5276.1
2372					+ .54	+ 56.0	+ .75
(2373)	285-27 89-27	N. 89°-27' E.	56'.0	(2373)	3276.04	4632.4	5276.85
2371	344-0	N. 16-0 W.			3275.5	4576.4	5276.1
2372							
2371	105-37 209-37	S. 89-27 W.	35.0	(2371)	- .34	- 35.0	.40
2372					3275.16	4541.4	5276.50
2375	172-17 261-44	S. 81-44 W.	29.16	(2375)	-4.19	-28.86	.22
2376	201-33 283-17	N. 76-43' W.	23.60	(2376)	+5.42	-22.97	-.27
					3276.39	4489.57	5276.45

Assume that the co-ordinates of station 2372 (Fig. 1), are, N. 3275.5; E. 4576.4, and that the elevation is 5276.1, while the true bearing from station 2371 to station 2372 is N. 16° W. Upon this basis the following calculations, determining the co-ordinates and elevations of the successive stations, explain themselves. A traverse table is used to obtain the northings and eastings.

Between levels development work generally consists of raises or winzes run from one sill floor to another, while the stoping of ore on each successive floor proceeds from these. Most frequently raises on narrow, almost vertical veins, are run from level to level, two sets wide along the lead and from "foot" to "hanging"—one set for the chute and the other for the manway.

Raise 691 is shown in Fig. 3 in side elevation, and a plan of the sixth floor is given to indicate the position of the chute and manway.

From the plan of the sixth floor it can be seen that the chute is to the right and the manway to the left, and that each occupies a foot wall set, while the side elevation indicates that the raise offsets to the "foot" one set for each floor.

The field stope hook is about 10½ inches long by 4½

inches wide, with stiff leather covers to prevent crushing and to protect it from the drippings of the mine waters. As a means of reference, the back is labeled or stamped with the name of the mine, the vein or veins for which the book is a record and the numbers of the first and last pages. The body of the book consists of sheets of cross-section paper of some convenient scale, each sheet being divided into squares

summing a length of vein of 400 feet and allowing two floors to a page and a couple of pages to each level for a longitudinal section, cross-sections of raises, winzes and such other notes as are likely to need tabulation, the book is divided accordingly. Thus the first two double pages are reserved for the longitudinal section, etc., of level one, while page 3 will have the lower half reserved for the twelfth floor.

Fig. 1.

Fig. 2.

Fig. 3.

of 1 inch by lines drawn heavier than the others, and every double page being numbered consecutively. A scale of 20 feet to the inch has been found to give good results in this work, as it is large enough to permit of plenty of detail and not so large as to be cumbersome. Each square represents a square set, while a dot at the line intersection is used to indicate a post. With such a scale the book on being opened will represent on a double page, allowing for margins, about 400 feet in length of the vein, and will be wide enough, where the veins are narrow, to permit of two floors being platted on the same sheet, one above the other.

To facilitate the work when in the mine, the book is arranged in the office according to a system. As-

Page 4 will contain floors 11 and 10, and so on down till we get to the first level, which will be on the lower half of page 9, with the first floor above it. The right hand edge of each page is marked for reference with the number of the floor opposite. On the ninth floor, where the level is, not only is the page marked, but a small leather tag with the number of the level is attached to the leaf, so that it protrudes beyond the edge. With the hook closed, then, one can easily locate any level desired, after which it requires but the turning of a few pages to get the floor wanted. This is a great help in the mine when taking stopes, as it saves much time. In a similar manner reservation would be made on the following pages for the data relating to the second level, and the place for each floor would be indicated as in level one.

Where the vein is more than 400 feet long, this being the number of feet that can be platted on one double page, the book is divided into as many parts as there are 400-foot sections. If the length along the lead is between 400 and 800 feet, the hook will be divided into two equal parts. The first half will contain a record of one section 400 feet long, from the top floor of the first level, through as many levels as the number of pages will permit; while the second half will contain a similar record of the other section of the vein. This arrangement readily shows the relation of levels, raises, winzes, etc., in any one section.

From actual platting in the mine, from the survey notes and from any other sources, the sketch of the sill floor of each level is made in the field book for the work of "taking up stopes" underground. In the case of 652 drift east and 653 drift west, Fig. 1, the field stope hook platting would be identical with that in the survey hook as shown. Too much care cannot be given in the preparation and platting of the stope hook and too much detail can hardly be added, for any error in the sill floor will be carried up through

\* Abstract School of Mines Quarterly.

the stopes, while lack of data may necessitate future trips to the mine where the conditions may be changed. Where the drift timbering is regular, that is, where each set conforms to the standard drift set for the mine, it is a simple matter to sketch in the posts of a set by a dot at each corner of a square. But many conditions arise where regular sets may not be used, and as the stope timbers above agree with the drift timbers or depend upon them for their correct platting, it is essential to indicate, since we cannot actually plat, just where and how each irregularity occurs.

Assume for demonstration that the drift is a straight one, except for a small bend, and that this bend can be overcome by a swing of 2 or 3 inches in one set, all the other sets being regular. The proposition would then be to indicate in preparing the field stope book, the position of this angle or bend with regard to the chutes, manways, stations, etc., on the sill floor, so that in showing the same bend in the stopes above, we will be assured of having it directly over that on the level. This is most important, since in a measure the relative position of chutes and bends is the means by which we quickly determine in the mine the correctness of the platting of the timbers in the stope book. Other irregularities arise, but these would be handled in a manner entirely similar to that which we shall use in explaining the method of "taking stopes" above drifts 652 and 653. With the sill floor platted and the stope book prepared, we may enter the mine to collect the data which next follows in the record. This consists in the correct representations of all chutes and manways that have been run, on all floors, in such a manner that we shall know at a glance their true position with regard to the level and stope.

We will consider that raise 691 is the only one to have been begun before the stoping began, the others in the true sense being simply chutes and manways at the side and being run simultaneously with the stope. The side elevation of the raise shows that it offsets one set to the foot wall for every floor gained in elevation. We will assume that the chute and manway is in every case in the foot wall set as on floor six. If the drift set be given any arbitrary number, say 10, and for every offset to the foot we add one, then the chute and manway of 691 raise would be in row 11 on the first floor, in row 12 on the second, and so on up. The side elevation would give us a correct representation of the offsetting to the foot wall, but from it we could not determine the offsetting to the east or west along the lead, should there be any. The plan of each floor furnishes this. Usually the chute goes directly to the next level without offsetting east or west along the lead, and in such a case the chute and manway would be platted on each sheet the same distance from the edge of the page. If it offsets one to the east it is platted one set to the right of the chute below, if to the west one set to the left.

Figs. 1 and 2 show the timbering of the sixth sill, 652 drift east and 653 drift west and the stoping above. Examining the sill floor sketch we learn from it that the work at the head of 651 crosscut north was completed June, 1902 (6-02), that 652 drift east was finished in July, 1902, and that during July and August 652 drift west was brought to its present condition. It also shows that in the set where station 2372 is, the girts are 7' 0 center to center, that the rest of the timbering of the east drift is regular (5' 0 center to center of posts), that drift 653 has two bends in it, which way these bends turn and the position and number of the chutes.

Floor one shows that chute 691 is in the "foot," that the stope is two sets wide, one set being directly over the timbers in the drift, and the other to the "foot," the position of the bends and other chutes, and the date at which the work was prosecuted. The marks on the different caps are notches which are put in the timbers to indicate the timbering nearest to the face, and to help the surveyor taking stopes to locate himself when he next begins the work. The other floors show in a similar manner the details of the stope above.

Once a month this work is taken up by the surveyor, who in company with the shift boss visits all the stopes where ore has been mined.

The objects of the field stope book are many. It furnishes a permanent record of the work in the mine, shows the manner in which the development was prosecuted, the date at which it was done, and supplies the data for office maps and estimates of amount of ore extracted, cost of same, and the possible ore reserve. From it the office stope book, which represents each ore body in its true relative position, is posted once a month; and through the information which it supplies a longitudinal section is made every six months and semi-annual estimates of ore reserve are furnished. In short, it shows the shape, location and manner of development of any stope at any time.

### Platinum in Cariboo, B. C.

The gravel beds lying in the ancient river valleys from Quesnelle lake westward toward Fraser river range from 400 to 600 feet in thickness. The gravel is estimated at 500,000,000 cubic yards, and is thought to carry 15 cents gold per yard. The water system

consists of 33 miles of canals reaching to three mountain lakes that have been converted into reservoirs. The camp is equipped in all departments. Mining is done with six No. 8 gaults, apertures 6 to 10 inches, and values are collected in 3400 feet of partly riffled sluice. Undercurrents, for the recovery of flour quicksilver and the heavy metals which resist amalgamation, are being erected at the dump.

The presence of rare metals of the platinum group in the concentrate, remaining in the sluices after a clean-up, has been suspected for some years. A sample of this residue taken last September showed the following:

	Ounces.	Gross Value Per Ton.
Gold.....	95	\$1,900 00
Silver.....	180	90 00
Platinum.....	64	832 00
Palladium.....	61.4	1,759 00
Osmiridium.....	42	1,356 00
Copper.....	10.5	16 56
Total value.....		\$5,993 56

### To Keep Water Pipes Clear From Refuse.

TO THE EDITOR:—No doubt the numerous readers of your paper who use water under pressure have had trouble in keeping leaves, cones, bark, etc., out of their water pipes.

The following way has worked quite successfully and may be of value to others using water under similar conditions.

To keep a uniform pressure the pipe needs to be full. To make sure of this, an overflow is provided for. This overflow water (a small amount only is required) is utilized to carry off the trash. This is accomplished by placing a sloping screen from the bottom of the supply box to the overflow opening. The screen needs to be of smooth strips placed parallel, with spaces smaller than the smallest nozzle used. The top surface of the screen must be smooth and even, with as little grade as circumstances will permit. In

Device for Clearing Head Gates of Pipe Lines.

the accompanying illustration the screen S has 1½ inch grade to the foot, but would do better with less. One recently put in for a Siskiyou county, Cal., mill is made of ¼x4-inch flume battens placed edgewise, ½ inch apart, and 10 feet long, with 8 inches grade for the 10 feet. This works very nicely. One was put in a large ditch in Montana a few years ago made of pieces of track iron 12 feet long, taken from an old car track. They were placed edgewise ½ inch apart on a frame of 2x4 scantling. The ditch is 3 miles long, but the screen needs attention only once in twenty-four hours at the worst season of the year and frequently goes a month without attention. The illustration herewith of one put in about fifteen years ago for a small plant shows the general arrangement of the others also.

The ditch A supplies water through gate E for the pipe T, passing through the screen S to the head box W, the surplus passing over at U. Placing the waste way box R L against and parallel with the supply box E S, also 2 inches lower, works nicely, but it is harder to prevent seepage through into the pipe, in case of a shutdown, than when built as shown.

Sand is better kept out of the ditch, but can be drawn off through a gate under U by having the box R L lower than E S, and by shoveling out above E R, or by all three methods, as circumstances require. Without an overflow, the leaves, etc., soon pile up on the screen S. Wire screen does not work so good as long strips.

The overflow opening must be smooth and level transversely, and as long as the screen is wide. So far as the writer knows, there is no patent on this arrangement.

E. L. BALLOU.

Igo, Cal., Feb. 22.

### THE PROSPECTOR.

The rock specimens from South Fork of Salmon river, Siskiyou county, Cal., are determined as follows: No. 1, talc, showing extremely thin, leaf-like gold in a number of places. No. 2 is also talc and similar to No. 1, but apparently from nearer the surface. It also shows a little gold. No. 3 is also talc, but is stained by iron oxide. No gold visible. No. 5 is granular to schistose rock containing a large amount of calcium carbonate, and is probablyankerite, a combination of calcium, magnesium and iron carbonate, a very common rock in the gold regions of California. There are several localities where talc contains gold in California, notably in Amador, Tuolumne and Calaveras counties, in addition to this occurrence in Siskiyou county. These rocks are all the result of alteration of old intrusive rocks. No. 4 is quartz containing pyrite and a little copper sulphide, also free gold.

The rock sample from San Bernardino, Cal., marked S. A. J., is a sedimentary rock, probably a volcanic tuff. The pebble-like portion on one side accompanied by pyrite is probably fragments of the rock mass, which has been crushed and the angular edges removed by decomposition. These pebbles are rather harder than the light gray portion, and contain crystals of hornblende and feldspar, and suggest the probability of the rock from which they were derived having been andesite.

The rock samples from Oracle, Ariz., are: No. 1 is anamesite, a medium-grained basaltic rock, very similar to diabase. The bright crystals are iron sulphide (pyrite). No. 2 is evidently the result of the silicification of the same kind of rock. It contains abundant free quartz and some pyrite. If this rock is the foot wall of the vein it should be crosscut until a normal rock (one showing no quartz, something like

No. 1) is reached, for there may be more ore than that contained in the small vein. No. 3 is apparently from a different place. It consists chiefly of quartz, black mica (biotite) and light green epidote. The latter is probably the result of the alteration of hornblende.

The diamond-drill cores from Hadley, Alaska, Nos. 54, 118 and 206, are altered greenstone, probably diabase. No. 62 is largely composed of epidote, resulting from the alteration of pyroxene or hornblende in an original rock, possibly a diorite or granite. No. 141 is composed of epidote and chloritic mineral, a small amount of pyrite and considerable finely disseminated calcium carbonate, one of the products of alteration. No. 173 consists chiefly of epidote and pink orthoclase, with calcium carbonate. This piece suggests strongly the granitic origin of the rock. None of these rocks are typical, all being greatly altered and difficult to determine as to origin.

The rock specimen from Lucile, Idaho, is largely composed of feldspar, with a little quartz, and what appears to have been bornblende. It is too much altered to make identification positive, but it seems to be either diorite or a phase of grano-diorite. It also shows iron oxide, evidently the result of the alteration of pyrite. It may be gold bearing. A piece from greater depth would probably afford more satisfactory results.

The dark colored rock from the Whitlatch mine, near Helena, Mont., is a fine-grained, somewhat silicified granite, though from a casual inspection of a piece not having a fresh fracture across the grain one would scarcely think it to be granite. No. 2 is

aplite (largely quartz). This rock corresponds closely to J. E. Spurr's alaskite.

Those sending mineral samples for identification are requested to wrap them carefully and to always either write name on the wrapper, or place a card or other means of identification inside the package, as well as a letter explaining the occurrence of the specimen. There is now on the Prospector's desk a sample (two pieces) of dark colored mineral in quartz. They came in a square nitro cap box, but the name and address of sender is unknown. If the sender will send name and locality where this was found the determination will be published in The Prospector.

In the determinations of rock samples from Bodie, Cal., in the issue of Feb. 25 a mistake was made in the numbers. Nos. 1, 2, 3 and 4 were correctly given. No. 5, and not 7, is a fragment of rhyolite, decomposed by surface weathering. No. 6, and not 5, is the galena-bearing rock, and No. 7 is opal, there being no No. 8 in the lot.

The small mineral sample from Chloride, Ariz., is not scheelite, but quartz. The quartz crystals can be plainly seen with an ordinary magnifying glass, and these have the characteristic striations on the sides of the crystals and the pyramidal terminations.

The minerals from Manse, Nev., are: No. 1, kaolinized feldspar. It is probably an altered dike rock, or a portion of one altered to kaolin along the contact. No. 2 is hematite, an ore of iron.

The rock specimens from Holmes, Wyo., are: The dark colored, glistening mineral, specular iron, a variety of hematite, with quartz. The white rock, chalcedonic quartz. It may be sinter from springs carrying silica in solution, as in the Yellowstone Park in Wyoming.

The rock sample from Greenhorn, Or., is talc schist, colored by iron oxides. It may be gold-bearing.

The rock from St. Louis, Mo., is a very much altered dike rock, probably felsite. The bright yellow and red colors are due to iron oxide.

The tailings from Hughes creek, Fresno county, Cal., are evidently from a silicified hornblende schist, such as is frequently found in Madera and Fresno counties. The green material is hornblende and also grains of quartz filled with dust-like particles of hornblende.

The two samples from Poker Flat, Cal., are talc schist altered from dolomite or ankerite. Both samples contain pyrite and may possibly contain gold. This character of rock is abundant in the Mother Lode region of California.

The black sand tailings from Columbus, Neb., should be submitted to a cyanide expert for test. The Prospector does not make determinations of this sort. The sand consists chiefly of quartz grains, magnetic iron sand and particles of metallic iron.

The light blue crystal from Ibapah, Utah, is beryl, a silicate of alumina and glucina. It has a hardness of 7.5 and possesses all the ordinary physical properties ascribed to that mineral by Dana.

The mineral specimen from Cecilville, Cal., is a mixture of pyrrhotite, a magnetic mono-sulphide of iron and calcite, which appears in a group of rhombohedral crystals. The pyrrhotite may contain nickel, as this is not an uncommon occurrence in pyrrhotite.

The ore from Daggett, Cal., is bornite (copper sulphide). The rock from the same place, said to be the wall rock of the copper vein, is quartz porphyry.

# Gold Mining in Rhodesia.

NUMBER V—CONCLUDED.

Written for the MINING AND SCIENTIFIC PRESS by F. C. ROBERTS.

GOLD RETURNS.—At the present time all declarations of gold output are made in "bullion" ounces.

The mining ordinance in Rhodesia demands that all declarations shall be accompanied by affidavits covering the actual monthly "cleanup" made by individual companies as well as by private enterprise.

The same form is requested by the local Chamber of Mines; the latter organization publishes the returns.

Unfortunately the unit used in these declarations (the bullion ounce) may vary from 300 to 950 fine. It is obvious, therefore, that to attempt to calculate, for the purpose of comparison or otherwise, using the figures published, without being in possession of the figures referring to the fineness of the gold, is a waste of time. The elasticity attending such a method of dealing with gold is very great and could be utilized for purposes of much graver importance than appears at first sight. It would be far better to exclude the "troy" ounce altogether and substitute dollars and cents than to continue to use a method which offers so much room for abuse.

Surely the industry has reached a point where at least the fine gold unit can be adopted, so that comparisons and calculations may be made by persons other than those who are intimately associated with the working of the mine.

The monthly production of gold (bullion) in Rhodesia has reached 23,000 ounces. There are two or more mills of fair capacity under construction and a number of 5-stamp propositions talked of, which should contribute to the output during the next year. With these increases, and some intelligent arrangements made to ensure a constant supply of unskilled labor, the probabilities are that the 40,000-ounce mark will be reached within the next few years.

Continuing a consideration of the costs of mining, we have the following:

PUMPING STATION.

A Prospecting Camp in Rhodesia, S. A.

Reopening an Ancient Mine in Rhodesia, S. A.

## Mining and Metallurgical Patents.

PATENTS ISSUED FEBRUARY 28, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

ORE FURNACE.—No. 783,903; A. Skoog, Shreveport, La.

In quicksilver furnace, combination with plurality of vertically disposed alternately arranged fire and ore chambers, transverse partition in fire chambers, oppositely located fire boxes, one for each fire chamber, fire chambers having openings in their walls through which products of fires are delivered in opposite directions, tiling arranged in ore chambers in staggered formation whereby sinuous passage is provided for ore, tiling arranged to provide passages at extreme ends of chambers through which products of combustion will travel upwardly, means for feeding material to ore chambers, and means for discharging ore from chambers.

PROCESS OF EXTRACTING COPPER FROM ORES.—No. 783,600; G. H. Waterbury, Denver, Colo.

Process of extracting copper from ores, consisting first in placing suitable pulverized ore in tank containing solution of sulphurous and sulphuric acid, introducing air and steam to solution under suitable pressure, drawing off solution from leaching tank into precipitating tank containing metal sufficiently divided to allow solution to circulate therethrough, and finally introducing steam, or air combined with steam, to precipitating tank, whereby copper is caused to settle in tank.

HEATING DEVICE FOR USE WITH LIQUID FUEL.—No. 783,898; A. R. Scherding, Paris, France.

Nozzle for mixing and ejecting liquid fuel, comprising means for forcing fuel in tubular stream, means

for mixing supporter of combustion under pressure with fuel, means for forcing mixture in tubular stream, means for supplying supporter of combustion to center of fuel stream and means for supplying tubular stream of supporter of combustion to outer wall of fuel stream.

PROCESS OF SMELTING ORES IN BLAST FURNACES.—No. 783,044; J. E. Johnson, Jr., Longdale, Va.

Process of smelting ores in blast furnace, feeding separate bodies of ore and fuel into furnace, smelting charge and increasing amount of heat available for smelting, and especially for those reactions which require high temperature, by supplying blast containing excess of oxygen, and utilizing heat in fuel by passing gases escaping from furnace through incoming body of ore and maintaining them out of contact with incoming fuel, waste gases thus being high in carbon monoxide and nitrogen.

ROCK DRILLING ENGINE.—No. 783,638; J. G. Leyner, Denver, Colo.

Fluid pressure drill, comprising cylinder, piston having longitudinal bore, hollow tool, water supply pipe extending into bore of piston, valve for pipe, and means whereby the pressure fluid opens valve when drill is in operation.

ROPE AND BUCKET CLIP FOR AUTOMATIC AERIAL WIRE ROPE TRAMWAYS.—No. 783,647; B. C. Riblet, Spokane, Wash.

In rope and bucket clip, clip bar, button on clip

adapted to be connected to tramway bucket, yoke strap connected to clip bar, and adjustable means for securing traction rope to clip and yoke strap.

FURNACE ARCH.—No. 783,778; G. L. Davison and D. R. Mathias, Chicago, Ill.

In open hearth furnace, combination with main chamber, of upper and lower flues leading into one end thereof and horizontally and transversely extending divisional arch separating upper and lower flues at or near point of entrance to main chamber.

SMELTING FURNACE.—No. 783,535; M. Murphy, Pueblo, Colo.

Smelting furnace having elliptical melting chamber, bottom of which is inverted elliptical arch having single row of bricks along each axis which do not break joint at point of intersection of rows, and having quarter sections filled in with bricks arranged in rows at right angles to each other, all rows in quarter sections and along axes extending into side walls of furnace.

ORE SEPARATOR.—No. 783,931; J. M. Couper, Atlanta, Ga.

Inverted conical vessel having outlet below top, means for introducing pulp into vessel tangentially thereof and above outlet, pipe leading from outlet, and delivery end of which is located at same level as that at which pulp is introduced into vessel, and means for catching gold associated with vessel.

## MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

### ALASKA.

The Pacific Coal & Oil Co. of London has given up the idea of striking paying oil in the region of Kayak island, on the southern border of Controller Bay, Gulf of Alaska. A dark brown—very viscous—petroleum has been found, but not in paying quantities. But in drilling for oil the coal prospects found warrant further development, which will be carried out. Manager A. H. Stracey of the Pacific Co. has left for London, but will return to push work. C. Cunningham will put a large force at work this season on a 40-foot vein that he has been prospecting for two years.

At Berners Bay the Gold King Co. is developing its properties under the direction of F. K. Muir of Portland, Or.

### ARIZONA.

#### Cochise County.

W. H. Pratt of San Francisco, Cal., has bonded and leased twenty-four claims near Paradise from Roe, Gill & Epply, and will start development work.—Manager Lewintownsky of the Savage mine, near Paradise, will sink the main shaft 500 feet before crosscutting.—At the Cochise Con. Co. work is progressing rapidly. They are rushing their three shafts and are making good headway in their adit to tap the zinc vein. They are arranging for machinery.—W. G. Rico of Houghton, Mich., has bought the Rieder group, near Paradise, and will start work on the property.—The Leadville mine, near Paradise, has been bought by A. Snedden and W. Cox of Tombstone, who will push development.

#### Gila County.

(Special Correspondence).—The Keystone copper group, 8 miles from Globe, has been sold by Findletter & Harvey to G. C. Campbell and others, of St. Louis, for \$300,000. J. C. Erman was active in aiding the sale and is manager for the new owners. The high-grade ore that the property has been shipping for eight years is about exhausted, but large bodies of medium and low grade siliceous copper carbonates are to be cyanided. A leaching plant is to be bought and put up immediately. Globe, March 6.

N. L. Amster of Boston, interested in the Arizona Commercial Copper Co. at Globe, and B. F. Close, superintendent of the Helvetia Copper Co., who will act as consulting engineer for the Arizona Commercial Copper Co., have made an inspection of the company's Copper Hill mine and laid plans for development and the purchase of new equipment, to include a hoist capable of sinking 1200 feet, air compressor, machine drills, etc. The company has purchased the 150 H. P. marine hoisters in the Rescue mill at Miami. These hoisters will be put in at the Copper Hill mine with the new hoist and the present equipment will be set up on the Black Hawk mine, where a new shaft is to be opened, miners having already begun to grade preparatory to sinking. It is probable that the surface track will be extended from the Gray mine, and Copper Hill ore trammed (using either horses or an electric motor) to the Old Dominion smelter. There are about 60,000 tons of 5% to 6% ore on the dumps at the Copper Hill mine.

#### Graham County.

After a shutdown on account of the recent floods, the reduction works of the Arizona C. Co. have resumed operations. As Chase creek has again broken out from the confines of its channel and endangered the plant, the company contemplate building a wall the full length of Clifton to keep the water in the channel. The wall will commence at the west end of Clifton, where Chase creek enters, and continue beyond the A. & N. M. station.

#### Maricopa County.

(Special Correspondence).—B. Ford has sold claims in the White Tank mountains to Eastern capitalists.—G. Hamlin, of the Relief mine, has sixteen men at work underground and more will be added soon.—J. E. Mad-dox will put men at work on his gold property, west of Phoenix.

Phoenix, March 7.

#### Mohave County.

In the San Francisco district the 10-stamp mill at the Blue Ridge mines will be started March 15. The mine is showing up well under recent development.

C. D. Pickering, superintendent of the Yucca Cyanide M. & M. Co. at Cedar, reports that he will sink 200 feet below the 400-foot level on the San Francisco mine. Owing to soft roads and inability to get oil to the mine, the mill has not been started up.—O. F. Kuencer of the German-American mines, near Vivian, reports that the mill is on the ground and that the work of assembling it will be commenced. Roads have been built to connect all the properties with the mill. From the Pioneer and 35th Parallel an even grade has been made on which track will be laid and the ore run to the mill in cars. The mill will be of 10 stamps capacity.

It is reported that C. G. Andrews and C. L. Doron of Los Angeles, Cal., will build a 500-ton smelter at McConico, 4 miles south of Kingman.—P. H. and A. H. Smith and M. A. Sawyer have located what appears to be a large deposit of wolframite on the east side of the Cerbat range, 8 miles north of Kingman. The ore occurs in dikes of feldspar.

#### Pinal County.

(Special Correspondence).—Owing to numerous washouts on the railroads, work at the various camps has been suspended for the present. Among the camps affected by the washouts are Troy and Superior.

Phoenix, March 7.

The Saddle Mountain M. Co. of Kelvin has placed an order for a 250-ton smelting plant, to be erected within a few months.

#### Yuma County.

H. L. McCarn, superintendent of the Planet Copper Co. at Planet via Yucca, reports that the company is opening up good ore bodies in the Planet mine. From the bottom of the shaft a drift has been run off on the contact and an ore body several hundred feet in length has been entered. This drift is now in 700 feet. It is proposed to sink another shaft to cut the contact below the head of the canyon and connect with the upper works. The ore opened up is rich in copper and other values. The company has twenty claims in the Harewan district on the Bill Williams fork of the Colorado river. The ore occurs as hedged veins and lenses.

### CALIFORNIA.

#### Amador County.

The leasers on the Defender at Defender have opened up a 9-foot ledge on the 200 drift and will start the mill.

#### Calaveras County.

C. Bennett and G. Knapp of Mokelumne Hill have struck good gravel on the Maloney property near China Gulch.—The owners of the Campo Seco copper mine are constructing a wagon bridge across the Mokelumne river, opposite the mine, to secure quartz rock for fluxing purposes, which is scarce within easy distance of the smelters on the Calaveras side, and plentiful on the Amador side.—The Stanislaus M. Co. has been formed to work the Duchess mines at Vallecito. W. E. Emery is secretary and manager at Vallecito. A vertical shaft has been sunk 75 feet, but the great amount of water encountered stopped this, and two tunnels have been run to open the vein, the lower one having been run 1824 feet. The property has a 10-stamp mill.

The Chris. Anderson mill is being run by the San Andreas Gold Channel M. Co. on rock from their gravel mine, near San Andreas. Electric lights have been placed in all the drifts and car runways of the mine.—The machinery of the San Andreas Blue Gravel M. Co. has been started. The work of sinking on the shaft will go ahead with an added force.—The Duryea mine at Central Hill, under the management of D. A. Nuner, is meeting with success in development work, and a large force will be put to work.—The new 10-stamp mill of the Benson mine has started at Altaville. A 70 H. P. hoist has been ordered.

E. C. Thwaite of Stockton reports that the 5-stamp mill of the Gertrude mine at Angels Camp is to be enlarged to twenty stamps.

#### El Dorado County.

Development work is being pushed on the Oliver quartz mine, near Greenwood, by Superintendent H. E. Laederich.—Superintendent C. F. McCracken is working the Summit Hill quartz mine in Spanish Dry Diggings, near Georgetown, with seven men.—The Short Handle quartz mine in Spanish Dry Diggings district is being unwatered by J. Federwitz, who has bonded the property of L. Sites and E. F. Lane.—The Union gravel mine, formerly the Delwisch, on Fort hill near Georgetown, is equipped with a pulverizing mill, which is operated by steam power. The mill is built to make twenty-four revolutions per minute and will work on an average 125 tons of gravel in twenty-four hours. The channel in this mine is several hundred feet in width and yields coarse gold. T. A. McCullough is the president and general manager, J. N. Isgrig superintendent and H. Ward foreman.—At the Clipper quartz mine, near Georgetown, H. G. Koppius is sinking several prospecting shafts.

#### Kern County.

Alexander Dallas of Bayonne, N. J., is in Bakersfield, projecting a new independent pipe line from Coalinga to Alviso, the head of navigation of San Francisco bay. He has rights of way for the entire distance of 134 miles between the two points, has the pipe purchased for the line and the money is ready for the construction. The company has contracted to purchase 10,000,000 barrels in the Coalinga field and it is said that a market has been found for the product. The pipe will be 8 inches and the capacity will be 10,000 barrels a day of the light Coalinga oil.

There are fourteen strings of tools running in the Kern River field, but no new territory is being exploited with the exception of the proposed deepening of one of the wells on the Grace lease. The deepening of this well will be for the purpose of settling the question as to whether or not there is still another lower sand in the Kern River field.

#### Mono County.

(Special Correspondence).—The Standard Con. M. Co. is dropping twenty stamps on ore from its several veins. Crushing is done in cyanide solution in the battery, the coarse, free gold being amalgamated on copper plates, and the vanner tailings are sent to a Moore slimes filter plant. Sizing is done by spitzkasten and the sands slimed in a tube mill. T. J. Hoover is superintendent of the Standard Con. M. Co. and E. H. Nutter is assistant superintendent.

Bodie, March 4.

#### Nevada County.

(Special Correspondence).—The Esperance Hydraulic Co. wishes to build a restraining dam at French Corral preparatory to working the auriferous gravels of the Esperance mine. T. McGuire of Grass Valley is making a topographic survey, estimating the drainage area, rainfall, etc., for a report to the Debris Commission.—A. Dahlberg of French Corral will resume work on the Slide mine on the South Yuba.

French Corral, March 7.

The Golden State M. & D. Co. has been formed to work the Noramhagua mine, owned by the Wm. Campbell estate and situated near Forest Springs.—F. J. Hellen of Pennsylvania is president, B. Goodwin of San Francisco vice-president, C. H. Barker of Grass Valley secretary, E. J. Rector of Nevada City treasurer, and A. Maltman of Nevada City manager.—A 2-drill air compressor is being installed at the Banner gravel mine at Canada Hill, near Nevada City. The Banner company is in good gravel and has been rigging up its washing plant during the past month, which is ready for operation.

#### Placer County.

At the Bellevue, near Ophir, P. S. Lozano and A. N.

Buchanan are hauling machinery from Blue ravine, near Folsom. They will put in an air compressor plant, machine drills, new hoist and straighten out the shaft. This mine has been paying under the management of P. S. Lazano.—C. A. Reed is working men at the St. Lawrence, near Ophir. He has crushed a lot of ore at Malmberg's mill with good results.—The 5-stamp mill recently built at the Bouk is running to its full capacity.—The Tadpole at Canada hill will build a mill with a capacity of sixty tons per day.

At the Star United mine, near Iowa Hill, the company have opened up the old tunnel and are running for the back channel. This is part of the Old Wolverine channel, which was a great producer in the early days. I. E. Rose is the superintendent.—The McGeachen mine has been bonded by a company, represented by I. E. Rose as manager, who have extended the tunnel and have struck gravel. They will commence breasting in a few days, as soon as they can get ground opened up.—It is reported that the pay channel has been encountered at the Prospect Hill (old Big Dipper) mine, south of Iowa hill.—Men are opening up the Lehanon tunnel, near the old Big Dipper mine, and the company expect to strike gravel in a short time.

#### Shasta County.

A 4-stamp quartz mill is to be built on Mule mountain, three-fourths of a mile from Centerville, by J. T. Jensen of San Francisco. E. Markwick has charge.

#### Sierra County.

A fine chimney of gold bearing quartz has been opened in the Empire mine in Gold valley, 14 miles north of Sierra City. A. N. Butts has charge at the mine.

#### Siskiyou County.

J. Derry & Co. have sold the Derry quartz mines on Klamath river, north side, opposite the Williams place at Anderson Grade Ferry, to Eastern capitalists for \$25,000. The company intends putting up a 10-stamp mill.

The Tyrer M. Co. has bought the mines owned by J. Hamilton at Oro Fino. Tyrer, the general manager, will sink shafts, run tunnels and put in a new 10-stamp mill, to be operated by electricity.

#### Sutter County.

The fine gold in the black sand on C. J. Kirk's land at Harkey's Corners is to be worked by a new process by Jos. Moore & Son.

#### Trinity County.

The Gold Dollar M. Co. has been formed by J. Elliott, W. C. Bissell, F. C. Meckel, S. M. Gibson and J. A. Wallace to work the Gold Dollar mine on Canyon creek, near Lowden ranch.—Work has begun on the lower tunnel at the Lappin mine at Deadwood. This tunnel will be run 900 feet. An upraise will then connect it with the upper levels and the body of ore opened up will be mined and milled. Owing to the expense and difficulty of handling the water in the upper levels, no work will be done until the tunnel is completed.

#### Tuolumne County.

Philips & Grundy will put a 5-stamp mill on their claim, between the Carlon ranch and Deer creek, near Groveland.—A. W. Bryant of Carters, superintendent of the Prudhomme mine, will treat the tailings by the cyanide process.—The Bluebell M. & M. Co. has its hoist and hoiler in place on the Hardtimes, near Arastaville, and gallows-frame completed and has begun sinking the shaft 100 feet below the present level, which is 60 feet. As soon as the Hardtimes is under headway the company will begin sinking the Bluebell shaft to a greater depth.

### COLORADO.

(Special Correspondence).—The litigation of 12 years between N. A. Munn and the Ithex Co. of Leadville has been decided in favor of Munn for \$266,000, amount due for his share in the property and for ore removed.—The suit of the Jerry Johnson G. M. Co. and the United Gold Mines Co. has been settled at Cripple Creek.—The District Court at Leadville has made permanent the injunction brought by the Leadville union miners against the operators to prevent the operators from using the card system. This system is being used in other camps throughout the State with effect against the Federation, but it seems that the operators will be obliged to try some other scheme in Leadville or be in contempt of court if they continue to use the card system. The card system was adopted in Leadville in the fall, and before it became permanent the court granted temporary injunction at the request of the Western Federation of Miners. It is claimed that the card system is having telling effect in the Cripple Creek district, and that no man is allowed to work in the district without a card from the operators' association.

Denver, March 7.

#### Boulder County.

The Wolf Tongue M. Co., operating at Nederland, shipped a carload of tungsten concentrates to Pittsburg, Pa. The concentrates are valued at \$450 per ton, and there were twenty tons in the consignment.

#### Clear Creek County.

The Grouse group of seven claims on the south slope of Bellevue mountain, at the head of Hoosac gulch, has been bonded and leased by J. W. Boyd of Idaho Springs for Buffalo and New York capitalists, and the work of cleaning out the workings has been started. A tunnel, in 700 feet, will be continued.—The breast of the Black Swan tunnel, on Chicago creek, has entered a good streak of milling ore 550 feet in from the portal. The property is owned by the Chicago Mountain M. & T. Co. H. R. Baker of Idaho Springs is the local manager.—Manager R. B. Morton has started the Jo Reynolds concentrating mill near Idaho Springs and is putting in a sampling plant.—W. W. Cannady and J. Cummings have resumed work on the Burns-Moore tunnel, which is in 1625 feet.—The Black M. Co. has started work on the Alpha mine in Gilson gulch. W. P. Black of Idaho Springs is manager.—C. Peer has charge of development work at the Wheatland mine on Trail creek.—Work has been resumed at the Josephine group on Chicago creek.

The McClelland tunnel is now in 3500 feet and is making from 7 to 8 feet per day in the heading. Since the

mishap of the big cave some months ago, by which progress was delayed and an immense amount of trouble engendered, there has been nothing to retard the work. That piece of difficult ground has been effectually caught up and timbered so that no more trouble may be feared from that source. The tunnel is now upon the last lap of its course to its primary objective point—the Freeland vein. From 1500 to 1700 feet more and that vein will be reached.

The Helen mine tunnel in Virginia canyon is still being driven ahead on the vein.

#### Custer County.

The Lone Star M. Co. of Pueblo has opened rich ore on Texas creek, near Silver Cliff.—The water has been reduced in the Toledo shaft and the track has been laid at the 250-foot level. Three shifts are at work.—The ore mined at the Silver Bar property, near Silver Cliff, is being run through the new experimental mill.

#### Eagle County.

The lease on the Spirit mine at Red Cliff has been taken by the Pittsburg Zinc M. Co. W. N. Buell has charge of the work.

#### Fremont County.

The Page mill, at Florence, has been destroyed by fire.

#### Gilpin County.

Gilpin county shipments for February amounted to 290 cars, or 6100 tons.—The Banzai M. Co. has sunk its shaft 210 feet on the After Supper, under the superintendence of A. Watters of Nevada. The company intends to sink 250 feet and then drift on both sides of the shaft. L. R. Tatum of Denver is president and manager.—Machinery has been put on the Hope & Parker shaft, in Phoenix district, to unwater the property for examination.—The Williams mine, in Lake gulch, is being worked under the direction of Eugene Drake.—Shipments of milling ores are being made from the 740-foot level of the Hawley-Gardner mine, on Quartz hill, being worked under the superintendence of J. Parks.—Operations are being carried on at the Alps in the 800 and 1300-foot workings, under the management of J. Williams. Upraises are being made to connect the 800 with the 600 and the 1300 with the 1200, and as soon as ground is opened up additional men will be put to work.—Harry, Tippet & Co. of Nevada are working the Forks mine, on Quartz hill, under a lease and bond. Work is being carried on between the 200 and 300-foot levels in sinking a winze and in upraising to open up the ground and to provide ventilation. Shipments of smelting ores are averaging about \$50 per ton, the last ore to the sampling works giving values of 22% lead, besides gold and silver values. The company is working with a whim, but may put in a small hoisting plant.—Mills & Crispin, leasing on the west 555-foot level of the East Notaway mine, in Russell district, have opened up smelting ores.—The Alice E. M. Co. has been formed by E. H. Campbell, D. D. Johnson and Arthur Ponsford to operate in the Phoenix district.—The Kemp-Calhoun mine, at the head of Leavenworth gulch, is being operated by Grenfell & Co. of Nevada. Their last shipment of first-class ores gave values of \$200 per ton, and their second-class ores gave values of \$100 per ton. The milling ores of this property, as a rule, are low grade. Work is being carried on in the 200, 250, 300 and 350-foot levels and the property has been opened up by sinking winzes and putting upraises between the levels.—Drennan & Co. are leasing in the 400-foot level of the San Juan mine, on Quartz hill.—Hauser & Co. are working in the 400-foot level of the Clark-Gardner mine, on Quartz hill.

#### Gunnison County.

At Ohio City six copper claims have been transferred from the locators—C. H. Mondell, F. Lockwood, W. Moines, A. Angman and F. M. Hudler—to R. W. Spensley & Co. for \$15,000. There is a 40-foot shaft and a 400-foot tunnel on the property. The new owners will begin taking out ore and develop the property. R. N. Spensley of Leadville has sold placer claims in Union Park, in the Tin Cup district, to A. Hartman and C. Stone for \$3000.

#### Hinsdale County.

The Golden Fleece mine and mill, near Lake City, are being put in shape for working by R. J. Kilvert.—It is reported that the St. Jacobs mine, at Carson, is to be opened up this spring under the superintendence of G. H. Zacharias.—The Czar, near Lake City, has been leased by L. A. Vinton and W. Swank.

#### Lake County.

(Special Correspondence).—An unusually rich gold strike is reported from the Ixeh mine on Breece hill, Leadville, which is being worked mainly by lessees.—The lessees on the Izard, on Little Ellen hill, northeast of the Ixeh, have carbonate carrying gold, silver and lead. The lease expires in a short time and the original owner of the claim, J. E. Izard, is in Leadville, and may work the property himself.—Fifty acres in Iowa gulch, in the southern end of the Leadville gold belt and including the Aurora No. 1, Aurora No. 2 and Cora May, have been leased from A. S. Sharp. There is a 525-foot tunnel starting on the Ready Cash claim and penetrating the Cora May and Aurora No. 1. The Denver people who have leased the property will begin development within the next twenty days.—A. V. Bohn is completing arrangements for the development of the Valley property in Evans gulch.

Leadville, March 7.  
On Bull hill, Echo canyon, in the Twin Lakes district, S. L. Dowell has started work on the Golden Fleece and Wabash properties, and the Last Chance Co. has started work on their shaft under the superintendence of S. Dodge.

#### San Miguel County.

The Tomboy M. Co. at Telluride is working 250 men in its mines and mill and is sending 300 tons daily to the new 60-stamp mill. The sinking of the Cincinnati three-compartment shaft, which is 300 feet deep, is to be continued. The shaft is designed as the bore from which the Argentine and Cincinnati vein will be developed. The vein will be prospected and developed in both directions from the shaft, and eventually it will be the main outlet through which the mines will be worked. The new mill is treating ore from the Tomboy mine

proper, a large portion of which is under lease to J. K. McCoy. During December the mill treated 9400 tons of ore, yielding a bullion value of \$38,000; 324 tons of concentrates were shipped, returning a value of \$23,500, the net profit over operating expenses and \$2400 expended for improvements being given at \$15,000.—Excepting the reduction in tonnage resulting from Wagner Bros.' cessation of work on the Smuggler-Union and Sheridan dumps, on account of freezing weather, operations on the Smuggler-Union mines are normal.—King & Lindsey, the Telluride Leasing Co. and smaller lessees are sending to Pandora about 400 tons of mineral daily. The new 60-stamp mill is taxed to its utmost capacity and most of the 80 stamps in the old mill are dropping constantly. The milling ore is concentrated on the basis of from five to eight tons into one, saving all the free gold values possible on the mill plates by amalgamation.—On the property of the Black Bear M. Co. in Savage basin drifts are being run on the vein in both directions from the bottom of the 150-foot shaft. It is the intention to build a mill the coming summer.

The Belle Champion mines in the Sawpit district, 17 miles below Telluride, have been sold by Anderson, Nulph & McDonald to an Eastern company represented by Mr. Grablin of Telluride for \$50,000.—A. M. Ballard will build a 30-ton custom mill in the Sawpit district.

#### San Juan County.

A. J. Aurand reports that two electric drills in the Bullion King crosscut at Silverton averaged 30 feet of holes each for every day in February.—The 3900-foot aerial tramway of the Old Hundred mine near Silverton has been completed and is running satisfactorily. The line runs at an angle of 45°.

#### Teller County.

The gold production from the Cripple Creek district for February, while necessarily lower on account of the short month, is up to the average. There have been no special features. The curtailed production from Stratton's Independence, due to the destruction of the ore bins by fire, is seen in the general figures. The leasing of the Stratton estate will not make itself felt during March, as it will take all of that month to get the lessees, with their new crews, in touch with the ground. The figures compiled in the camp are as follows:

	Tons.	Value.	Total.
U. S. R. & R. Co.	22,500	\$30	\$ 675,000
Portland	7,500	30	225,000
Dorcas	3,350	30	100,500
Economic	2,100	35	73,500
Wild Horse	2,000	6	12,000
King & Craig (Anaconda)	1,400	8	11,200
Other cyanide plants	800	6	4,800
Smelters	9,000	65	585,000
Totals	48,600		\$1,687,000

Kenzy and associates, who recently found a good vein carrying fair values in the shallow shaft on the Bob Lee on Tenderfoot hill, adjoining the Hoosier, near Cripple Creek, have completed a shaft house and will install a new and complete plant of machinery. The values are increasing as the work of development progresses. The vein was found in place at a depth of 12 feet.—R. Williamson, A. M. Keefer and L. Erickson who have secured a three years lease on the Oro claim belonging to the Colorado Springs M. Co., at 20% flat royalty, located on Ironclad hill, Cripple Creek, are now unwatering the shaft, which contains surface water. The shaft is down to 87 feet.

A rich strike has been made on the Mabel M. of the Gold Dollar property on the east slope of Beacon hill, Cripple Creek, by F. G. Worthington.—Machinery is being put on the Jerry Johnson property on Iron Clad hill by Blakeley and associates.

## IDAHO.

#### Blaine County.

The Wood River Zinc Co. has bought from W. D. Waters of Richmond, Va., the Nay Aug group at the head of Panther gulch, Deer Creek, and 2 miles from the mill that the Wood River Zinc Co. is building at its War Dance mines, near Hailey.

#### Boise County.

The South Lincoln mine, at Pearl, is being worked by Manager L. A. Wagner with sixteen men. The ores of this district consist of granular altered granitic gangue and quartz impregnated with pyrite, galena and sphalerite, the gold values ranging from \$5 to \$15 per ton, 25% to 30% being free milling.

The locators of the Oxbow placers, near Idaho City, plan to turn Payette river through a tunnel below Deadwood Fork and work the bed of the river, and utilize the water for power. If their plans are carried out, the water will have a fall of 48 feet at the mouth of the tunnel. A pipe line will carry it to Pine Flat 3 mile below, giving an additional fall of 62 feet. The tunnel will drain 2 miles of the river bed, and the pipe line will give 3 mile more of the river bed to be mined. The pipe will be 5 feet in diameter, of strips of wood 2x2, fastened with iron bands. The electrical machinery will be taken in next August. The tunnel, at first made 14 feet wide, 9 feet high on the sides and 12 feet in the center (it being arched), and afterward widened to 20 feet, as originally planned, is now being widened to 28 feet. The company expects to turn the water of Payette river through this tunnel May 1. Miners will then be put to work extracting gold from the bed of the river. Somewhere between 150 and 300 miners will be employed. The cost of the tunnel when completed will be about \$125,000. The estimated cost before the work was started was \$30,000, dimensions then to be 9 feet high and 20 feet wide. The extra cost was due in a great measure to hot springs that were tapped. Thirty tons of giant powder have been used to date in driving the tunnel. From 150 to 170 pounds have been used for each round of holes. The Idaho City World says the power that will be furnished during low water will be about 20,000 horse, and the electrical machinery will be of that capacity. The cost of the plant, together with freight, expense of installing, construction of pipe line, road, and other expenses to be incurred before the plant is ready to transfer power to Boise and vicinity and intervening points, will be about \$1,500,000.

G. Z. Edwards, superintendent of the Lincoln mine at Pearl, reports that the new three-compartment shaft is

200 feet deep and being retimbered with 10x10 timbers. The intention is to sink it 500 feet. It has been determined that the ore will cyanide well and a cyanide plant will be put in.

#### Idaho County.

The Diamond Chief M. Co. has bonded the Black Bear group of eleven claims, in the Big Creek district, near Warrens, to L. D. Lively of Omaha, Neb., representing Omaha, Neb., and Cleveland, O., capitalists. The Black Bear is a copper-gold property and has 500 feet of tunnel. A ledge 16 feet wide has given good assays. It is one of the older properties of the district, but has suffered because of lack of transportation and has never been worked on an extensive scale. The plans of the company include the erection of a smelter.

#### Kootenai County.

The Idaho Legislature has abolished Kootenai county and created the county of Clark from the southern half and the county of Lewis from the northern part.

#### Shoshone County.

It is reported that the Hercules M. Co. at Burke will build a 250-ton concentrating plant on Gorge gulch to work the reserves of milling ore.—J. E. Markwell of Wallace, manager of the Sister M. Co., says that engineers who have recently looked over the property report that in order to explore the ground thoroughly a shaft should be sunk to a depth of 400 or 500 feet; that the present tunnel cannot give sufficient depth. Estimates recently made place the expense of the necessary sinking and development at \$60,000. It will be necessary to install a compressor.

#### Washington County.

The Hancock Copper Mines Co. of Idaho has been formed by C. F. Drake, E. P. Rhea, G. A. Rahm of Weiser; J. Sennett and J. J. Curtis of Washington, D. C., to work ten claims on Camp creek, 2 miles above Landora. The ores are a gold-copper proposition and of excellent smelting qualities.

## MISSOURI.

#### Jasper County.

(Special Correspondence).—The mine of Scott & Co., on the Smith & Stickney lease, 3 miles north of Joplin, recently turned in 82,830 pounds of zinc concentrates. The owners of the mine are N. F. Stafford, Bert Davis, Gus Witsanski and W. H. Scott of Webb City, Mo. The company is planning to build a mill in the spring.—A new mill will be built at the Izanhart mine at Badger this spring.—J. G. Starr and G. C. Meese of Joplin, Valentine Boucher and R. F. Robertson of Galena, Kan., have secured a lease on eighty acres of the Hunt land, 7 miles northwest of Joplin. The company has put in pumps to drain the ground.—A new 100-ton mill is being built by Chapman & Co. on their lease at Webb City, Mo.—W. M. Scott and John Derby of Carterville, Mo., and C. W. Lake of Kansas City, Mo., have formed a company to work at Alba.—A mining company with E. B. Allen, Wm. Lotbain, L. F. Miller, H. Drew, J. McDonald, A. McDonald, N. B. Ristine and A. L. Mills of Joplin has been formed and has secured a lease on forty acres on the Amazon tract, north of Joplin. Fifteen drill holes are to be put down this spring.—Frank Nicholson of Joplin has let a contract for \$5000 worth of equipment to be installed at the Missouri Mule mine on the Providence lease at Webb City.—C. T. Orr of Joplin has sold to O. J. Raymond, W. A. Corl of Webb City and J. A. Bowman of Kansas City a forty-acre lease on the Missouri Zinc Fields land for \$8000. There are two good prospects on the land and two mills will shortly be built on them.  
Joplin, March 4.

## MONTANA.

#### Fergus County.

The Maginnis mine, near Maiden, owned by W. G. Conrad of Great Falls, is under the management of E. H. Crabtree. A 20-ton shipment averaging \$125 a ton has been sent to the East Helena smelter for treatment, this being the third shipment of the same kind since Mr. Crabtree took charge, and he says they will be made regularly hereafter until the company is prepared to treat the ore itself. More than 20,000 tons of big-grade free milling ore have been blocked out, and it is the intention to send the shaft, which is now down 140 feet, to a greater depth, and a hoisting plant will be installed as soon as possible. The old mill is being put in working order and will be started up.

#### Custer County.

The White Knob Copper Co.'s property has been recently worked by Receiver Clark with forty men. The main shaft is 700 feet deep, connecting with the 1500-foot Albert tunnel. The property is said to show a 23-foot vein carrying 3% to 9% copper and \$1.75 to \$3 gold and silver. The mine is connected with the smelter by a 10-mile electric railway, having a maximum gradient of 6% in a rise of 2000 feet. The smelter has three 200-ton furnaces and was blown in in September, 1902. The company was forced into the hands of receivers last October. It is stated that the trouble with the White Knob enterprise is that its expensive smelting plant and surface equipment were undertaken before the method of treating the ore was sufficiently worked out, as the bodies of carbonate and oxide ores have continued down 700 feet in that altered condition to the Albert tunnel level, and experience has shown that the ore lacked sufficient sulphur for a successful matting method of treatment with which it has been attempted to work it, and too much sulphur for making base bullion successfully. The sulphur and copper contents show increase in two short winzes that have been sunk from the Albert tunnel.

#### Lewis and Clarke County.

The Red Bird Co. of Helena, developing the Copper Hill claim, near Austin, has sunk 265 feet and has a 35-foot vein of copper and iron, which also carries values in gold and silver. A winze will be sunk 100 feet on the vein. The Red Bird Co. declared its usual monthly dividend for February.

A copper strike is reported at the Brooklyn Bridge mine, 5 miles south of Helena. The ore assays \$200 a ton in copper, in addition to gold values. A body of ore has been blocked out and shipment will be made. An

additional force of men is being put on. The ore is rich in copper glance.

#### Madison County.

The Mammoth M. & M. Co. is working the Leviathan and Mammoth mines under direction of A. C. Sanders of Mammoth. In July the company expects to increase its milling capacity, which is now ten stamps.—Chas. Estes has leased a small mill near Twin Bridges to work ore from his property in Nugget gulch.

#### Park County.

Superintendent F. Wartenweller of the Kimberly-Montana properties, at Jardine, reports that the company's stamp mill and cyanide plant are in operation. The company needs good miners who can run machine drills and a number of such can be given employment.

#### Powell County.

The dredger at Gold creek is in successful operation. The dredger has a capacity of 3000 cubic yards in twenty-four hours. Fourteen men are now employed. The company is figuring on putting in electric power next year, there being an unlimited supply of water in the neighborhood.

#### Silver Bow County.

(Special Correspondence).—On the Pennsylvania mine, at Butte, the three-compartment shaft is being sunk 200 feet deeper, taking it to the 1700-foot level.—The Montana Legislature passed no laws directly relating to mining interests or to the mining litigation of F. A. Heinze and the Amalgamated Copper Co.—The Leadville M. & S. Co. is preparing to open twelve claims 17 miles northeast of Butte.—The Mammoth M. & M. Co. has taken over the Leviathan and Mammoth mines, in the Mammoth district, and will increase the capacity of the 10-stamp mill.

Butte, March 6.

The Raven M. Co. has started sinking a shaft at Centerville under the superintendence of J. Berkin.

An air pipe line is being built from the Mountain Con., at Butte, to the Poulin shaft preparatory to exploring the copper silver belt by the Anaconda C. M. Co.—The Butte & Boston Co. has started work on the Berkley in the Meaderville district with twenty men. This is one of the rich mines of the Butte & Boston system, but little ore has been taken from it during the last few years on account of litigation, the company having been prevented from working it by an order of injunction. The shaft on it is 800 feet deep. The work will be confined to the repairing of the dilapidated parts. No ore will be mined at present.—The Rarus mine, of the United Copper Co., which was practically closed down January 30 on account of the flooding of the lower level, due to the breaking of a pump, has been started with 150 men. The breaking of the pump was followed by the breaking of the flat cable to which was attached a large tank for raising water, and the latter accident delayed the work of reducing the flood.—At the Reins property in Meaderville the water has all been taken from the workings and a new 800-gallon pump has been put in at the 800-foot level.—The Pittsburg & Montana C. Co. has placed electric pumps at the 700 and 1200-foot levels of shaft No. 2.

## NEVADA.

#### Emerald County.

High-grade ore has been found on the W. R. Hearst claim of the Hearst-Jagers G. M. Co. at Tule canyon, 33 miles southeast of Goldfield. The Hearst claim is one of a group recently purchased by G. Wingfield, W. J. Douglass and associates from T. Jagers, one of the pioneers of Tule canyon. A mill is to be built at the mine. The main shaft will be sunk 300 feet, from which level drifts will be extended and the ore shoot blocked out then.

#### Lincoln County.

The ores from the Abe Lincoln mine, at Pioche, are to be treated by concentration and cyanidation, as recommended by A. P. Donohue, who is at the mine. A cyanide plant will be ordered by Manager Scott.

Under the management of Mark Hopkins the purchasers of the Potosi group at Good Springs are installing the tramway to the railroad over which ores already mined and on the surface will be taken to the smelters.

Cunningham & Jewett of Marysville, Utah, are developing the Betsy group and M. Bryan of Los Angeles, Cal., is developing the Red Cloud at Good Springs.—The Keystone mine and mill at Good Springs have passed into the hands of a British syndicate for \$337,500. R. W. Rathbone is manager and expects to have the mill in commission before the end of the month.

A new camp known as Nelson has been established near the Techaticup, 10 miles west of Eldorado canyon. The camp is showing up bodies of high-grade ore, and is near the summit of Vegas mountains. In the Techaticup mine great ore bodies have been found and a hoisting plant is being installed and the mine worked in a systematic manner for the first time in its history.

#### Nye County.

To illustrate present freight conditions at Goldfield, it may be mentioned that a bakery there has been using an adobe oven. Recent rainstorms did considerable damage. The proprietors went to Reno, where they bought \$26 worth of brick, which was crated at a cost of \$30. They could not get the brick in by freight, so had it shipped to Goldfield as express at a cost of \$600. The Wells-Fargo Express Co. has notified Goldfield merchants that hereafter neither machinery nor brick will be shipped into Goldfield under any consideration. There were 2400 bricks in this shipment and the cost laid down in Goldfield was 30 cents per brick.

A Salt Lake man at Goldfield says: Following the custom in vogue during the early development of Tonopah, Goldfield and other camps, the leasing system has been adopted here and is apparently successful. There are 100 tents here, filled, pitched along what seems to be a main street. There are several saloons in the place, two general stores, one of which has quite a large stock of goods, several eating places and prospectors galore. Feed is high. Oats cost \$7 per 100 pounds, hay \$4 per hundred pounds and water \$5 per barrel. It looks as though most of the freight will come in here from California. Parties living in the valley below Hiko are haul-

ing hay and corn here for sale and that seems to be the cheapest point of supply. The country from Hiko to this place looks good for prospecting. Ground around here is staked off for 6 miles, in the valley as well as the hills.

#### Washoe County.

At the annual meeting of the Springfield-Nevada M. Co. at Springfield, Mass., P. A. Shorman, the treasurer, reported the company to be in a first-class financial condition, all bills being paid to date, with \$8000 in the treasury. Ira Miller, the president, gave a report of the development work during the year, a description of the new pipe line, which conveys water to the company's two mills and increases its water supply. Most of the pipe has been laid, and it is expected that the mills will resume operations at once. Officers were elected as follows: I. Miller, Westfield, N. Y., president; R. F. Monroe, vice-president; P. A. Shorman, West Springfield, Mass., secretary and treasurer. The company owns 1000 acres of mineral land at Olinghouse canyon. It has four mills in operation.

At Olinghouse the Springfield-Nevada M. Co. have forty men working on the Dondero and Williams claims and are working both their mills; J. W. Sheehan is working the Crown Point; R. Nonis is stoping ore in the Forlorn Hope; Harvey & Nichols are taking ore from the Oro; H. Grant of Truckee Meadows has leased the Renegade No. 2; E. Olinghouse has men at work at the Green Hill, and J. A. Ingalls is developing the Micaga group. In the White Horse district, Golden, Frazier & Wetmore of Wadsworth are working the Emma L., on the Addie C., W. Williams is putting a hoisting plant capable of sinking to 500 feet.

## NEW MEXICO.

#### Grant County.

Two hundred men are employed by the Burro Mountain Copper Co. at Camp Leopold in the Burro mountains. Improvements are under way which will increase the capacity of the plant from 150 to 200 tons daily. New machinery has been added to the 100-ton concentrator. A large reservoir is being built  $\frac{1}{2}$  mile down the canyon, below the concentrator, and a pump, with 200,000 gallons a day capacity, has been installed. It has been impossible to haul the concentrates to the Silver City smelter, owing to bad roads, but the mill has been running steadily. The plant has been averaging a shipment of twenty-five cars a month and with increased water supply the shipments will be increased.

#### Lincoln County.

The Wisconsin M. & S. Co. has been formed by C. L. Scheler, Madison, Wis.; E. H. Talbert, Jicarilla, N. M., with W. A. Melvers, Nogal, N. M., as manager to build a 50-ton custom, milling and concentrating plant, in the Jicarilla district. The Jicarilla district is 10 miles northeast of White Oaks and 7 miles southeast of Ancho on the El Paso & Northeastern Railway. The country, rock is an altered granite. This region has been worked chiefly by placer miners in the past. A belt of copper has been found to pass through both the east and west sides of the district. L. A. Fox is working a copper deposit.

#### Rio Arriba County.

The Pay Roll claim of the Keystone-Bromide M. Co., at the 250-foot level, shows a vein of sulphide copper ore 20 feet in width averaging \$30 per ton. The ore also carries gold. In the Gold Pan, the Danbury group, the Red Fissure and other claims the gold values exceed the copper, but they are valuable as copper properties. The Sixteen to One and the Hutchison claims carry greater values in silver than in copper. Copper is found on every claim, ranging in value from 2% to 20% of the ore.

#### Sierra County.

The placers at Shandon in the Caballo foothills, skirting the Rio Grande, have been dormant, the locators holding back, waiting for some one else to do something for them. A new town has been laid out on the Rio Grande above the mouth of Apache canyon. It is called Shandon. The gold that comes from Shandon is purer than any of the other placer gold of the southwest. The output from the Shandon gold field averaged \$1000 per month. The gold was mostly obtained by native miners who owned the richest surface ground and were the closest to bedrock. The gold was mostly obtained by the blowing process, the mouth serving as the blowpipe.

Parker Bros. of El Paso have several hundred acres of placers in Trujillo gulch and are putting up hydraulic machinery to ground sluice this gulch. A 6-inch pipe is being laid to the reservoir, 2 miles from the river. It is calculated that with the triplicate pump now being installed enough water can be thrown into the reservoir above the placer grounds every twenty-four hours to furnish abundance of water for an eight-hour run.

Goss Bros. of Salt Lake City, Utah, have a bond and lease on 640 acres of ground belonging to the Silvas. They will put in machinery to operate the placers on an extensive scale.

## OREGON.

#### Baker County.

W. H. Burchdorf has driven a 176-foot crosscut tunnel through soapstone at the Big Bonanza, 7 miles northwest of Sumpter, in the Bald Mountain district.

The Empire and Phil Sheridan mines, on Granite creek, near Granite, have been acquired by Wheeler & Co. of New York from C. S. Miller of Granite, who built the Monumental mill, the first in the district.

F. D. Smith of Sumpter has secured the Psyche and Diadem mines in the Greenhorn district and will develop them.—J. G. Kirchen of Sumpter has finished plans for a 100-ton mill to be put up at the Friday mine by the N. J. Sorensen Co.—G. Pearsons, owner of the Treasure Box and Yankee Girl claims, 2 miles east of Sumpter, reports that he has sunk a shaft 20 feet on the Treasure Box ledge. This has been crosscut and found to be 20 feet in width. Trouble is experienced with water, and operations will have to be discontinued until pumping facilities can be provided.

Placer properties of the Cow Creek G. M. Co., south of Baker City, are being fixed for the season's run and will soon begin operations. Five hundred feet of new flume has been put in and a more plentiful supply of water is

expected than was thought probable earlier in the season. Three giants will be worked.

#### Jackson County.

E. D. Briggs of Ashland has a bond on the Golden Wedge, on Galice creek, from Thein Bros. for \$15,000. Considerable development has been done and a 2-stamp prospecting mill is on the group. The new owners intend doing a large amount of work on the property immediately, and expect to erect a larger mill at an early date.

Shipments of from \$800 to \$2000 in dust and nuggets have been made regularly every week through the Jackson County Bank at Medford from the output of the Champlin dredger on Fooths creek. The dredger has made but a slight showing as yet on the vast acreage of ground it has available on Fooths creek, and will operate winter and summer, the water of Fooths creek being sufficiently high to float the machine by the system of wing dams placed below it. At present the dredger is closed down to change power from steam to electricity, the poles and wires having been strung from the power plant of the Condor Water & Power Co. at Gold Ray.

#### Josephine County.

The Bybee quartz mine on Rogue river, 5 miles below Galice, has been purchased from Savage Bros. by E. Cassidy of Bellingham, Wash. The old workings will be reopened.

Superintendent R. N. Bishop of the Greenback M. Co. and Martha M. Co. says the recent find at the Greenback was made on the 500, 700 and 900-foot levels, and at the point now reached by the drifts the ledge shows a width of 21 feet of ore carrying good values. At the Martha mine, no large ore body has been found. Development will be continued with a double shift, men and power drills until the ledge is fully explored.

The Royal group of Galice is being operated by J. R. Harvey. Two giants are working under a pressure of 510 feet. The bank has a height of about 100 feet and carries gold from the surface to the bedrock. Few boulders are met, but the ground is compact, necessitating the use of a strong pressure behind the giants. Considerable powder is also used to loosen the ground and facilitate working. The mine has been in operation for forty years, and as yet, in comparing the ground worked with that which remains, only a beginning has been made. Since the mine has been operating under the present management, it has been improved in its equipment. The ditches have been enlarged and the pipe renewed with strength sufficient to withstand the whole pressure of 500 feet.

The Michigan M. & M. Co. is developing properties on Applegate river, south of Grant's Pass. Buildings, shops, quarters and a mill are under construction. Power will be supplied by a 100 H. P. boiler and engine. Separators, vanners and a steam hoist, capable of developing the mine to a depth of 2000 feet, will be a part of the equipment. The work is done under the superintendence of W. T. Perry. The big Royal hydraulic mines of Galice are being worked with 2 giants under 510-foot pressure. J. Harvey is manager. The banks on the Rocky Gulch channel, where operations are under way on the Royal group this season, are 100 feet high and carry good values all the way down. Dumpage is over a sheer bank, 200 feet into Rogue river.

#### Lane County.

In the Bohemia district the Crystal Con. Co. is getting out timber for the mine and surface buildings. Manager F. D. Wheeler is at the mine.

## SOUTH DAKOTA.

#### Custer County.

The Gladiator Con. M. & M. Co. will build a mill on the Gold Fish mine, near Custer. J. B. Goode of St. Louis is interested.

#### Lawrence County.

On Deadwood gulch,  $\frac{1}{2}$  mile from Lead City, the Hidden Treasure Co. will continue its shaft from the 170 to the 500-foot level.

The Mining Review reports that everything has been shut down at the Clover Leaf mine at Roubaix, except the pumps, pending the completion of plans for a reorganization of the company and an increase of the capital stock. A special meeting of the stockholders of the company has been called for April 10th, at which time a vote will be taken on the proposition to increase the capital stock from \$1,200,000 to \$2,500,000. The par value of the shares will be reduced from \$100 to \$1 each. The company will proceed to double the capacity of its mill by the addition of sixty stamps, sink the shaft to the 1000-foot level, or 300 feet below the present lowest workings, complete the system of damming and transporting Elk creek around the property, and in other ways prepare for enlarging operations in all departments.

The Ohio-Beaver Creek M., M. & Dev. Co. is contemplating building a cyanide plant in the Nigger Hill district. T. C. Lentz of Columbus, Ohio, is president and treasurer; F. L. Stein, secretary; D. Clark of Tinton, general manager, and W. Watson of Tinton, superintendent.

The Rex G. M. Co. has re-elected the following officers: President, Dr. J. A. Steele of Minneapolis, Minn.; vice-president, M. B. Copeland of Omaha, Neb.; treasurer, J. J. Morrow, Lead, S. D.; secretary, A. C. Davis, Lead, S. D.; general manager, John Gilroy. The Rex company's property is 3 miles southwest of Lead City, on Whitewood creek. The principal work of development has been confined to a shaft near the center of the ground. This shaft has been sunk 145 feet and a crosscut driven 500 feet. There are two plans under consideration, namely, to crosscut 500 feet in a northerly direction, and to sink the shaft another 100 feet before doing further lateral exploration. The mine is equipped with a gasoline hoisting engine and air compressor, and pumps have been placed in the mine sufficient in power to handle all the water.

The Wasp No. 2 M. Co., working 2 miles south of Lead City on Yellow creek, reports that, in 1904, 42,042 tons of ore were crushed and treated. The average heads were \$3266; average tails, \$1.15; per cent extraction 67.8. During the year the company paid 16 cents

per share dividend, or \$23,664. The net profit for the year was \$32,189.81. The average cost of mining and milling, which includes all expenses of every kind, such as taxes, insurance, etc., was \$1.76.

The Golden Elk M. Co. will put in machinery to develop their property in the Nigger Hill district. F. E. Wharton of Lead is secretary.

#### Pennington County.

The Ivanhoe Co. at Keystone will resume sinking in its shaft, which is down 100 feet.—F. Groch is making a cyanide test on the ores of the Bismarck mine at Keystone.

The main shaft of the Antler mine is down 30 feet. The shaft is being sunk to a depth of 75 feet, where a drift will be run on the vein to explore the ore shoot at that depth. The mine is on the Burlington railway, 4 miles north of Hill City, and is owned by the Burlington Gold M. Co. H. L. Jones of Hill City is the manager.

A. Anderson is putting a steam hoisting and pumping plant on the Canton mine at Hill City. He intends to put a small test mill on the property.

### UTAH.

#### Juab County.

The shaft at the Victoria mine in North Tintic is down 175 feet and sinking will be continued to the 400-foot level. R. S. Robertson is superintendent.—The force at the McKinley property at Eureka is making rapid progress in the development of the mine. The tunnel is in 500 feet. A depth of over 300 feet has been attained and indications point to the close proximity of an ore body.—The Brooklyn property at Silver City has been producing some good ore, which carries silver, gold, lead and copper. Work is being carried on by a whim at a depth of 200 feet.—Work at the Black Jack mine has been suspended.—The dump at the Tesora mine is being worked by Chas. Boyd and Wm. Owens.

#### Salt Lake County.

The Boston Con. of Bingham, according to Manager M. M. Johnson, is shipping to the furnaces of the Bingham smelter an average of 150 tons of ore daily.

H. M. Adkinson, manager of the New England G. & C. Co.'s mines near Bingham, expects to start the mill about April 1, when water is available. Development is being carried on with machine drills in the mine. President D. W. Williams is expected to visit the mine.

Manager R. H. Channing, Jr., of the Utah Con. M. Co. at Bingham, has men at work on the proposed plant designed by F. Meyer for the abatement of the smoke nuisance. It is the intention to install a pumping plant and water will be obtained from the Jordan river. In connection with the power plant, additional boilers have been installed. About 10,000 gallons per minute of water will be required in the operation of the plant. After collecting the gases, the poison-laden waters will be conveyed away from the banks of the Jordan to a point where they will do no damage.

The aerial tramway system which the Continental Alta Mines & Smelters Co. has installed in the Little Cottonwood mining district at a cost of \$150,000, is nearly completed. The upper 2½ miles of the line, including the terminals, etc., is ready, while on the lower end men are stringing the buckets, tightening the ropes and putting on the finishing touches. It is to connect the company's mines at Alta with the mill on Tanner's Flat. It is equipped with what is stated to be the longest single steel wire rope ever strung along a line of tramway towers. This carrying rope is 10 miles long, and to it are attached the bucket conveyors. H. M. Crowther is manager.

The Tiawauke mines at Bingham have been bought by a company of which L. A. Jeffs of Salt Lake City is president. C. F. Mairs of New York is secretary and treasurer.—The Butler-Liberal at Bingham is to be equipped with a hoist, air compressor, boiler and other machinery by Manager A. L. Jacobs. The air compressor will be of 65 H. P. and will be located at the shaft. A 50 H. P. hoist has been ordered. Its lifting capacity will be 4000 pounds, and it will be equipped with cages.

A 100-ton concentrator is to be built on the West Jordan by G. K. Fischer to treat the second-class lead ore of the Jordan mines at Bingham.

#### Summit County.

At a recent annual meeting of the Daly-West M. Co. held in Denver, Colo., the financial report submitted showed a cash reserve on hand of \$284,148.45. The total receipts from all sources during the year was \$2,280,139.75, as against \$2,643,747.51 during 1903, a decrease of \$363,607.77. From the sale of ores and concentrates the company received during the year \$1,804,672.83. The concentrates and ore were both worth more per ton than they were in 1903, the better work of the mill resulting in concentrates worth \$4.10 per ton more, on the average, than they were during the year previous. Of the regular grade of crude ore 28,355 dry tons were shipped. It contained 1,023,821 pounds of copper, 11,335,964 pounds of lead, 1066.56 ounces gold and 1,578,924 ounces of silver, which sold for \$885,169.30. During the time the Quincy works were operated 14,440 tons of ore, carrying 450,452 pounds of copper, 4,547,258 pounds of lead, 693.33 ounces gold and 625,158 ounces of silver, were sold, for \$305,600.75. The concentrates produced amounted to 15,207 dry tons, containing 541,340 pounds of copper, 9,616,557 pounds of lead, 607.88 ounces gold and 848,652 ounces silver, which sold for \$605,738.65. A new product, known as mill crude, from the sorting belts introduced a few months ago, amounted to 267 tons. This ore carried 7382 pounds of copper, 151,665 pounds of lead, 9.59 ounces gold and 11,490 ounces silver, and sold for \$8,164.13, or \$30.58 per ton net. The concentrates brought \$39.83 per ton, the Quincy crude \$21.16 and the regular crude \$31.22 per ton. The dividends paid during the year aggregated \$1,044,000, making the total to date \$4,635,000, and, the statement says, is practically 50% of the mine's total earnings, which aggregate \$8,955,512.97. All this, excepting about \$336,000, has been taken out of the mine during the past six years. Compared to a year ago the cash reserve shows that it lacks just \$170,847.83 of being as much as stated in the report issued at that time.

#### Tooele County.

The Con. Mercur G. M. Co. has leased the Manning mill at Manning to Glazier & Brisco, who will operate it on ore from the dump.

Connection between the long drain tunnel with which the properties of the Honerine M. Co. at Stockton have been undermined and the new shaft through which the ore is to be dropped into the avenue below, and delivered to the mill without, has been made and the management will begin the delivery of ore through that outlet.

#### Utah County.

At Provo the Garden City M. Co. has completed the chute to carry the ore 1200 feet from the upper tunnel to the bottom of the canyon, where it will be loaded on wagons and taken to the railroad. Work is progressing steadily on the lower tunnel, 300 feet below the upper tunnel.

In the American Fork canyon, the Wyoming mine will resume operations about the middle of March, when the shipping of ore will also commence. During the month that the Wyoming was closed down, a small force has been driving a tunnel which, it is expected, will tap the large ore body of the Wyoming 200 feet lower than any of its present workings. This will facilitate the handling of the ore. Miners are at work on the Shamrock property in American Fork canyon, on the Millar hill, near the Wyoming mine.—The operators of the Bog mine are in 275 feet on the 500-foot tunnel which they are running under Alta peak.

The Dutchman M. Co. will resume operations and sink a 500-foot shaft.

### WASHINGTON.

#### Okanogan County.

Henry Bahrs, manager of the Copper World Extension M. Co. at Loomis, says that he will sink the shaft to a depth of 500 feet and open up levels every 100 feet by drifting and crosscutting on the vein. He has ordered a 40 H. P. steam hoist, an 80 H. P. boiler, a 50 H. P. air compressor and three drills, a 5 H. P. suction fan, wooden tanks, piping and general equipment.

#### Snohomish County.

The Sultan River Placer M. Co. is to work its ground near Monroe under the management of W. R. Menzies of Everett.—The Index Miner reports that the addition to the Bunker Hill concentrator is about completed. One standard Wilfley concentrating table, a Wilfley bed for the slimer now in use and a dynamo will be put in. This will make three Wilfley tables in all in the mill. A generator will be installed at the power house and motors put in at the mill to run the concentrating machinery. This will give electric lights in the various tunnels. V. V. Clark, the superintendent of the mine, and A. W. Sales of the Mine & Smelter Supply Co. of Denver, Colo., have patented a process for the magnetic extraction of ore by the wet process by placing magnets on the Wilfley or other tables, thus drawing the iron to one side and allowing the copper concentration to take place simultaneously. This is designed to evade the drying of the ores or concentrates in a dry kiln.

#### Stevens County.

The channeler and other machinery for the Chewelah Marble Co., whose property consists of eighty acres of fine marble on Deep creek, near Northport, is being moved to the quarry preparatory to commencing operations on a large scale when Manager Hanke arrives.

### WYOMING.

The report of H. C. Beeler, State Geologist of Wyoming, shows the mineral production of Wyoming for 1904 to be 4,220,000 pounds of copper, \$42,000 in gold, 10,500 ounces of silver, 250,000 long tons iron ore and 4,996,828 short tons coal. A majority of the copper mined in the State was smelted there. The coal mines employed 9177 men.

### FOREIGN.

#### AUSTRALIA.

##### New South Wales

The mineral output of New South Wales for 1904 was valued at £6,402,558, as compared with £6,116,254 in 1903. The number of men employed was 37,837, as compared with 37,559 in 1903. The year's gold yield was 269,778 ounces fine, valued at £1,146,109, being an increase, as compared with the previous year, of 15,557 ounces. The silver output is valued at £2,249,482, being an increase of £622,906. The copper output is valued at £420,387, being a decrease of £42,253. The tin output is valued at £184,785, the largest for fifteen years. The coal output was 6,019,809 tons, valued at £1,994,952, being a decrease of 335,037 tons.

### BRITISH COLUMBIA.

The new Haberlin converter is being tried experimentally by the American Smelting & Refining Co. at its Pueblo, Colo., plant. The converter for the Sullivan is designed to reduce the sulphur and facilitate the free extraction of the zinc. The crude ore runs 20% sulphur. It is crushed coarse and is roasted in a revolving machine to cut down the sulphur charge to 8%, then further converted by a hot blast which heats the ore almost to fusion and cuts down the sulphur charge to 4%. The ore instead of being reduced to fine granules, is left in good sized pieces like coke, and the removal of the sulphur leaves air passages all through its texture. It is fed into the smelting furnace without the expense of briquetting. In the smelter furnace fusion is secured with speed as the blast is swept right through the porous ore. There are only two products from the smelter—the silver-lead bullion and the iron-zinc-sulphur slag. The third product—a sort of middlings, made from slag mixed with lead—is avoided. There is a reserve of ore in the Sullivan mine that runs 33% in lead and 14 ounces in silver. Superintendent Weeks is in charge of the smelter. The Sullivan Group Co. is controlled by C. Sweeney, G. Turner and the Federal Mining & Smelting Co.

The tonnage from the dozen Boundary shippers and treatment at three district smelters for last week was: Granby mines to Granby smelter, 9750 tons; Mother

Lode to British Columbia Copper smelter, 2874; Brooklyn to Montreal & Boston smelter, 2996; Rawhide to Montreal & Boston smelter, 2091; Sunset to Montreal & Boston smelter, 30; Mountain Rose to Montreal & Boston smelter, 132; Emma to Nelson and British Columbia Copper smelter, 363; Oro Denoro to Granby smelter, 66; Senator to Granby smelter, 264; Providence to Trail smelter, 60; Last Chance to Montreal & Boston smelter, 55; E. P. U. to Trail smelter, 20; total for week, 19,511; total for year, 129,040 tons. Boundary district smelters this week treated ore as follows: Granby smelter, 10,536 tons; British Columbia Copper smelter, 3838 tons; Montreal & Boston smelter, 6195 tons; total for week, 20,679 tons, or a total of 130,597 tons for the year.

At the mine, near Kimberley, 35 men are at work. The tramway 6300 feet long, connecting the mine with the Canadian Pacific railway, is running, and ore is being moved. The bins are complete, and ore is being crushed; a car of siliceous ore is daily received from the Quilp mine Republic, Wash. The Quilp has a contract with the Sullivan for supplying all the siliceous ores required.

Lime ore for flux is being received from the Hunter V mine near Ymir. It is a low grade silver product.

At Poplar, the Pluto mine ore is being sacked for shipment to the smelter. The quartz in the vein is 4½ feet in width, the schist in the ledge is 25 feet in width, both carrying gold values. The richer ore in the quartz is sent to the smelter or milled. The schist will pay to run through. Dr. Gilbert is in London to form a company and raise money to build a stamp mill at Poplar for reducing the ore of the Marquis and Gilbert group.

#### Atlin District.

The Mining Exchange reports that this winter 250 men are drifting; 150 on Spruce creek and most of the rest on Pine creek, Gold Run, or Boulder; but a few on Ruby, Wright, Birch and McKee. The longest tunnel on Spruce creek is that of the Fleming partnership. It is driven into the left bench 500 feet. At Boulder Creek, Black and Grant, working a "lay" from the French Co., cleaned up \$13,400 between the middle of October and Christmas. Their main drift is 900 feet long, with a face of 40 feet. They employ 40 men. The total output of Atlin up to the close of navigation exceeded \$500,000. Last year dredging was started; this year will witness the introduction of steam shovels, one to operate on Tar Flat, Pine creek; the other on Spruce creek below Discovery claim. A third shovel may be brought in for McKee creek in order to load pay gravel from the pits of the Hydraulic Co. into electric cars, which will transport the gravel to the lake at the mouth of the creek that it may be there washed. Another dredge is well under way, and an electric pole line 7½ miles long has been constructed, a basin excavated, and the framework commenced. It will be a 7½-foot open-connected dredge, and will be placed below the Blue Canyon on Spruce creek. One of the chief difficulties that the Gold Commissioner has to adjust is the apportioning of dumpage ground to creek miners and benchers on Spruce. That difficulty will be removed when the bed-rock flume that is now contemplated is completed. It will be built from the falls upstream and will likely be on a scale to carry all the water of the creek. In 1905, the following hydraulic companies will continue operations: Pine Creek Power Co., North Columbia Gold M. Co., Atlin & Willow Creek M. Co., on Pine creek; Spruce Creek Power Co. and Columbia Hydraulic Co., on Spruce creek; Amalgamated McKee Creek M. Co. on McKee creek; Atlin Lake Co., on Birch creek; Societe Miniere de la Colombie Britannique, on Boulder creek. Development will be continued on several quartz properties, especially on the "Beavis," where, it is reported, machinery will soon be installed.

#### Boundary District.

Superintendent Collins of the Montreal & Boston Con. mines is making a success of using black powder in the glory hole operations at the Rawhide mine, the result being an increased tonnage of ore broken at the minimum of expense. The plan used is similar to that on railway construction rock work, and M. J. Burns is in charge of the blasting operations at the Rawhide.

The Le Roi concentrator on the Black Bear ground will be in operation within ninety days. The ground dimensions of the structure are 40x120 feet, and it will be arranged, like all other mills of this character, so that the ore will fall by gravity from one process to the other. The capacity will be 150 tons of ore a day. It is thought the best results will be obtained by water concentration.

The following resolution has been passed by the Rossland Board of Trade:

Resolved, That this board views with alarm the proposal to introduce an eight-hour law for smeltermen, and is of the opinion that if the proposed legislation is passed it will tend to transfer to the United States the smelting of British Columbia ores, and thus deprive Canadian workmen of being employed in Canadian smelters, and that this resolution be telegraphed to the premier.

The Le Roi M. Co. at Rossland cables its London office: "Shipped from the mine to Northport during the past month 10,058 tons of specially selected ore, containing 4813 ounces of gold, 4286 ounces of silver and 225,600 pounds of copper. Estimated profits on this ore after deducting cost of mining, smelting, realization and depreciation, \$27,000. Expenditure on development work during the month, \$8750. Development of the mine continues to be satisfactory, principally on the 900 and 1450-foot levels."

The Great Northern Railway is hauling ore from Phoenix to Grand Forks. The company has erected big ore bunkers and is using steel ore cars. About 300 tons of Granby ore is hauled daily from No. 3 tunnel level of the Granby, brought to the bunkers by three electric locomotives.

It is reported that development on the Nellie Cotton group, adjoining the Granby mines, will be started by April 1.—B. Perkins has started shipping ore from the Riverside group, Kettle river, 3 miles from Rock creek.—J. W. Nelson has received the smelter returns of a 22-ton ore shipment from the Rambler mine, west fork of Kettle river. The shipment netted \$73.24 per ton.—D. McIntosh is putting in an 8x10 hoist in the

E. P. U. mine, at Providence, which has been equipped with a 25 H. P. hoiler and a No. 6 Cameron pump.—Two smelters at the Granby smelter, at Greenwood, are now operated with the new electric self-charging apparatus.

Cariboo District.

The Con. Cariboo Hydraulic M. Co.'s profit and loss account for 1904 shows the increase in debt for the season's work amounted to \$27,172.08, the balance at debit being \$51,707.90 against \$24,535.82 on Dec. 31, 1903. The operating expenses per manager's report were \$88,423.75, and the total value of bullion obtained was \$85,936.30, making a direct loss in operating account of \$2,487.45. The accrued interest on the bonds amounted to \$24,000. From Manager J. B. Hohson's report the total operating season was eighty-nine days, and the reasons of scanty precipitations and adverse conditions respecting the molting of the winter snows are again adduced. The total water used amounted to 184,889 inches, which washed 1,327,817 cubic yards of dirt, an average duty of 7 1/2 yards per inch. The total gold recovered from this yardage amounted to \$84,866.21, or an average yield of 6.38 cents per cubic yard. The average cost per cubic yard was 6 1/5 cents, making the loss per cubic yard on working alone about 3 mills.

Rossland District.

The report of ex-Manager Kirby of the War Eagle Con. M. & Dev. Co. shows that during 1904 the management devoted most of the time to developing the property and placing it on its present footing; 61,064 tons were extracted and disposed of at a profit of \$80,000. The average value per ton was \$12.45. The War Eagle is now in a position to more than double its output of last year. Since the last annual report 2220 feet of headings have been driven. New shoots of high-grade ore have been discovered and blocked out in many directions, and old stopes have been opened.

The number of men employed at the different mines in the Rossland district is as follows: War Eagle, 120; Center Star, 210; Le Roi, 250; Le Roi No. 2, 116; White Bear, 30; Spitzee, 25; Jumho, 25; small properties, 24—total, 800.

Chairman McLean, of the Velvet-Portland company, is expected to arrive at Rossland from London to resume work on the properties of the company and restart the 100-ton concentrating mill. W. M. Thompson, the consulting engineer of the company, is expected to arrive from Mexico.

Slocan District.

The lessees of the Payne mill have contracted with the owners of the Beatrice mine, in the Lardau, to concentrate 1000 tons of ore.—The mill at the Cork mine, on the south fork of Kaslo creek, in the Ainsworth division, is completed. It is expected that a large force will be put to work as soon as P. Maris, the manager of the mine, returns from France.—An option has been given by C. A. McLeod on the Mountain Con. group to M. S. Logan of Nelson for \$67,500. The group consists of the Mountain Con. and Castick claims, on the divide between the south fork of Kaslo creek and Cody.

Southeast Kootenay District.

The Prospector reports that R. B. Durant, placer mine operator at Perry Creek, is preparing to sink a shaft to bedrock near Old Town.—J. Thompson and E. Banks have a shaft down 44 feet. As soon as the bottom deposit of gravel is reached drifts will be started in two directions in search of a rich run of pay gravel.—J. Henneberry has commenced permanent work on his placer lease on Perry creek. A hoisting plant and Cameron sinking pump has been put in. A shaft is down 40 feet.—Collins & Armstrong are drifting on a bench above Old Town and are in 60 feet.—M. Shilling is drifting for an old channel near Sawmill creek.

HONDURAS.

(Special Correspondence).—At San Juancito, 75 miles from the Pacific coast of Honduras, the New York & Honduras Rosario M. Co. has replaced primitive methods of mining by the most modern. According to the company's report for the year ending Sept. 30, 1904, an average of 861 men were employed. During the year 5264 feet of drift and crosscut and 1443 feet of raises were driven. Two continuous chutes, passing 1500 feet through the whole vertical extension of the mine, have been completed, so that the entire output is drawn from the lowermost adit. The cost of mining averaged \$13.33 per ton, of sorting 58 cents and of aerial transportation to the mill 42 cents. The ore is crushed in a stamp mill, amalgamated and concentrated. It has been the practice at the Rosario to treat the ore by pan amalgamation for years; but it is now known that a larger net result can be obtained by simple plate amalgamation and concentration. The Rosario is the most important mine at present operating in Honduras. It has been worked steadily for twenty-five years by the American company, after having been worked in primitive manner by the native miners for years prior to the purchase by the present owners. The price paid for the property, including several buildings, is stated to have been but \$11 gold. Nearly \$400,000 was then expended in development and equipment, and during the first four years of its operation by the American company less than \$10,000 in bullion was shipped to New York. A new manager was appointed, and during the year ending June, 1885, over \$600,000 was shipped in silver-gold bullion. Since that date the mine has been a steady but somewhat variable producer. It is 18 miles by trail from Tegucigalpa, the capital. There are no roads, except those owned by the company and made during the early period, and extending from the mill to the mine; cost, \$20,000. The cost of packing ore over this road was \$4.50 per ton. In 1885 the first aerial tramway was built, and the cost of transportation by this method is now said to be 42 cents per ton. The mine is located on a high, steep mountain side, cut by rugged canyons. The mill and town of San Juancito are located in a valley-like widening where a branch canyon joins the main canyon. The vein, which is a fissure, often showing comb structure, varies from 3 to 15 feet in width. The country rocks are a dense, black massive to slaty rock, traversed by veinlets of calcite. It is extremely hard and development work in rock of this character is expensive. This slate is intruded by an igneous rock, variously described

as syenite, rhyolite, etc. The vein courses through both slate and eruptive rock without noticeable change in the value or character of the ore. The ruins of the old reverberatory and other furnaces and metallurgical works may still be seen in the canyon below the village of San Juancito. With proper transportation facilities, there are many other mines in Honduras which would prove profitable under experienced management. There are numerous gold-bearing veins in the department of Olancho on which only superficial development has been done, and silver mines, both ancient and newly discovered, are numerous in the Republic.

Puerto Cortez, Feb. 16.

PERU.

The following is official and shows the duties imposed upon electric and gas equipments imported into the republic of Peru:

DESCRIPTION.	Minimum Value Per 2 1/2 Pounds.	Rate of Duty, %.	Duty Per 2 1/2 Pounds.
General supplies, such as circuit breakers and fuses, circuit makers, keys, plugs, and electric switches of all kinds and types having china bases and tops.	\$ 60	40 24	
Do, with china bases and metal tops.	1 00	40 40	
Do, with slate or marble bases, with or without tops.	1 50	40 60	
Glass insulators, gross weight.	07	40 28	
Insulators, of clay and pottery ware, not over 0.03 meter in circumference, with or without pins, gross weight.	30	40 12	

MEXICO.

Returns are slow from the mining districts of Mexico; in consequence it is impossible to give an accurate report on the mineral production of the republic for 1904. Semi-official information, however, gives the following report of production for 1904. Silver is quoted at its coinage value, not at its commercial value, as in the United States:

Silver.....	\$82,200,000
Gold.....	32,500,000
Copper.....	19,700,000
Lead.....	6,000,000
Total.....	\$140,400,000

During the three years ending Dec. 31, 1903, Mexico exported more than \$31,000,000 in gold, more than \$125,000,000 in silver and nearly \$400,000 in other metals.

A mining company recently petitioned the secretary of hacienda to exempt from the coinage and assay taxes dross and residues and other second-class metallurgical products from smelters, which do not assay over 250 grams silver or ten grams gold per ton, says the Investor. The secretary has issued an order exempting those products and notice thereof has been sent to all custom house collectors.

Chihuahua.

The Vaticana M. Co., owning the Papa and Vaticana mines in the Almoleva district, has incorporated with J. F. Flynn president, H. L. Warne secretary and G. A. Burr manager. The properties are being developed and an 8-foot vein of shipping ore has been opened that runs from 1500 to 2000 grams of silver, 8 to 10 grams in gold, 2% copper and 15% to 30% lead.

The Cia. Metalurgica de Torreón, owner of the Torreón smelter, at its recent annual meeting, reported the yearly profits for 1904 amounted to \$629,279.50, equal to 18% of the capital of \$3,500,000 invested. The general meeting declared a dividend of \$14 per share and \$12 for each share of common stock, payable April 30 next. In the year 1904 the total tonnage smelted was 201,612 tons of ore and fluxes. Two more furnaces were added to the plant, and now the Torreón smelter has in constant operation eight furnaces. Consequently, the capacity is 80% as large as the plant of No. 3 smelter in Monterey of the A. S. & R. Co. The Torreón Co. owns and controls 130,000 tons of lead ore, blocked out in the Cahrillas mine, near Saltillo, on the National Railroad; San Diego mine, in Santa Barbara, Chihuahua; Las Adargas, near Jimenez, and also in the Valadara mine, Aztec and Carbonato properties adjoining Valadara.

Coahuila.

A company composed of British and German capitalists has been formed to work a recently discovered coal field near Sabinas. The principal vein is from 7 to 8 feet wide, and underlies an area of 15,000 acres. The new coal fields is 7 1/2 miles from the Mexican International railway. Coahuila already produces 3000 tons of coal and 1500 tons of coke daily.

Michoacan.

The Rothschilds are reported investigating and negotiating for large copper properties in this State in the Inguaran district. Should the report be favorable it is expected that a railroad will be constructed from the mines to the present main line of the Central or to Zihuatanejo on the Pacific coast. The sale of these mines depends upon the output and also upon the facility for construction of a railroad and it has been estimated that the mines can produce 18,000 tons annually.

Monterey.

The Laredo M. & S. Co. are working La Mina B in the Galeana district, near Monterey, under the management of W. H. Banks. The 6-mile wagon road from the mines to Galeana is being completed. C. G. Brewster is president of the company at Laredo, Texas.

Sonora.

The Wisconsin-Mexico M. Co., of Milwaukee, Wis., operating the Plomosa, Iris and Oh'Gee mines, near Huapac, 125 miles north of Hermosillo, on the Sonora river, is constructing its stamp mill, for which all machinery is on the ground and the work progressing under direction of R. Graham. When finished the company will have a complete equipment, having already a thirty-ton smelter, briquetting machines, etc. Development of the mines is also going on, and within sixty days the company should be ready to commence treating their ores.

S. Crump says the Yaqui war is of greater proportions than is commonly supposed. Recently a number of Mexicans were killed by the Indians south of Arizpe, and it

is now impossible to get Mexicans to go into the hostile country on any pretext. A short time before the Indians took the war path he saw about 100. Most of the men had 30-30 Winchesters and cartridges. Mr. Crump had a 30-30 and a belt full of ammunition; the Indians offered him several good ponies for 100 cartridges; he refused to trade and they offered him a piece of land for the ammunition, but he would not let his cartridges go.

Nogales reports that the mining industry to the south of that city is paralyzed on account of fear of the depredating Yaquis. The Benson Press notes that many mining men who came out of Sonora on account of the Indian scare, or had turned back from their trip there, were now making examination of the mining districts on this side of the international line in Arizona.

SOUTH AFRICA.

The December gold production of South Africa shows: Number of mines making returns: Rand, 61 (5555 stamps); Heidelberg, 1 (50 stamps); Barberton, 5 (145 stamps); Klerksdorp, 1 (— stamps); Lydenburg, 2 (70 stamps); total, 69 (5835 stamps).

Personal.

R. A. PARKER has returned from California to Denver, Colo.

D. C. BAKER of Deadwood, S. D., is in New York City on mining business.

C. E. FINNEY has returned from Colorado Springs, Colo., to New York City.

WILLIAM P. MILLER, JR., is in the State of Guerrero, Mexico, examining placers.

G. WINGFIELD has been appointed manager Booth G. M. Co. at Tonopah, Nev.

ALEX. MOFFATT will resign as superintendent Ontario mill at Park City, Summit county, Utah.

JAMES PRYOR of Jerome, Ariz., is engineer Oro Grande mines, southeast of Martinez, Ariz.

J. A. BUTCHART, secretary and treasurer Ophir Tunnel Co., is at Ophir, Utah, from Duluth, Minn.

A. F. HOLDEN of Salt Lake City, Utah, has been examining the Mammoth mine, in Shasta county, Cal.

C. C. JEWELL has been made manager Free Gold M. & M. Co. at White Oaks, Lincoln county, New Mexico.

R. N. DICKMAN of Dickman, Mackenzie & Potter of Chicago, Ill., is in Arizona examining mining properties.

C. W. PLATT of Prescott, Ariz., is superintendent Monarch M. & S. Co., 12 miles northeast of Wickenburg, Ariz.

W. J. CRAIG has resigned as superintendent Yampa mines at Bingham, Utah, and will look after private interests.

JOHN STALLINGS, Lincoln mine, near Pearl, Idaho, has been examining mines at Good Springs, Lincoln county, Nev.

PIERRE WIBAUX, president Clover Leaf G. M. Co., at Roubaix, S. D., has returned to South Dakota from Paris, France.

J. T. LANGFORD of Stockton has been appointed superintendent Rio Vista copper mine near Fairplay, El Dorado county, Cal.

P. J. MINITER, formerly chief assay department for the Government at Deadwood, S. D., is examining mines on Cherry creek, near Prescott, Ariz.

ARTHUR H. BUCK has resigned as superintendent N. Y. & Honduras R. M. Co., San Juancito, Honduras, C. A., and will return to Denver, Colo.

C. MAUNDER has been appointed superintendent California & Nevada M. Co., adjoining the Kane Wonder mine in the Funeral range, Ballarat, Cal.

M. M. HOWE, general manager for the Senator M. Co., has returned to Breckenridge, Colo., from a business trip to Boston, New York and Washington.

J. C. ERMAN has resigned as engineer in charge Starlight mines at San Carlos, Ariz., to become manager Keystone copper mines at Globe, Ariz.

HORACE F. BROWN of San Francisco, Cal., has gone to Pittsburg, Pa., to continue his experiments commenced there last summer in the making of steel by a new process.

C. A. PARSONS, manager Mercantile Finance Co., Chicago, Ill., is in San Francisco, Cal. His company has recently acquired the Moose creek placers at New-some, Idaho, which he will operate this season.

ROBT. FORSYTH has been elected president Union Iron Works, San Francisco, Cal. Mr. Forsyth has been engineer in chief of the Union Iron Works for twenty years. Geo. Fredericks has been elected vice-president, Chas. N. Champion secretary, H. S. Snyder treasurer.

RUFUS BUCK, E. M., who is engaged in mining engineering work near Dawson, Yukon Territory, is in San Francisco, Cal., on a visit. He returns to the north as soon as transportation opens in the spring to continue the extensive work of ditch and flume construction in which he was engaged last season.

## Commercial Paragraphs.

H. L. SINCLAIR, manager of the Denver, Colo., branch of the Hardsocg Wonder Drill Co., is spending some time at the works, Ottumwa, Iowa.

J. A. THOMAS succeeds F. H. Johnson in the management of the mining department of the Fulton Iron Works, whose new office address is 17 First street, San Francisco, Cal.

W. A. HENDRYX, manager of the Hendryx Electro Cyanide Co., is installing a testing plant at 1738 Broadway, Denver, Colo., where he will make tests by the Hendryx process.

B. A. SCHRODER, for some time attached to the St. Louis office of the Crocker-Wheeler Co., has been placed in charge of the New Orleans office of the company, succeeding P. Field, who has been transferred to the Boston office.

CYANIDE TANKS and equipment to increase the capacity of the cyanide plant of the Black Range M. Co., Magdalena, N. M., from 50 tons to 150 tons daily capacity are being furnished by The S. H. Supply Co. of Denver, Colo.

THE first of a series of bulletins from the Ingersoll-Sergeant Drill Co., 26 Cortlandt St., New York, describes labor-saving tools operated by compressed air. No. 2000 describes the Macdonald rivet forge. The series will be sent to any address.

H. L. WOOLFENDEN, manager of the Denver branch of the Gilbert Wilkes Co., has resigned and in future will have charge of the Bullock electrical machinery of the Allis-Chalmers Co. and will be associated with R. B. McConney, manager of the Allis-Chalmers Co. Denver, Colo., branch, with offices at 1649 Tremont St.

THE Mammoth Copper M. Co. of Salt Lake City, Utah, has just placed an order with the Westinghouse Electric & Manufacturing Co. for a total of nearly 800 H. P. in induction motors of different sizes, together with a motor-generator set, transformers, switchboard and three mining locomotives. The motors will operate on three-phase, 2000-volt circuits.

## Books Received.

The future importance of New Mexico as a mining country is ably set forth in "New Mexico Mines and Minerals" by F. A. Jones. The book gives a complete account of the mining history, mineral resources and known geology of New Mexico's ore deposits. In a general way it presents much of interest and value. Being somewhat of a popular treatise, it omits some details as to mine management and working that is of interest to the mining fraternity. Its value as a reference book would be greatly enhanced by an index. It is published by F. A. Jones, Santa Fe, New Mexico, for \$2, and will be sent postpaid by the MINING AND SCIENTIFIC PRESS upon receipt of price.

The U. S. Geological Survey Bulletin 261, "Preliminary Report on the Operations of the Coal Testing Plant at the Louisiana Purchase Exposition," gives an account of the various tests and results of a number of coals. It is of interest in describing methods and giving properties of coal tested. Bulletin 242, on the "Geology of the Hudson Valley Between the Hoosic and the Kinderhook," by T. N. Dale, is a valuable contribution to the structural geology of New York State. Bulletin 288, "The Economic Geology of the Iowa Quadrangle, Kansas," by G. I. Adams, E. Haworth and W. R. Crane, gives an interesting account of the oil and gas occurrences of southeastern Kansas. The rock formations are interstratified shales, sandstones and limestones, which have a northeast-southwest strike. The sandstones are the principal oil and gas reservoirs. The occurrence of the oil and gas points to an organic origin. The gas is largely used in smelting zinc ores, of which a brief account is given. Cement, lime and clay are economic products of the region.

No engineer of to-day can do his work without a thorough grounding in the principles of mechanics. "Elements of Mechanics," by Mansfield Merriman, gives an elementary but concise introduction to these principles. The book is clearly and logically written and requires only a knowledge of plain geometry, elementary algebra and plane trigonometry for intelligent study. It is intended as an introduction to analytic and applied mechanics. It would seem that the author has taken the mathematical rather than the physical view of the subject. Naturally the subject offers little field for originality in its elementary phases and many books have already appeared containing essentially the same subject matter; the chief reason for its appearance seems to be that it omits much of the higher mathematics and brings the subject within the range of the less advanced student. The author evidently does not respect poetic license, inasmuch as he presents a problem to analyze the athletic feats of Hiawatha. The book is published by John Wiley & Sons, 43 East Nineteenth street, New York City, for \$1 and will be sent postpaid by the MINING AND SCIENTIFIC PRESS upon receipt of price.

The appearance of a fourth edition of "A Manual of Mining," by M. C. Ihseng, is in itself a good recommendation for this work. The former editions have long served the purpose of giving an intelligible account of mining methods, and the addition of 150 pages brings this pretty well up to date. No one will ever become a mining man from the mere reading of Ihseng's book or of any other book, but this will give a comprehensive and general idea of the many sides of the subject, that

could otherwise be gained only by years of observation. The parts on methods of mining are lacking in suggestions as to overcoming difficulties in metal mining. The chapters on handling material are applicable either to coal or metal mining, likewise those of pumping. A book of this kind is necessarily a compilation of many works, and while the latest edition contains much that is new, yet it also contains many old illustrations. One wonders if there have been no recent applications of some of the classical methods. On the whole, the book is as good an exponent of American practice as we have and amply repays study. It devotes more space to power and its transmission than is usually done. It is published by John Wiley & Sons, 43 East 19th St., New York City, for \$5, and will be sent post paid by the MINING AND SCIENTIFIC PRESS upon receipt of price.

## Trade Treatises.

Form 35 A from the Ingersoll-Sergeant Drill Co., 26 Cortlandt St., New York, gives that company's latest exemplification of air compressors.

The Westinghouse Electric & Manufacturing Co. of Pittsburgh describes its type F induction motors for variable speed work and its type R direct current motors in sizes from  $\frac{1}{2}$  to 1  $\frac{1}{2}$  H. P. in folders Nos. 4038 and 4039.

## Obituary.

EDWARD HALLAM, aged 22 years, was killed in the Kennedy mine, at Jackson, Cal., on March 6.

G. W. KRAMER, a mining man of Washington, Nevada county, Cal., died of consumption at San Jose, Cal., March 4.

ROLAND C. LUTHER, second vice-president of the Philadelphia & Reading, who as a mining engineer developed silver mines in Nevada from 1875 to 1882, died March 6, aged 59 years, at Pottsville, Pa.

## Latest Market Reports.

SAN FRANCISCO, March 10, 1905.

### METALS.

SILVER.—Per oz., Troy: London, 27 $\frac{1}{2}$ d (standard ounce, 925 fine); New York, har silver, 58 $\frac{1}{2}$ c, refined (1000 fine); San Francisco, 58 $\frac{1}{2}$ c; Mexican dollars, 48 $\frac{1}{2}$ c, San Francisco; 45 $\frac{1}{2}$ c, New York.

COPPER.—New York: Standard, \$15.50; Lake, 1 to 3 casks, \$15.37 $\frac{1}{2}$ @15.50; Electrolytic, 1 to 3 casks, \$15.37 $\frac{1}{2}$ ; Casting, 1 to 3 casks, \$15.25. San Francisco: \$16.00. Mill copper plates, \$17.00; hars, 18@24c. London: £68 3s 9d spot per ton.

Copper shows signs of weakness and prices are a little lower than those quoted last week. The latest quotations, however, are slightly higher than those of a day or two previous.

LEAD.—New York, \$4.60; Salt Lake City, \$3.50; St. Louis, \$4.12 $\frac{1}{2}$ ; San Francisco, \$3.70, carload lots; 4 $\frac{1}{2}$ c 1000 to 4000 lbs.; pipe 6 $\frac{1}{2}$ c, sheet 7, bar 5 $\frac{1}{2}$ c; pig, \$4.85. London: £12 5s  $\frac{1}{2}$  long ton.

SPELTER.—New York, \$6.25; St. Louis, \$6.30; London, £24  $\frac{1}{2}$  ton; San Francisco, ton lots, 6 $\frac{1}{2}$ c; 100-lb lots, 7c.

TIN.—New York, pig, \$28.50@29.00; San Francisco, ton lots, 30c; 500 lbs., 30 $\frac{1}{2}$ c; 200 lbs., 30 $\frac{1}{2}$ c; less, 31c; har tin, 31 $\frac{1}{2}$ c. London, £135 5s.

PLATINUM.—San Francisco, crude, \$18.50  $\frac{1}{2}$  oz.; New York, ingot, \$19.50  $\frac{1}{2}$  Troy oz. Platinum ware, 75@82c  $\frac{1}{2}$  gram.

QUICKSILVER.—New York, \$40.00@41.00, large lots; London, £7 12s 6d; San Francisco, local, \$38.00  $\frac{1}{2}$  flask of 75 lbs.; Denver, \$45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6 $\frac{1}{2}$ c; extra, 17 $\frac{1}{2}$ c; genuine, 31 $\frac{1}{2}$ c; Eclipse, 35c. SOLDER.—Half-and-half, 100-lb. lots, 19.75c; San Francisco, Plumbers', 100-lb. lots, 16.50c.

ZINC.—Metallic, chemically pure,  $\frac{1}{2}$  lb., 50c; dust,  $\frac{1}{2}$  lb., 10c; sulphate,  $\frac{1}{2}$  lb., .04c.

NICKEL.—New York, 55@60c  $\frac{1}{2}$  lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c  $\frac{1}{2}$  lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburgh. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburgh.

### STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$16.85@17.10; gray forge, \$16.85; San Francisco, har, 3c  $\frac{1}{2}$  lb., 3 $\frac{1}{2}$ c in small quantities.

STEEL.—Bessemer billets, Pittsburgh, \$23.00@27.00; open hearth billets, \$23.00@27.00; San Francisco, bar, 7c to 12c  $\frac{1}{2}$  lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6 $\frac{1}{2}$ c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, 1c  $\frac{1}{2}$  lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, 1c per lb. above keg price.

Dry Lead.—In hbls., 1 ton and over, 6 $\frac{1}{2}$ c; do. in kegs, 7c. LUMBER.—(Retail): Pine, ordinary sizes, \$24.00@5.00; extra sizes higher; redwood, \$28.00@30.00; lath, 4 cts, \$4.50@5.00; pickets, \$21.00; shingles, \$2.50 for No. 1 and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00@35.00.

NAILS.—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.55; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d, Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4d and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

LIME.—Santa Cruz, \$1.25 country, \$1.25 city  $\frac{1}{2}$  hbl.

CEMENT.—Imported, \$2.15@2.65  $\frac{1}{2}$  hbl.; California, carload lots, \$2.10 f. o. b. at works; small lots, \$2.40  $\frac{1}{2}$  hbl. in sacks, 4 sacks to hbl., 10c for each sack returned.

### GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 8 $\frac{1}{2}$ c; Hallett's, 8 $\frac{1}{2}$ c; San Francisco, 1000-lb. lots, 9c; 300@500-lb. 9 $\frac{1}{2}$ c; 100-lb. lots, 10 $\frac{1}{2}$ c.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lot, Eastern and foreign: Wallend, \$7.50; Brymbo, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8.00; Cumberland, \$13.00; Cannel, \$8.50; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in hulk, \$13.00 in sacks; Sunnyside, \$8.50, long ton.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15 $\frac{1}{2}$ c; less than one ton, 17 $\frac{1}{2}$ c. No. 1\*, 60%, carload lots, 13 $\frac{1}{2}$ c; less than one ton, 15 $\frac{1}{2}$ c. No. 1\*\*, 50%, carload lots, 11 $\frac{1}{2}$ c; less than one ton, 13 $\frac{1}{2}$ c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9 $\frac{1}{2}$ c; less than one ton, 11 $\frac{1}{2}$ c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg.

CAPS.—3x, \$5.50@6 per 1000; 4x, \$6.50@7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

FUSE.—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s, 11c  $\frac{1}{2}$  set; 14 oz., 40s, 9 $\frac{1}{2}$ c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c  $\frac{1}{2}$  lb.; carloads, 23@23 $\frac{1}{2}$ c; in tins, 30c; soda ash, \$2.00  $\frac{1}{2}$  100 lbs.; hyposulphite of soda, 3@3 $\frac{1}{2}$ c  $\frac{1}{2}$  lb.; caustic soda, in drums, 3@3 $\frac{1}{2}$ c  $\frac{1}{2}$  lb.; Cal. s. soda, hbls., \$1.10@1.20  $\frac{1}{2}$  100 lbs.; sks., 90c@1.00; chloride of potash, 12@13c; nitrate of potash, 6 $\frac{1}{2}$ @7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2 $\frac{1}{2}$ @2 $\frac{1}{2}$ c; powdered sulphur, 2 $\frac{1}{2}$ @2 $\frac{1}{2}$ c; flour sulphur, French, 2 $\frac{1}{2}$ @—c; alum, \$2.00@2.25; California refined, 1 $\frac{1}{2}$ @2c; sulphide of iron, 8c  $\frac{1}{2}$  lb.; copper sulphate, 5 $\frac{1}{2}$ @5 $\frac{1}{2}$ c; chloride of lime, spot, \$2.50@2.75; sulphuric acid, in carboys, 66% B, 1 $\frac{1}{2}$ @2c  $\frac{1}{2}$  lb.; nitric acid, carboys, 8c  $\frac{1}{2}$  lb.

OILS.—Linseed, boiled, hbl., 60c; cs., 65c; raw, hbl., 58c; cs., 63c; Lucol oil, boiled, hbl., 51c; cs., 56c; raw hbl., 49c; cs., 54c. Kerosene—Pearl, per gal., 19c; As, tral, 19c; Star, 19c; Extra Star, 22c; Ecocene, 21c, Elaine, 25c; Water White, in hulk, 12 $\frac{1}{2}$ c; Mineral Seal iron bbls., 18c; wooden bbls., 20c; cs., 24c; Minera; Sperm, cs., 26 $\frac{1}{2}$ c; Deodorized Stove Gasoline, hulk, 16c, do., cs., 22 $\frac{1}{2}$ c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19 $\frac{1}{2}$ c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, hbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 63c; Bleached, do., 57c; Whale Oil, cs., 52@57c.

BORAX.—Concentrated, 6@7c  $\frac{1}{2}$  lb.; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5@6c  $\frac{1}{2}$  lb.; No. 1, 4@5c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c  $\frac{1}{2}$  lb.

MOLYBDENUM.—Best, \$2.75  $\frac{1}{2}$  lb.

CHROMIUM.—90% and over,  $\frac{1}{2}$  lb., 80c.

PHOSPHORUS.—American,  $\frac{1}{2}$  lb., 70c.

SILVER.—Chloride,  $\frac{1}{2}$  oz., 90c@1.00; nitrate, 55c.

RED LEAD.—500 lbs. and over at one purchase,  $\frac{1}{2}$  lb., 7c; less than 500 lbs., 7 $\frac{1}{2}$ c.

MANGANESE.—Per lb., \$2.75.

MAGNESIUM.—Pure, N. Y., \$1.60.

FIRE BRICK.—Domestic, carloads, \$1000, f. o. b., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skewback, \$30.00; circle, \$32.00.

FIRE CLAY.—Domestic,  $\frac{1}{2}$  ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, \$8.50.

## New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR WEEK ENDING FEBRUARY 23, 1905.

783,990.—PUMP—J. Reusher, Seattle, Wash.  
783,773.—BICYCLE SEAT—E. E. Brown, Los Angeles, Cal.  
783,608.—JAR CLOSURE—W. C. Rubles, S. F.  
783,610.—BARREL VENT—M. J. Chaplin, Seattle, Wash.  
783,619.—TREATING SALT—H. C. Coward, Oakland, Cal.  
783,821.—THRESHER FEEDER—A. C. Critchfield, Rosalia, Wash.  
783,624.—ARTIFICIAL FUEL—J. T. Davis, S. F.  
783,686.—NUT LOCK—J. T. Davis, S. F.  
783,699.—BAKE OVEN—A. Edwards, Redlands, Cal.  
783,571.—SEPARATOR—C. Fricks, S. F.  
783,631.—CABLE CLIP—W. Gregor, Barron, Wash.  
783,575.—SEWER FORM—C. Gustafson, Oakland, Cal.  
783,663.—CATTLE GUARD—A. C. Hendryx, Portland, Or.  
783,580.—DESIGN PRINTER—G. A. Herzog, S. F.  
783,657.—TRACK CLEARER—S. F. Hudon, Wenatchee, Wa-h  
783,489.—FEED WATER HEATER—J. M. Keller, Los Angeles, Cal.  
783,531.—LITERARY BOOK—E. Kendall, S. F.  
783,435.—TILING PACKAGES—L. Olson & Peterson, Spokane, Wash.  
783,908.—TRUNK STRAP—Fanny A. Lyman, Seattle, Wash.  
783,647.—ROPE CLIP—B. C. Rhiet, Spokane, Wash.  
783,594.—FLOW—E. J. Rubottom, Felton, Cal.  
784,011.—BALE—A. M. Sheakley, Stockton, Cal.  
784,014.—NUT LOCK—A. P. Steel, Stockton, Cal.  
783,905.—HAME—T. E. Stockford, Leesville, Cal.  
783,711.—TIME SWITCH—C. J. Sullivan, San Jose, Cal.  
784,018.—SUTURE SUPPORT—O. D. Withersee, Los Angeles, Cal.  
783,810.—ARTIFICIAL FUEL—H. R. Woltman, Berkeley, Cal.  
783,919.—GAS BURNER—J. P. Yoho, Seattle, Wash.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

ORE FURNACE.—No. 783,903. Feb. 28, 1905 August Skoog, Shreveport, La. This invention relates to improvements in ore furnaces, and particularly in upright furnaces used for roasting quicksilver ores. Its object is to provide a furnace of this character which may be operated continuously, one wherein the ore may be acted on by the heat from all sides and wherein the heat is also made to pass through the contained ore and out again, carrying with it the mercurial vapors, and one wherein the ore will be dried as it enters the ore chamber, so it will not hang upon the tiling.

HAME ATTACHMENT.—No. 783,908. Feb. 28, 1905. T. E. Stockford, Leesville, Cal. This invention provides a convenient adjustment and in connection therewith a guard plate which protects the collars worn by horses, and prevents injury. It comprises a guard plate which extends across the belly of a horse collar and interchangeable from one horse member to another, said plate having its front edge hinged to one of said members and having a vertical series of slots in the opposite edge, a pin passing through the said series of slots to adjustably receive draft attachments, said pin having a transverse slot, and springs at opposite sides of the center of the plate in the path of the pin, whereby said pin may be inserted from the top and locked, whichever edge of the plate may be upward.

THE proposed changes in stamp mill practice in the Lake Superior copper region are of some importance to the copper industry and particularly to that district. It is intended to compound the stamp heads, by means of which a double head, it is estimated, will increase the output about 50%, at small increase in cost of power and other expense of operation. This will materially cheapen the cost of producing copper on the Lake, and will doubtless increase the output also. The proposed change has passed the experimental stage, as the idea has been given extended trial at the Osceola and other mills, and pronounced a success. The increase in stamping capacity will either result in running of fewer heads at less expense than at present, with about the same output, or with increased output means elaborate changes and additions to concentrating and other machinery in existing mills.

WHEN hydraulic mining was at its height in California, and was carried on without restriction, the cost of washing the gravel per cubic yard was reduced to a figure so low that this class of mining came to be acknowledged as the least expensive in the world, for the amount of material moved. There was considerable variation in this expense at the various mines, it is true, dependent on the thickness of the gravel deposit, the available grade; and amount and pressure of water obtainable, as well as the character of the gravel itself, but most of the larger mines operated at a cost ranging from about 3.7 cents to 7 or 8 cents per cubic yard. At that time no one thought that in a few years dredging for gold would become a great industry, or if anticipated, that the cost of mining by this method would compare favorably with the cost of hydraulicking on a large scale, but such is to-day the fact, for dredging in California has been reduced, in the Oroville

region, to a figure corresponding closely with that of operating the great hydraulic plants of the '70's. A well equipped dredge of large capacity, and gravel which does not offer too many difficulties to its handling, can wash gravel at a cost of about 5.5 cents per cubic yard.

## Smelter Fumes Again.

The United States Circuit Court has issued an injunction restraining the Mountain Copper Company from further damaging the forests in the vicinity of Keswick, Shasta county, Cal. This suit has been dragging along for several years with the result that the Government has finally secured a victory, but it is a victory of questionable value. The forest about Keswick consists chiefly of scattering nut pine, brush and a few oaks. That the smelter fumes have injured this sparse and stunted growth of trees there is no doubt, and, also, the contention of the Mountain Copper Company that the damage was relatively slight is, without doubt, true, but evidently a principle must be upheld, and, as a result, the town of Keswick, with all of its prosperity and diversity of commercial interests, is doomed. The Mountain Copper Company has given employment to more than 1000 men at its smelters, and a single monthly wage paid to these men would pay for all the timber situated within the zone in any manner affected by the smelter fumes. The plant at Keswick is a large one and contains a complete and extensive equipment. There are five water-jacket furnaces, having a combined daily capacity of nearly 2000 tons. There are eleven calcining furnaces, three converters, and a large amount of other machinery. Thousands of tons of ore have been heap-roasted in the past, and the fumes from these heaps, as well as from the stacks, has afforded numerous opportunities for complaint on the part of small farmers who will now find that they have lost the only market for their products which they have had for years. The works has also afforded a market for the gold-bearing siliceous ores of the district, but with the closing down of the works which will probably follow this recent court decision, Shasta county will have lost a most important factor in its commercial life. Among the harrassing experiences to which the company has been subjected was a strike of union miners, in 1903, which was continued for months, but in which the company was eventually victorious. Expensive fires have also occurred in the mines of the company, and it has had other misfortunes to contend with. In anticipation of the probable final outcome of the suits instituted against the company, extensive arrangements have been made to transfer a large part of the reduction of their ores from Keswick to a new plant in Contra Costa county, Cal., near the town of Martinez.

Within a few days it has been reported that money has been subscribed with which to carry on litigation against the Selby Lead & Smelting Co., whose works are at Vallejo Junction, in Contra Costa county, Cal. The principal complainants are said to be the residents of the vicinity of Benicia, in Solano county, on the opposite side of the Straits of Carquinez, and 6 miles distant in an easterly direction. The Selby Works have been in operation there for many years, and it would seem that the discovery has just been made that the fumes from the stacks are injurious. The only method as yet pointed out by which the various smelting companies of the West may hope to continue business is that they may engage in the making of sulphuric acid as a by-product of their smelting operations. This is entirely practicable, but it involves a large outlay of capital for plant, and considerable expense thereafter in carrying on the acid making. But after having made this great quantity of acid there will be no market for it which can be reached by the manufacturers where the product would bring a price which would even pay for the cost of manufacture. It has been suggested that the acid could be employed in the leaching of partially roasted ore, thus saving the expense of smelting. It is not a difficult matter for one with a knowledge of chemistry to work out scientific processes on paper, but the business of mining and smelting of copper ores is not conducted for the purpose of demonstrating scientific theories, nor even facts, but for profit, and when no profit results from the operation the proposition usually comes to a standstill sooner or later.

## Gold Mine Reserve Fund.

A liberal treasury cash balance, or an amount of gold bars on hand equal to about a month's output of the mine, is a desirable thing, but one which few mining companies carry, because of the demand for dividends on the part of the stockholders. There are few metal mines where the bullion output is absolutely regular from month to month, but by placing the amount at a fair month's average of a year's run, this amount may be readily ascertained—and if a surplus of amalgam or gold bars be kept on hand by the superintendent, under ordinary conditions, the monthly output can be regulated so as to approximate a stated sum. In some mines it is possible to do this by selecting the grade of ore to be treated, if there is considerable difference in the grades of the ore. Particularly is this the case with a low-grade mine having rich streaks. Should the output for the month be running behind the average, toward the latter part of the period, the superintendent, who is aware of this fact, directs the foremen to break a given number of tons of ore from known rich streaks, veins or deposits which have been held in reserve for such a contingency. By this means the average may be maintained, or a discrepancy may be adjusted, by adding amalgam from the reserve on hand.

Nothing gives such confidence in a mining stock as regular and continuous dividends, and nothing makes stock values so unstable as irregular dividends. Some believe that by holding a reserve the management is enabled to work low-grade ore which could not otherwise be worked, but this is not a fact. Any ore too low grade to work can not be made better or worked less expensively by drawing upon the treasury reserve or the amalgam safe. It is often the case, however, that the mining of rich streaks and bunches from a body of low-grade material, while the poorer rock is left undisturbed, results in closing a good property too early in its career. This system of mining, known as "gouging" or "gutting" a mine, is sometimes resorted to for the purpose of making a good showing for the manager, who, when he can proceed no further, resigns with a good record, leaving a gouged mine for his successor. The low-grade rock may not justify extraction alone from partly caved and badly timbered ground, but had the poor ore been broken with the rich in the first place, the difference in the cost of mining may have made the low-grade ore profitable. Occasionally the result of such operations as outlined above is to cave a large mass of low-grade ore which thereafter may be recovered at a very low cost, there being little mining, as mining is generally understood, to do, as the cost of drilling and blasting holes, timbering and other incidental expenses are practically eliminated, but such fortunate outcome of the former bad policy is of rare occurrence and limited extent.

## The Mexican Dynamite Monopoly.

Although the dynamite monopoly seems to have been firmly established in Mexico, there is a possibility that it may be declared unconstitutional, and the proposition is attracting considerable attention from the Mexican press. Article 28 of the constitution of the Republic of Mexico is as follows:

"There shall be no monopolies nor privileged places of any kind, nor prohibitions with titles of protection to industry. Those only shall be excepted which relate to the coining of money, to the postoffices, and the privileges which, for a limited time, the law may concede to inventors or perfectors of some improvement."

One of the leading Mexican dailies, the Record, says editorially: "If this concession stands, what will it not lead to?"

The company having the monopoly of the manufacture and sale of explosives in Mexico has already had a protective tariff placed on dynamite about equal to the first cost of 40% dynamite in the United States, which means that mining companies operating in Mexico must pay two prices for explosives. It will at least have one practical effect—that of teaching miners to break ground with the least possible amount of powder. In any event, it can not but have a harmful and restraining influence on the development of the mines of Mexico.

## CONCENTRATES.

A MILLIMETER is about  $\frac{1}{25}$  of an inch—or, more correctly, 0.03937 inch; 26 millimeters = 1.02362 inch, or, practically, 1 inch.

\*\*\*\*\*

THE metal tantalum is rare, and the metallurgical processes by which it is produced from its ores are complicated. A German firm sells the metal at \$9.50 per gram.

\*\*\*\*\*

MUCH better light is obtainable at shaft stations underground if the timbers and exposed rocks be white-washed or painted white. By this means a better light can be had at less cost.

\*\*\*\*\*

IN regions where water power is available for only a portion of the year it is not uncommon to find auxiliary steam plants to replace the water power during the dry months. This permits economy of power cost during at least a portion of the year when the wheels may be utilized.

\*\*\*\*\*

SOME convenient hydraulic formulas are: Pounds pressure per square inch = 0.434 times the head of water in feet. Head in feet = 2.3 times the pounds pressure per square inch. The weight of a cubic foot of water = 62.4 pounds. The weight of a gallon of water = 8.33 pounds. There are 7.48 gallons in 1 cubic foot.

\*\*\*\*\*

A FORMULA by which the friction in water pipes may be calculated is as follows:  $F = \frac{L}{1000 D} (4V^2 + 5V - 2)$ .

In this F = friction head; L = length of pipe in feet; D = diameter of pipe in inches; V = velocity in feet per second.

\*\*\*\*\*

WHAT is known as the Boss process is a method of amalgamating in pans by passing the pulp from one pan to the next in a series, practically making it a process of continuous amalgamation. The chemicals employed are the same as those used in the Washoe process and are principally sodium chloride (salt), copper sulphate (blue-stone) and quicksilver.

\*\*\*\*\*

THE principal elements occurring in and forming the rocks and ores of the earth's crust are, oxygen 47.3, silicon 27.2, aluminum 7.8, iron 5.4, calcium 3.8, magnesium 2.7, sodium 2.4, and potassium 2.4. The other elements occur in almost infinitesimal quantities relatively to the others above mentioned. Carbon is, perhaps, the next most abundant element in nature.

\*\*\*\*\*

THE new mineral, said to resemble garnet in crystallization and general appearance, reported from Vienna, is heckite. It is said to contain combinations of cerium, lanthanum, and other rare earth minerals, similar to monazite. If found in sufficient abundance, this mineral will become a valuable source of these minerals, which are used in the manufacture of light mantles.

\*\*\*\*\*

"THE Story of Amalgamated Copper" is not being told in the Eastern magazine mentioned, nor is it likely that it will be so related. That story is not one of New York, but of Montana, the facts only procurable where they transpired. It has been related as those facts transpired seriatim, and the alleged publication of the "story" (as as yet unfurnished performance) is ascribable to other motives than a desire to serve the public.

\*\*\*\*\*

WHERE the rock in a shaft is hard but fissured by soft seams which interfere with drilling, it is advisable not to attempt to drill deep holes, and better to use a "cross" hit which fetches less easily than with a chisel bit. Short holes—2½ to 3½ feet—can usually be put in any kind of ground, and the blasting accomplished without unnecessary delay, but deep holes if lost by fitching may make considerable difference in calculated results of the round of holes.

\*\*\*\*\*

COPPER ORES range from about 24% in some varieties of chalcopryite to over 80% in pure cuprite (red oxide), but these ores are so mixed mechanically with gangue and associated minerals that few of what are recognized as copper ores commercially average over 10%. The richer portions of copper ore deposits are usually at or near the surface, or at least above the sulphide zone. The Copper Queen mine of Bisbee, Ariz., averaged about 23% for several years in the early '80's.

\*\*\*\*\*

MANY mistakes are made in planning mills for amalgamation, cyaniding and concentrating. Often it seems as though the fact that there is such a thing as gravity is lost sight of entirely, and where gravity may have been taken advantage of are found various mechanical devices, all of which cost money to install and a constant expense to operate and repair. Where gravity can no longer be employed there are a number of excellent devices for handling materials, ore, etc., among them bucket elevators and push and belt conveyors.

\*\*\*\*\*

THE specific gravity of copper is 8.93, that of aluminum 2.68. The relative conductivity for equal area for the two metals is, for copper 100, aluminum 63. Their weight for equal conductivity is, for copper 100, aluminum 48.

Area for equal conductivity, copper 100, aluminum 160. Diameter for equal conductivity, copper 100, aluminum 126. The relative diameters of copper and aluminum wires, to be of equal conductivity, show aluminum to be about two sizes (Brown & Sharpe gauge) larger than copper.

\*\*\*\*\*

THE Grand Canyon of the Colorado river in Arizona has a variable depth, the north wall being somewhat higher than the south wall. The north wall at Bright Angel is about 6000 feet high. The south wall at the same place is about 4700 feet high. The difference is due largely to dip of the formation to the southward, and also to a possible fault. The width of the canyon is from 12 to 20 miles, measured from the upper platform. The Royal Gorge of the Arkansas river in Colorado is about 2000 feet deep. It is cut through granite and gneiss.

\*\*\*\*\*

UNDER a head of 2000 feet, a nozzle of 1 inch diameter will discharge 117.6 cubic feet of water per minute and will develop, if directed on a wheel of proper construction, 378.55 H. P. This calculation assumes that a pipe of proper diameter be used to carry the water to the nozzle, as in a pipe of diameter but little larger than that of the nozzle, the friction would be so great as to greatly reduce the power. A nozzle of 2 inches diameter, under the conditions above stated, will give four times as great a discharge and amount of power as one of 1 inch diameter. The power developed increases as the square of the diameter of the nozzle.

\*\*\*\*\*

THE amount of water required in coarse concentration of mineral, as at some of the Butte, Mont., copper mines, is variable, but ranges from 4000 to 8000 gallons per ton of ore treated. It depends largely upon the character of the ore; those having much clay in the gangue require more water than those where the gangue is clean quartz. In many cases, where there is a scarcity of water, it may be settled in large tanks or ponds and pumped back for re-use with a loss of 20% to 40%, due partly to evaporation and partly to mechanical loss. In figuring on the water consumed in steam making it is customary to allow about 1 cubic foot per hour per horse power. Some plants consume more than this amount, and others considerably less.

\*\*\*\*\*

TIN ORE (cassiterite) was discovered in the Etta mine, near Keystone, in Pennington county, S. D., in 1880. The mine at the time was being worked for mica. The heavy, black minerals attracted attention and samples were sent to competent chemists for determination. The analysis showed the presence of cassiterite, wolframite, columbite and titanite iron ore—all heavy, submetallic, black or dark brown minerals. Besides these, there was abundance of black tourmaline, from small needles to three-sided crystals a foot in diameter; black mica (biotite); muscovite (colorless mica), for which the mine was being worked; white, bluish and beautiful rose quartz; several varieties of feldspar; a small amount of emerald nickel; nickel sulphide; apatite in good-sized crystals, an inch or more in diameter and a foot or more in length, interpenetrating other crystals of feldspar, etc., and crystals of spodumene, mostly of gigantic size, the largest over 50 feet in length and 4 or 5 feet in diameter—a mammoth hexagon. The greater part of the tin-stone occurred in greisen, a rock largely composed of quartz and scales of honey-yellow mica. The mine was aptly described by a geologist and mining engineer, who once visited it, as a kaleidoscope. Tin was discovered at Nigger Hill, in western Lawrence county, S. D., at about the same time in the gold placers.

\*\*\*\*\*

THE value of a free gold prospect cannot be judged by counting the "colors" that a pan may be found to contain on washing, without an approximate idea of the value of the colors, and this can only be learned by experience from practical application of some method. If in prospecting gravel in the pan an average of ten colors of nearly uniform size is obtained in each pan and the gravel actually produces \$1 per yard, then the prospector soon learns that ten colors in the pan means \$1 dirt, and he can estimate the value at more or less as the number of colors increase or decrease in the test panning. This is a rude and haphazard method at best and cannot be relied upon to give accurate results. A better way is to carefully weigh each pan taken as a sample, and then weigh the result in gold, when by simple proportion the value per yard is readily estimated. If there is much large rock, boulders, etc., this method is also only an approximation. In prospecting quartz the prospector can much more readily arrive at a reasonable approximation of the value of the ore by practice and by a knowledge of what the rock he samples from day to day actually mills. For years the Homestake Co. at Lead, S. D., employed a sampler whose duty it was to dry, weigh out, crush and pan two-pound samples of ore delivered to him by the mine foreman. A regular system was followed, which made it possible to keep a very close check on the output in free gold monthly. Every sample was marked with the locality from which it came, and after testing the value in free gold, as estimated by the sampler, was written in a book kept for the purpose. The superintendent, by consulting the book, could tell within a few thousand dollars of what the output would be at the end of the month, and directed mining to be done on poorer or higher grade rock as was required to make an even output. About sixty two-pound samples were treated daily. The samples were placed in individual steel pans, dried on a flat

topped furnace, crushed to about one-fourth mesh in a large mortar provided with a pestle and spring pole. From this mortar it was dumped (swinging on trunnions) into a pan, dumped into a second large mortar, above which was arranged an old machine drill provided with a pestle with a large head. This quickly pulverized the sample sufficiently fine to pan without further grinding, when the sampler would carefully but quickly concentrate the gold by washing it in an ordinary steel miner's pan. The outfit was ingeniously and conveniently arranged, and where a large amount of sampling is to be done at a mine it will be found that a machine drill which may have outlived its usefulness in the mine may be sufficiently good for crushing samples for panning, or preliminary to assay. It saves much time and the process is inexpensive.

\*\*\*\*\*

A MINING CLAIM once located, the title vests in the locator or locators, unless by failure to comply with the law, the claim becomes subject to relocation, and is taken by some one else. So long as no second claimant appears to appropriate that which the former locator leaves open to location through his negligence, the title rests in the original locator, but having failed to comply with the law, and another relocates the claim, the original locator loses his right and title in the property. Where A and B together locate a claim and jointly perform the required annual work for several years and then fail for two years or more to do any work, A can not relocate the claim for himself alone as against his co-owner, B. Where several names are placed on a location notice, all of those whose names appear become vested with a legal title to the claim, and the estate so acquired cannot be divested by making a second location leaving out the names of some of the original locators, so long as the first location remains valid and subsisting. If some of those whose names at first appear on the location notice have abandoned or forfeited their rights by failure to live up to the terms of the original agreement under which the claim was located, a relocation may be made by the original co-locator or agent in his own name, but where the location becomes subject to relocation by reason of failure to perform the necessary annual work required by law, the matter is different, for one of several co-locators can not locate the claim for himself alone, and if he does so and performs the necessary work, his only recourse would be to advertise his partner out as provided by law, and to do this it is not necessary to make a relocation. If the partner offers to pay and does pay his share of the assessment work performed, he may retain his interest in the location.

\*\*\*\*\*

ALL of the placer gold found in California, as well as elsewhere, was derived originally from quartz veins and other gold-bearing ore deposits in place, but in many instances this gold has been subjected to erosive influences which has resulted in its being re-deposited several times. In the eastern counties of the central portion of California in what is generally recognized as the gold belt, the veins and gold-bearing lodes were first eroded by what are now known as the ancient rivers. In many cases, these ancient rivers have been cut by later, but still ancient, streams, and the gold deposited in the first streams has been freed from that portion of the first stream intersected by the second, and reconcentrated in the latter. In some cases this has occurred a third, and even fourth, time. All of the ancient streams flowed into the great depression (at that time a lake) between the Sierra Nevada and Coast range of mountains. The oldest of the ancient rivers deposited its detritus upon the bedrock (and near it), not only in the stream bed, but also of the great lake. Volcanic eruptions along the crest of the Sierra Nevada, which were contemporaneous with the ancient-river period, resulted in sending vast quantities of volcanic mud and rocks down the ancient streams, covering the previously formed gold-bearing beds of gravel in the beds of the streams. This volcanic detritus was also carried out into the great lake and spread out over the gravel deposits formed in the estuaries formed by the mouths of the rivers where they entered the lake. This process of forming gold-bearing gravel deposits which in time were covered by volcanic mud, sand, ashes and cobbles was repeated a number of times; and although these various geological occurrences are all recognized as occurring during one period of time (the Pliocene), yet they continued through many thousands of years, as demonstrated by the deep erosion of canyons through the previously formed lava-capped gravel beds. In the Mokelumne Hill region in Calaveras county, which may be considered as an epitome of the entire succession of the gravel channel-forming period, the difference in elevation between the latest and oldest gravel channels is not less than 500 feet, while the canyon of the Mokelumne river has been cut down 500 feet lower than the lowest ancient channel. In time the erosion of the mountain on all sides of the great basin or lake filled it and the lake disappeared, the surface of the detritus forming the lands of the San Joaquin and Sacramento valleys. During this ancient river period the Sierra Nevada was slowly rising, and it continues to rise as does the entire Pacific coast of California. This has lifted the valley a few feet above the level of the former lake and has given rise to the minor hills and river terraces which line the streams of the valley. With all the detritus coming down from the mountain streams, both ancient and modern, came a quantity of fine gold, and it is this that now constitutes the value of the dredging claims of the valley.

## Story of the Independence Alleged Salt-ing Case.

Written for the MINING AND SCIENTIFIC PRESS by  
GEO. J. BANCROFT.

Early in January, 1899, I went to Victor, Colo., to take charge of the sampling of what was then known as the Independence mine, belonging solely to W. S. Stratton of Colorado Springs. T. A. Rickard was making the examination on behalf of the Venture Corporation of London, and I took my orders solely from him. This was not the first time I had acted as Mr. Rickard's assistant—in fact, I had sampled at least thirty-five mines with him, or under his direction. Mr. Rickard explained to me that Mr. Stratton had not given an option on the mine, but that V. Z. Reed of Colorado Springs, Colo., had secured from Mr. Stratton a verbal agreement to sell the mine under certain conditions, which at that time were kept secret, and that the examination of the mine was a mutual one, to be conducted jointly by Mr. Stratton's agents and the Venture agents, to determine the condition of the mine and the extent of the ore reserves as a basis for concluding the negotiations. This explanation was brought about by my objecting to taking employees of the mine as helpers in cutting the samples. Mr. Rickard further ex-

plained that the examination was a mutual one, and looked upon the examination as a tiresome performance. This attitude on the part of the officers of the mine did not, however, interfere in any way with the sampling. Mr. Rickard was called to Colorado Springs the night before we began sampling, and, as I saw that the responsibility of the work would unavoidably rest somewhat heavily on my shoulders, I took all possible precautions against any tampering with the samples, not because of any fear that they would be tampered with, but because Mr. Rickard wished me to be able to say when the job was done that no one could have tampered with them, even if they had wanted to. It was a large job and I had felt the size of it keenly, and did not propose to have any flaws in my part of the work. So, in spite of its being a mutual examination, Mr. Rickard arranged for me to have absolute charge of the samples from the time they were cut till they were finally reduced to pulp and divided, one half going to Mr. Stratton's assayer and the other half remaining in my charge till it was delivered to the Wells-Fargo Express Co. for transportation to the assay office of Forbes Rickard at Central City, Colo.

We started in at the first level and sampled only those workings that were known to be in ore. No assay plan of the mine had been kept, and, as a Cripple Creek ore shoot is a difficult thing to locate by sight, we sampled beyond the supposed extent of

surface with Eicholtz or myself and unloaded. The samples were placed in the sampling room. This room had two windows and a door. The door was kept locked with a special Yale lock, of which Eicholtz and myself each had a key. We saw it was kept locked all the time except when Currie or Best were busy reducing samples. The windows were left unlocked, but were carefully sealed by putting several little pieces of string from sash to casement with sealing wax on each end. If any one had wanted to get at our samples, it would have been the most natural thing in the world for him to have opened a window and entered. These sealings were carefully inspected at the end of the examination and found intact.

While sampling was going on underground, Currie and Best were at work reducing them in the sampling room. This room was equipped with a crusher, "coffee mill" and dryer. The samples were dried and crushed to about 3-mesh in the crusher. The larger ones were then parted on a split-shovel once and then the coffee mill was used, reducing them to about 16-mesh. Each one was then mixed on an oil-cloth and reduced on a split-shovel to about a pound weight, when it was mixed and divided on an oilcloth, one-half going into one of the mine envelopes and one-half going into a paper envelope for shipment. These envelopes were packed in candle boxes, and as soon as one was full the cover was nailed on and the box

Taking Sample in the Back of Drift, Stratton's Independence Mine, Cripple Creek, Colo.

Taking Sample in the Face of Drift, Stratton's Independence Mine, Cripple Creek, Colo.

plained that every precaution must be taken to avoid arousing any suspicion that the mine was not being given an absolutely fair test, because Mr. Stratton was only half inclined to sell, and any little friction might upset the deal. Hence it was arranged that one of the officers of the mine should accompany the sampling gang at all times. As assistants I had L. H. Eicholtz Jr., who is now department superintendent at the Western Packing Co.; Walter Best, who was vice-president and general manager of the Northern Coal Co. at the time of his recent death, and Mr. Currie, who is now in South Africa. Mr. Stratton was represented by either James Emerson, the superintendent of the mine, or John Stark, the foreman. Frequently, however, neither of these gentlemen would be with us, because the officers of the mine had no faith whatever that Mr. Stratton would ever sell the mine, and regarded the examination as a useless interruption to the regular work, and additional trouble for themselves, with nothing to justify it. In fact, Mr. Stratton had never wished to sell the mine. As he put it, "The Independence mine is the only thing in my life that has ever stayed by me, and I propose to keep it." Mr. Stratton's plans, however, did not figure on the persuasive tongue of V. Z. Reed. So great was Mr. Reed's power of eloquence and argument that, after it was all over, Mr. Stratton maintained that Reed had hypnotized him and freely offered to trade back, although no one knew better than he that, so far as money went, he had much the best end of it.

It is no wonder, then, that the officers of the mine

the shoots; to be sure we got all the ore, but we did not try to sample the entire lengths of the drifts. Nearly all the samples were taken on the drifts, for the reason that the mine had carried itself and paid for Stratton's many benefactions out of the ore taken from development work, and only when an unusually heavy demand was made on the mine, as when new ground was bought or a lawsuit settled, was stopping resorted to.

The exposure of an ore shoot would be laid out in 10-foot lengths marked with chalk. Then the samplers would start in. Eicholtz and myself watched and assisted in the sampling. Both canvas sheets and boxes were used in sampling. All the samples were cut with hammer and moil. There were four or five men cutting samples. Generally they worked in pairs with a box; but when the vein was narrow and the drift low a sheet was used by each man. Very large samples were taken, the average being about thirty pounds per sample. This was ascertained by keeping count of the number of full cars of "overplus" that was trammed away from the sampling room. As each man or pair of men finished a sample, a clean canvas sack was furnished by myself, and, after sacking, it was given to Eicholtz, who tagged and sealed it. It was then put in an ore car which was pushed along as we went. It was my especial duty to see that each sample was taken fairly and in the right place, and it was Eicholtz's duty to see that each sample was properly booked, tagged and sealed; we both assisted each other, however, in our work. When the car got full it was sent to the

was tied with wire and the wire sealed. It was then taken to Wells-Fargo Express office and shipped to Forbes Rickard.

The final crushing ought to have been finer, as is shown by the variation between the two assayer's returns, but there was only one coffee mill and it could only grind so much per day, and everybody was "pounding us on the back" to get through. Mr. Stratton was very impatient of the delay. He did not altogether approve of "expert" methods and thought we were taking an unnecessarily long time to sample the mine. The sampling underground ran very much ahead of the reducing process, so that toward the last we had several tons of samples stacked up in one end of the sampling room. After Eicholtz and I got through underground each day, we platted the location and width of each sample on the maps of the mine. When we had finished underground we started a night shift on the reducing work and kept at it until it was done.

Walter Best and I then went down and took twenty-five check samples, two or three on each level, at places which we had previously sampled with the men. These samples never left us and there was absolutely no chance that they could have been tampered with. We took them with us to Denver and they were assayed by a Denver assayer. They checked nicely with the samples from the same places taken by the men. From the results of this sampling Mr. Rickard figured there were ore reserves of a gross value of \$6,700,000.

In November and December of last year (1904) I

was commissioned by the executors of Mr. Stratton's estate to conduct a second examination of the Independence mine, which had been ordered by the court, to ascertain if there was anything about the workings of the mine that would have a bearing on the allegations of the plaintiffs in the lawsuit known as Stratton's Independence, Ltd., vs. Tyson S. Dines, et al. Chas. J. Moore, of Denver, Colo., and W. H. Wiley, of Idaho Springs, Colo., were my associates. We found that the mine had produced about \$10,500,000 between that date and time of sale, and that most of the values had come from the ground sampled by Mr. Rickard; that of the 1008 places sampled by him only thirty-five remained unstopped. The balance has all been mined away, in spite of the fact that at least 300 of them were so low grade that Mr. Rickard considered them outside the ore shoots, and had not used them in his calculations. If any considerable part of the values of these samples were "salt," there must have been a lot of mighty low-grade ore mined. The thirty-five places found intact were resampled and the results check nicely with Mr. Rickard's results.

There follows a brief resume of the legal proceedings to date.

It will be remembered that the action was brought by the Venture Co. against the executors of the Stratton estate, and the complainant alleges in brief that Stratton represented the mine to have \$7,000,000 in sight, and to be reasonably worth \$10,000,000, when, in fact, the mine had only \$2,000,000 in sight and was worth only \$4,000,000. The fraud charge is as follows:

Stratton had caused the same to be examined and an estimate made of its value and of the amount disclosed in said property at that time and in making such examinations of the properties the same had not been honestly and fairly done, so as to show the actual value of ore disclosed therein; but the agents and representatives of Stratton, in making the examination, for the purpose of deceiving and defrauding the plaintiff, caused the samples taken from the mine to be salted, so that the estimate of the ore contained in the mine was fraudulently enlarged and the report based thereon was fraudulent and misleading, and that this fraudulent and misleading report was presented to the promoters and organizers of plaintiff company prior to organization and to its officers, agents and directors after organization.

That by reason of the matters set forth in the complaint, the plaintiff had been damaged in the sum of \$6,000,000, for which it asks judgment.

To this defendants made reply by six defences:

First. A general denial.

Second. That Stratton received nothing for the mine but stock. That while in form the transaction resulted in the conveyance by Stratton to the plaintiff corporation of all the mining premises described in the complaint, nevertheless, in truth and in fact, the same constituted but a change in the manner whereby Stratton held ownership and possession of the property.

As to this defence, Judge Riner says in part: "This being an action brought by a corporation, the facts set out in the second defence to my mind constitute a complete defence to this action. \* \* \* Whether what was done was done for the purpose of enabling the company to be passed off as something different from what it was is to my mind wholly immaterial to the present question. The remedy, if any exists, is a remedy of each purchaser of shares, if there were any such, who was deceived by the representations made by his vendor as to the conditions of the company."

Third defence. Denies that the representations set out in the complaint were made by Stratton or any of his agents, and alleges that full and ample opportunity was given to the plaintiff company to examine the mine and inspect the books.

Judge Riner says of this defence in part: "A defence which shows that the purchaser not only did not rely upon the false representations charged against the vendor, but availed himself of the opportunity afforded him to make the fullest examination, and did make such examination, and as a result thereof purchased the property, if supported by proof, raises an effectual bar to the plaintiff's case and is a good defence."

THE VALUE OF THE MINE.—As to the fourth defence, the following is Judge Riner's opinion in full, which covers the ground: "In the fourth defence it is alleged that, even though Stratton made the representations charged in the complaint, there can be no recovery in the case, for the reason that prior to August 1, 1903, the plaintiff had extracted and sold ores from these mining properties of the value of more than \$10,100,000, and, therefore, it has sustained no damage. The plaintiff alleges that Stratton and his agents represented that the mining property had exposed and in sight ore bodies of the value of \$7,000,000, and that the mine was reasonably worth \$10,000,000, whereas, in truth and in fact, the property had exposed and in sight ore bodies of the value of not more than \$2,000,000, and was worth not more than \$4,000,000. I am inclined to concur in the views expressed by counsel for defendants in their brief, that the statement made by Stratton, if it was made, to the effect that the property was worth \$10,000,000, constitutes in law nothing more than the mere expression of opinion, and is not actionable. This, I think, is true from the very na-

ture of the case. Whether or not the statement that there was \$7,000,000 worth of ore in sight was also an expression of opinion or a statement of fact it is not necessary for the court here to decide. Under the allegations of this defence of the answer, I think we may treat it as a statement of fact, and yet the allegations of the answer would constitute a defence, for, as suggested when we were considering the third defence, two things must concur: First, fraudulent or false representations in relation to the condition of the property; and, second, such representations must have constituted the basis of the sale on the part of the purchaser by which he was, in fact, misled to his damage."

The fifth paragraph of the defence alleges that at the time of the commencement of this action the defendants were not, and never have been, executors of the Stratton will; that the will had not been admitted to probate; that letters testamentary had not been issued to the defendants; therefore, that the action was prematurely brought. Judge Riner says in part: "I am led to the conclusion that suit against these defendants could not be maintained prior to their qualification as executors."

It is set forth that Stratton died before this action was brought, and it is insisted that the action does not survive him, and is not good against the executors of the estate.

Judge Riner says in part: "These occurrences must have taken place, if at all, in England, for at that time the company owned no property in this country, and, so far as the pleadings show, had no agent here, nor were any of the officers or directors residing here. This being true, I am inclined to think that the question of the survival of this action must be determined by the laws of England, and that, under the laws of England, the action does not survive."

Judgment was entered for the defendants.

## The Diamond Hitch.

Written for the MINING AND SCIENTIFIC PRESS.

The great interest taken in prospecting the past year and its increasing tendency throughout the West at this time with the coming of summer brings to mind the needs of the prospector who goes into the hills with pack horse or burro. To the uninitiated the packing of an animal for a trip of this kind seems a simple matter, but the writer, speaking from experience, knows that to place a pack on a horse, mule, or even on the humble burro, is no easy task—to secure it so that it will not plunge forward upon the animal's neck or over his head in case of a sharp descent, or ride on his hump in case of a stiff climb, or perhaps still worse, slip around under his belly, when a kicking performance usually follows which scatters the various articles of the pack along the trail or sends them rolling down the mountain side. There is no doubt that the best way to pack an animal in the presence of critics who are profuse with humorous but well-intended suggestions, is to allow them to do the job for you. It will pay to be considered a tenderfoot at the business for the lesson learned and the security afforded the pack, when placed by an experienced old-timer, but as this sort of aid is not always available the new hand should learn to pack for himself. The most famous of all the devices known to packers is the "diamond hitch." It is an ingenious but simple method of securing a pack on an animal. The requisites are a good pack saddle provided with back and breast and straps and a strong rope. Two men are required to pack by this method or any other method where articles are not tied to the various projections of the saddle or carried in bags. In throwing the diamond hitch one of the men is known as the thrower, the other as the cincher, the latter standing on the right side of the animal, the thrower on the near or left side. After the pack saddle has been firmly adjusted and cinched tight the pack is temporarily adjusted and secured to the pack saddle. The thrower then tosses one end of a broad band (similar to a cinch, and provided with a ring at one end and a hook at the other) under the animal's belly, and the cincher catches it by the hook with his left hand. The thrower then tosses the end of the rope backward over the left shoulder of the animal and across his right hip.

The short end of the rope having been securely tied in the ring, the thrower takes the short end, which is secured to the ring, in his left hand and the long end in his right hand and casts a short loop over the back of the animal. The cincher grasps the loop and catches it in the hook, pulling on the long end to draw it taut. At the same time he throws the remaining long end of the rope over the animal's back and toward its head to the thrower. The thrower then draws the rope around the top of the pack, passes it over and under the part of the rope first thrown, then forward around the forward left-hand side of the pack and backward along the lower side of it on the same side toward the rear, around the lower left corner and upward where the rope is passed beneath that first thrown. From there it passes around the upper right-hand corner, downward under the lower rearward right-hand corner

and along beneath the right side around the forward corner on that side, passing from thence upward around the upper forward right-hand corner where a second loop is made with the rope already in place, then downward on the left side beneath the lower left-hand forward corner of the pack and backward again to the rear, when the loose end must be securely fastened in the diamond formed by the rope at the top of the pack. The rope must be kept tight throughout the entire process and after passing the first loop must be tightly drawn.

The accompanying sketch will help to understand

The Diamond Hitch.

the manner of throwing the diamond hitch and its purpose. The only difference in the methods of different packers is that some start toward the rear end and some toward the forward end, but the result is the same. Considerable care and experience are required to get the pack secured by drawing the ropes as tight as possible. Pack animals soon become trained, and will deceive an inexperienced packer by holding their breath and swelling up until the pack is made fast, when they exhaust the excess air from their lungs and the entire pack is loosened.

## Topographic Maps of Colorado Quadrangles.

Maps of two interesting quadrangles, one of Ouray, Colo., and vicinity, and the other of the Needle mountains, in the same State, are now ready for distribution. Each represents a rectangular area approximately 14 miles east and west and 17 miles north and south in extent. The Ouray quadrangle lies directly north and the Needle mountains quadrangle directly south of the Silverton quadrangle.

The Ouray quadrangle lies partly in Hinsdale and partly in Gunnison counties and covers about 20 miles of the valley of the Uncompahgre river, all of Cow creek (Rio de las Vegas), and the headwaters of the middle and west forks of Cimarron creek. The mountains shown on the map include nearly all of the higher ranges between Mount Sneffels (14,150 feet) and Uncompahgre Peak (14,300 feet), among them Whitehouse mountain (13,496) and Wetterhorn Peak (14,020). Those rising along the eastern ridge of the quadrangle range from 12,000 feet to 14,000 feet above sea level and are unnamed.

The only important town or settlement in the quadrangle is Ouray, a city of 2500 inhabitants. Other postoffices in the quadrangle are Dallas and Ash. Ouray, which is widely known as a gold and silver mining camp, produces a daily output of gold alone approximating \$10,000 during a large part of the year. Among the mines tributary to this town is the Camp Bird mine.

East of Ouray lies a vast arena, 1½ mile in diameter and 1 mile in vertical depth, called "The Amphitheater," which is surrounded by volcanic walls that make it well-nigh inaccessible. Farther southwest Canyon creek enters Ouray through a box canyon so deep and narrow that it is said sunlight never enters there. Trails have been blasted in the quartzite walls and a portion of the canyon has been tunneled, so that the visitor may inspect the dark recesses.

The Needle mountains quadrangle is divided into two nearly equal parts by the San Juan and La Plata county boundary line. The Continental divide cuts across the northeast corner at the headwaters of the Rio Grande river. The largest stream shown on the map is the Rio de las Animas Perdidas, which flows for many miles through one of the deepest valleys in the United States. To it are tributary Vallecito and Needle creeks and Florida river. The Needle mountains and West Needle mountains, shown on this map, rise more than 14,000 feet above sea level and are among the roughest in the world and the

highest in the United States. Between them flows the Animas river, along which extends the Silverton branch of the Denver & Rio Grande Railroad. Needleton is the only postoffice in the quadrangle. There are no settlements, and the permanent population of the entire area is less than a dozen.

The head of Needle creek, in the Needle mountains, has recently been extensively prospected for gold and silver. The forest, extending down the slopes from timber line, which here lies at an altitude of about 12,000 feet, is of spruce, intermixed at 10,000 feet with quaking aspen, to which pine is added at 9000 feet, while cottonwood and other timber trees are found at lower levels.

The price of these maps is 5 cents each. They may be obtained on application to the Director of the United States Geological Survey, Washington, D. C.

### Artesian Water.

In many districts, particularly in some of the basins of the more arid portions of the West, there are possibilities for obtaining water by means of drilled wells. It is useless to hope for artesian water where the rocks are old, crystalline schists, granite or intrusive dike rocks, but in some regions where there are large accumulations of volcanic materials—tuffs, mud flows, etc., which occupy a basin or depression, there is sometimes the possibility of obtaining flowing water by boring. Unaltered sedimentary rocks—sandstones, shales, grits, etc.—offer the best opportunities for obtaining water by the comparatively inexpensive means, from great depth. The probability of obtaining water by boring should be looked into by a competent stratigraphical geologist before much money is expended in this direction, for many holes have been drilled through ignorance of the primary principles governing the obtaining of artesian water, where there was not the slightest hope of securing a flow. Pumping water may often be obtained in comparatively small amount by boring in crystalline rocks, but never a flow.

In a general way the geological conditions essential to the securing of artesian water are a stratum of comparatively open or porous rock, like sandstone, grit or conglomerate, in which there are abundant small open spaces which may be filled with water. This stratum must be overlaid by an impervious stratum like a close shale or bed of clay. The word impervious, as here used, is only a relative term, as no rock is absolutely impervious to water. What overlies the impervious stratum is immaterial. These strata should lie in a low monocline, or in a synclinal fold, the higher end or ends of the fold coming to the surface, in order that the rain waters may seep downward into the stratum. This stratum being penetrated by the borehole at a distance from the outcrop, the water, unable to rise through the overlying impervious layer, rises through the borehole. The accompanying illustrations show a variety of conditions under which wells bored for artesian water prove successful, or, for geological causes, fail of the purpose.

The following on the subject of artesian water, by I. C. Russell of the United States Geological Survey, is of interest to all who are interested in this important subject:

As the water supply in an artesian basin may become of importance to a large number of citizens, it is obvious that laws governing its use are as necessary as the laws relating to surface waters, but, so far as known, only one attempt to place legal restrictions on the utilization, or rather on the waste, of subsurface waters have been made in this country, and that act falls in two particulars to meet the requirements outlined above—the proper casing of wells is not made obligatory, and the filling of abandoned wells is not provided for. Each of these regulations is highly important.

The principal restrictions and conditions which it is desirable should be established and enforced by law are as follows:

1. Every drill hole in an artesian basin should be properly cased. By this is meant that an iron casing or tube lining the hole and made sufficiently tight to prevent water from rising outside of it should be put in every well which remains open. The lower end of casing should be just above the water bearing stratum.

The reason why the owner of a well should be required by law to properly case it, as already explained in reference to the personal interest of the owner himself, is that lateral escape of the water may be prevented. The escape of water from an artesian basin in excess of the natural overflow means a decrease in pressure on the portions remaining, and consequently a lowering of the artesian head. In arid regions especially the sources of supply of an artesian basin may be small, and the question of economically using the water it contains and of maintaining the artesian head are matters of public concern.

2. Every artesian well when not in use should be securely closed. The reason why a law to this effect should be enacted and enforced is that an artesian basin is not an inexhaustible reservoir, and every practicable means should be employed for its conservation and legitimate use. The closing of an artesian well when its water is not being used would in many and perhaps most instances be an advantage to its owner as well as to his neighbors, not only for the reason that his water supply would be made more permanent, but because

water flowing over land in excess of the amount required for scientific irrigation is injurious.

There are exceptional cases in which it is not desirable that an artesian well should be closed at any time, as, for example, when a well is no more than a developed spring, or derives its water from what is known as an artesian slope,\* but as such wells will probably be few in number in the artesian basins, special legislation in reference to them is perhaps not desirable.

3. Every abandoned drill hole in an artesian basin should be completely filled with impervious material. A desirable way in which to do this is to fill the hole slowly with moist clay and ram it down with a heavy, blunt tool, or fill the hole with Portland cement concrete. Tightly fitting rods of dry wood driven into a drill hole until it is filled would serve the same purpose.

Abandoned wells should be filled in the manner suggested in order that leakage may be prevented. Wells in which water rises some distance toward the surface, but does not overflow, are frequently abandoned, the casing, if any was used, having first been drawn, and in such instances a continuous escape of water occurs into cracks, porous beds, etc., about the hole.

The three rules briefly stated above should be embodied in the laws of every State in which artesian basins occur and their observance should be rigorously enforced.

For the proper development of an artesian basin it is evident that there should be but one center of responsibility. A desirable method of securing this end would be to place the entire control of the artesian wells in each State in the hands of a State engineer, whose duty it should be to determine where wells may be drilled, the

possible, depending upon the results of erosion of the upturned strata.

Fig. 5 illustrates the possible effect of erosion. A and B will result in producing flowing wells wherever penetrated by the well bore, providing the stratum C between them is not fissured and porous.

Fig. 6 shows how a condition similar to that in Fig. 5 may be disturbed by the shattering of the rock in the stratum C, resulting in the water contained in B flowing downward through the fissures in C into A, and thus draining B. A well sunk to B would under such conditions fail to flow, and if the bore were continued to A no flow would result above the outlet of the stratum at A.

In addition to these simple conditions are many others which may have a direct effect on the amount of water obtainable. When wells are sunk in porous water-bearing strata the surface exposure of these strata may be many miles distant. Often the water-bearing stratum contains minerals in solution, which render it unfit for use. The remedy, if there be one, is to bore deeper, though this is not always satisfactory.

### Water Supply by Compressed Air.

The water supply of Los Angeles, California, has in the past been received by gravity, only a few higher parts of the city being supplied by pumping

depth to which they may be carried, and methods for caring for the water supply, closing abandoned drill holes, etc.

While, in the majority of cases, good results may reasonably be expected from the judicious development of the artesian basins, all the benefits that might be derived in that way will be rendered negative unless the suggestions given above in reference to the conservation of the water supply are strictly observed. I may perhaps add as a warning that the wanton destruction of the forests in this country and the now almost complete ruin of the public grazing lands throughout the arid regions leave but little hope that man's greed will be so far restricted in the case of artesian basins that ultimate failures will be avoided.

Fig. 1 shows an ideal section, illustrating the main requisite conditions of artesian wells. A is a porous stratum, B and C are impervious beds below and above A. F is the height of water level in the porous bed A. W—W' are flowing artesian wells, springing from the water-filled stratum A.

Fig. 2 illustrates the thinning out of a porous, water bearing stratum between impervious strata. W is a flowing well having its source in A. DW is a dry well, which is sunk deeper than W, but for the reason indicated there is no flow.

Fig. 3 illustrates a porous stratum A changing to a dense, impervious one at B. W is a flowing well and DW is a dry well, there being little or no water in the stratum at B.

Fig. 4 shows the usual manner in which strata reach the surface. A and B are porous beds; C and D are impervious beds, and E is a semi-porous bed between A and B. B at one end is lower than at the other, and also lower than A. Many variations are

into the mains. The growth of the city, however, has made an additional supply necessary and a pumping plant is to be installed in the southwestern part of the city near Slauson Junction, where wells have been bored to water bearing strata 60 to 200 feet below the surface, these wells to be operated by compressed air. The system adopted is the air lift, in which compressed air is forced through one pipe down to the bottom of the well, where it discharges under the mouth of another pipe reaching to the top of the well and emptying into the reservoir. The bubbles of air issuing from the first pipe enter the mouth of the second, but do not fill it completely, as a considerable amount of water is carried in between the bubbles. The weight of water within the second pipe is thus less than that in an equal cross section of the well exterior to the pipe. The pressure of the water in the well, therefore, is greater and forces the mixture of air and water in the pipe to rise constantly, and as the bubbles of air are continually supplied at the bottom, this process goes on without intermission, the mixture of air and water discharging at the top of the well in a practically constant stream. The air, as it rises toward the top, expands, thereby returning the work which was expended in its compression, and as in expansion the temperature of air is greatly reduced, it serves at the same time to cool the water.

The twelve wells will discharge into a common reservoir, from which the water will be forced by a pumping engine into the city water mains. The water in the wells at present stands about 60 feet below the surface, but, as has been found in irrigation work in California, the ground level of subter-

anean water supplies is apt to be lowered considerably by continuous pumping, and the compressor has therefore been designed to pump, if necessary, from a lower level, being guaranteed to deliver 2000 cubic feet of air per minute against a pressure of 100 pounds. The compressor will be installed by the Baker Iron Works, of Los Angeles, who are local agents of the Laidlaw-Dunn-Gordon Co.

The Los Angeles machine will be of the two-stage type, the air partly compressed in a large cylinder, after which it will pass through a cooler, where its temperature will be reduced by passing over tubes containing cold water, to a high pressure cylinder, where the compression will be completed. The steam engine driving the compressor and forming, in reality, a part of it, the steam cylinders working on the same piston rods, is also compounded, the steam expanding first in a high pressure cylinder, after which it passes to a receiver, where it is dried and reheated by high pressure steam in pipes, after which it finishes its expansion in the low pressure cylinder. The steam is then condensed in a surface condenser and returned to the boiler through reheaters by the boiler feed pumps.

### Stave Pipes for Conveying Water.\*

Written for the MINING AND SCIENTIFIC PRESS.

The use of wooden pipe for conduits and pressure mains has increased rapidly during the past few years, and the box flume and ditch are fast giving way to this more economical method of conveying water. Among the most notable examples of stave pipe installed during the past season is that of the Washington & Oregon Power Co. on the South Fork of the Walla Walla river, in northeastern Oregon, in connection with their hydro-electric power plant.

This conduit conveys the water from the headworks of the system to the receiving reservoir situated some 5½ miles distant.

The one feature of the work which gives the structure especial prominence in the list of difficult undertakings is the alignment and the topography of the country which made this alignment necessary. The whole region lying on the westerly slope of the Blue mountains is covered by an immense lava cap, and it is through this that the Walla Walla river has cut its channel, leaving the marks of its centuries of labor in the perpendicular cliffs which mark the boundaries of the canyon.

It was along the south wall of this gorge that the line was located. A uniform gradient of 17½ feet per mile was used, and as the average gradient of the stream is 80 feet per mile there was a net gain in elevation of 62½ feet per mile.

The receiving reservoir is situated on a smooth hillside at the mouth of the gorge, and from this reservoir the water is delivered to the Pelton water wheels under a head of 350 feet.

Curvature was limited to a minimum radius of 200 feet, but no limit to total angle was fixed. The original location showed 90% of the entire line on curves, and of this over 50% was sharper than 250 feet radius. The remaining 10% was located as tangent, but as it was largely in very short sections, from 5 feet to 10 feet, it almost entirely disappeared in the construction.

The foundations consisted of a combination of bench blasted out of the solid rock, bench and cripple bent trestles, and full trestles where the limit of curvature would not permit of the other forms. Where the full bench was used cross ties of 4x6 inches were placed and on these the pipe rested. The pipe was further supported by cradle blocks, consisting of 4x6-inch blocks, cut to fit the outside circle of the pipe. These were driven under the pipe on top of the cross ties on both bench and trestle until a perfect bearing was had, and then the block toe-nailed to the tie. This gave support to about one-fourth of the entire circumference of the pipe.

At five different points along the line deep narrow side canyons entered the main canyon. These were too deep to cross at grade. At these points inverted siphons were introduced into the line. In these the pressures varied from 20 feet to 170 feet, and the maximum curvature, both horizontal and vertical, was used.

The pipe was built by the National Wood Pipe Co. of Los Angeles and San Francisco, Cal., owners of the Wheeler patent, under which it was constructed. The staves for the pipe were cut from 2x6-inch yellow fir and kiln dried. They were provided with a horizontal slot in each end to receive the oak tongue used for butt joint connection. These tongues were made 3 inches in length measured with the grain, and were provided with a small bead about ⅛-inch in all dimensions along the center of each end grain. In width across the grain they slightly exceeded the width of stave at the slot, this excess being embedded in the adjacent stave by cinching.

The hands were round mild steel, having a tensile strength of from 58,000 to 68,000 pounds, ½-inch in diameter, except for pressures over 100 feet, where those having ⅝-inch diameter were used. Each end of the band was provided with a rolled thread 5 inches

long, a hexagon nut and No. 12 gauge steel washer.

The shoes or lugs for connecting the bands were malleable iron and of such design as to permit free access to each nut in cinching, and still give perfect support to the staves without flattening the pipe.

The material was delivered at Milton station on the O. R. & N. Co.'s railroad, and from there hauled by the power company's teams 10 miles to the site of the work.

The line being from 20 to 350 feet above the valley, and on an almost perpendicular bluff, the task of delivering material to the work was no easy matter. For this purpose double drum hoisting engines were employed, using a heavy steel cable for a trolley, and a carrier operated by hoist and back haul cable. An average of 400 feet (board measure) of lumber or 1000 pounds of metal were hoisted each load. When the material was deposited on the grade it was loaded on hand trucks and distributed along the line, an average trucking haul of 2000 feet being found economical.

The work of construction was attended with many difficulties, both in actual erection of the pipe and in providing for the safety of the workmen. A very large percentage of the line was on trestle foundation, which made the work of curving the pipe extremely difficult, as the character of the bluffs made it impossible to brace the trestles against the strains imposed by curving the pipe. It was often necessary to drive gads into the rock and anchor the trestle by means of a chain and "twister" until the pipe was in place and cinched. In curving the pipe away from the bluff ordinary screw jacks were employed, a saddle cut to fit the outside of the pipe being used to jack against, this preventing flattening. When necessary to curve the pipe toward the bluff, chain blocks of one ton capacity were used, making fast to the bluff by means of a gad driven into the rock and to the pipe by a chain sling. In this case it was necessary to put a strut inside the pipe to prevent crushing. The chain blocks were left in place until the section was driven and firmly cinched, after which it would remain in position, then the whole operation would be repeated.

These operations on trestles, themselves 60 to 70 feet high, and in places where a misstep meant a fall of from 100 to 250 feet, made the utmost caution on the part of the workmen necessary. In the whole life of the contract there was no accident of any kind to workmen. Work was begun July 14, 1904, and the line completed December 31, 1904, sufficiently to permit the turning in of the water. On December 16th, after allowing the pipe sufficient time to swell, the necessary repairs were made which required three men one and one-half day's time. On the completion of these repairs the final certificate of completion and acceptance was issued by the engineer of the power company.

The plant was designed by Samuel Storrer, consulting engineer of Los Angeles, Cal., and was in charge of F. S. Badger, resident engineer. J. L. Stannard, engineer of the National Wood Pipe Co., was in charge of the work for the contractor.

### Shot Firers in Mines.

The proposal to legislate on shot firers in the mines of Illinois has led to the following printed argument from the standpoint of the miners:

To the Members of the Forty-fourth General Assembly Favoring Law for Shot Firing where Coal is Blasted as per Provisions of Senate Bill No. 18.

According to the reports made by the several mine inspectors to the Bureau of Labor for the year 1904, there were 157 men killed and 507 received injuries more or less serious.

A classification of fatal accidents by causes shows that 50% are directly occasioned by the use of powder. Desiring to reduce to a minimum the number of accidents resulting from this cause, we favor the enactment of a law similar in its provisions to that of Senate Bill No. 18, providing for the employment by the coal companies of the State, and at their expense, practical men whose duties it would be to discharge shots in all mines where coal is blasted off the solid, or where more than two pounds of powder is used in any one shot.

In support of a law of this character the following brief arguments and facts are submitted:

It is not alone the excessive number of fatal accidents which have and are now occurring, but the possibility of a frightful catastrophe, which under certain conditions is liable to happen at any time, that urge us to advocate this precautionary measure. The force of exploding powder, united with the dust necessarily created, occurring from so-called "windy shots" is great enough to wreck a coal plant, destroying not only the stoppings and other contrivances for directing the air currents in the mine, but even extending to the main or escape-ment shafts and disabling the ventilating machinery on the surface. An explosion of this kind recently occurred not many miles from the State capital in which several men were killed. Fortunately it happened at a time when but few men were at work, otherwise the loss of human life would have been great indeed. The chief object of the proposed measure is to prohibit shooting during the time the

miners are employed, and it requires no argument to prove that under this plan only the lives of the shot firers would be exposed, and their number would not exceed six or eight in the most productive mines in the State. These men would be familiar with mining operations, including the use and power of explosives, and as they have the authority, under the proposed bill, to refuse to discharge any blast that in their judgment would be dangerous to be exploded, the means of safety would be largely under their own control. Another evident point in favor of this plan is that it would educate miners, many of whom are impractical and some illiterate, in the proper use of explosives and in the general work of preparing shots. Under this plan the miner who drilled a "dead hole," that is, a hole drilled on the solid, or otherwise located in such a manner that the powder had no chance to perform the work expected of it, would be punished in the most effective way by having no coal to load the following day. One of the main objections, probably, that the employers would make would be that requiring them to pay for the services of shot firers. Under the present practice, recognized by the district agreement made between the operators and miners, is that of general shooting at or near the end of the day's work. The time of beginning shooting is anywhere from fifteen to thirty minutes before the expiration of the eight hours' work.

### The Nickel Mines of Ontario, Canada.\*

Written by W. E. H. CARTER.

A great deal has been written on the nickel areas surrounding Sudbury, Ont. There have been latterly but two operators in the field, the Canadian Copper Co., subsidiary to the International Nickel Co., and the Mond Nickel Co. The operations of the former far exceed all others in the business, both in the mining and smelting departments, and are even now being enlarged, while Dr. Mond's works have closed down for the present, with a large stock of matte on hand.

The old Copper Cliff mine of the Canadian Copper Co., still the richest in copper of any in the district, has produced latterly about 1000 tons per month from the bottom levels, at between 1000 feet and 1100 feet in depth. The ore has there broken up into irregular hodies, making diamond drilling necessary at their location. Another substantial shoot of ore was recently found in this way and is now being mined. The ore averages about 12% combined metallic content—10% copper and 2% nickel.

No. 2 mine holds good as ever in the bottom levels, at about 400 feet depth, the ore averaging about 3% nickel and 2% copper. The now abandoned open pit, measuring 217 feet in depth, with an average diameter of about 120 feet and nearly vertical walls, far exceeds in size any other of these open workings at the present time. The mine is in shape to produce 400 tons of ore per day with its one shaft.

Mines Nos. 3, 4 and 5 and the Stobie are in shape to produce in large quantities when that particular class of ore in each becomes needed at the smelter.

The output of ore for a while back has come chiefly from the Creighton mine, the present rate of mining there giving over 800 tons per day. The main unbroken ore body contains, by estimate from diamond drill exploration, over 3,000,000 tons of ore of a 6.5% nickel-copper content—about 2 of nickel to 1 of copper. There are extensions to this ore body which will considerably increase the total quantity. This estimate accounts for the ore body to a depth of but 300 feet, this being the maximum vertical depth bored by the drill, at which the depth of the deposit was about 225 feet.

In order to economize in the roasting and smelting operations the entire surface works have been rearranged, not at once but gradually during the past two years, and now a new or third smelter plant is about completed to replace both the others and also the Ontario Smelting Works, near by, where the low-grade matte is at present partially refined. There will be only two blast furnaces, but they will have a combined capacity of at least 1100 tons of charge per day, and from them the molten matte will run direct to the bessemer converters in the same building and be raised to a content of about 80% nickel-copper. The accessory plant, the buildings and the new power generating station and the general arrangement are after the most approved ideas.

With the completion of the new works all ore will be roasted in the new yard. This covers a distance of a mile or so from end to end, with heaps piled two deep and close together. Instead of the old dimensions of 40 feet by 80 feet plan by 10 feet high, the size of the heap has been reduced to about 25 by 40 feet plan by 6 feet high, with the expectation that it will roast better and in about one-third the time—that is, in from one to one and a half months.

The Victoria nickel mine before closing down reached a depth of 500 feet, after which diamond drill holes were bored from the bottom and from two stopes on either side of the shaft, and the ore found to continue down to greater depths. Since the com-

\*See illustrations on front page.

\*Abstract Trans. Can. Min. Inst.

mencement of smelting at the company's plant near the mine over 5000 tons of bessemerized matte, containing about 80% combined nickel and copper, has been produced. But only a part of this has so far been refined into the pure metals at the company's refining works in Wales. The Mond Nickel Co. mined and raised ore from the North Star mine during the past two years, shipping the same to its furnaces at Victoria.

All other mining on the nickel range has latterly been curtailed to exploring for other ore bodies, the work no longer limited to the vicinity of the Sudbury area, but reaching out to the boundaries of the field.

### Shaft Bins at Lake View Consols, Kalgoorlie, West Australia.

Written for the MINING AND SCIENTIFIC PRESS by D. E. BIGELOW.

The shaft has three compartments, two of which are for the double winder and the third is for sinking and as ladder and pipe way. The shaft is now 1900 feet deep and sinking is still under way.

A year ago it was decided to substitute skips for cages, and, to accommodate the former, ore bins

the gates and chutes were set and the bin bottom lined with steel plates. The bin posts were set 3½ feet in the clear from the shaft sets, allowing plenty of room for the skip tender.

Next the raise was enlarged enough to give storage for about 100 tons of ore. The gates are 28 inches wide in the clear and provided with double racks, so that bulging from pressure of ore does not bind the gear. The chutes are ¼-inch steel plates riveted to angle iron corners.

A very important detail is the design of the tail chutes for carrying the ore directly into the skips. These are so arranged that their own weight holds them in position forward or back as placed. After being used for filling, as shown in the farther compartment in the drawing, the ascending skip knocks the chute back clear of the shaft, as in the near compartment.

Another feature is the auxiliary swiveling gate in the chute, used to control the stream of ore should the upper gate fail by any chance. The auxiliary gate is simply a ¼-inch plate, bent as shown and swung on bolts to the sides of the chutes. While the ore is passing, the gate is swung as an arch spanning the chute and may be dropped quickly to hold back the ore, if required, as in case the upper gate is

were cut under the plats, and loading stations and chutes put in one side of the shaft, 30 feet below the plats at four different levels, from which the greater part of the ore was to be drawn.

In putting in the bins no interference with regular work in the shaft was to be tolerated, which condition added materially to the cost of the work.

The mode of procedure was as follows: The ladder compartment was planked over on the set, shown in the drawing, and partitioned off from the others up to the level above. This prevented stuff falling into the shaft, and gave protection to workmen in this compartment. The lagging was then withdrawn on one side a height of two sets in this compartment and cutting for the station begun. The dirt was raised by hand windlass to the plat above and loaded into trucks to be hoisted to the surface.

The station was cut the whole width of the shaft without removing the lagging from the two winding compartments, to a height of 2½ sets, and back on the incline to suit the bottom of the bin. All the dirt possible was left against the lagging, as protection against firing. Drilling was all hand work until after the first cut in the raise. The raise was carried up from the back of the station to the plat, 4x6 feet in size, using machine drills. After breaking through,

fouled or partially closed by a large stone. This arrangement gives as much security against losing ore down the shaft as the more expensive charging bin arrangement, and requires much less room.

The cost complete—all labor and material and general expenses—was as follows:

Labor and salaries.....	£	s.	d.
Explosives.....	183	13	10
Timber.....	29	19	0
Candles.....	9	8	1
Steel.....	4	10	0

THE Michigan College of Mines will hold its second annual class-day exercises in Houghton and Hancock, Mich., on May 5. A feature of the event will be the public address by W. G. Mather of Cleveland, Ohio.

### Mining on Gribble Island, B. C.

Written for the MINING AND SCIENTIFIC PRESS by W. M. BREWER.

It is necessary to travel up the coast of British Columbia to fully appreciate the immensity of the province, the great length of coast line, and the enormous areas covered by the numerous islands which are situated not only in the Pacific ocean proper, at variable distances from the mainland, but also in the many sounds, bays and inlets which penetrate for miles into the interior.

GEOGRAPHY.—Gribble and Princess Royal islands, on which are located mineral claims that have been in course of development for the past four or five years, are situated near the mouth of the Kitimat river, and are separated from each other by a narrow channel known as McKay reach. From Princess Royal island several shipments of gold-bearing ore of unusually high grade have been made to the smelters on Vancouver island and at Tacoma since 1902. This property is being rapidly developed into a mine which promises profitable results for the operations. It is situated on the westerly side of the island, and until recently has been the only prospect on which development work has been carried on, but at present a party of prospectors from Bellingham, Wash., are opening a prospect on the opposite side of the island, close to the beach.

On Gribble island two companies organized in Bellingham, Wash., have been carrying on operations for the past few years on the west side of the island, and within about 1 mile of each other.

The property on which the most development work has been done consists of ten claims owned by the Canadian-American Mining Co. The other, consisting of several claims, is owned by the Gribble Island Mining Co.

GEOLOGY.—Owing to the snow which had fallen a few days previous to the arrival of the writer at Gribble island, examinations of the surface were made with difficulty. The underground workings, however, which have been opened permitted a fairly accurate survey of the geology on that side of the island.

The similarity of the geological formations on Gribble island when compared with that on Texada island, nearly 400 miles to the southeast, or at White Horse, in the Yukon Territory, is striking, especially with regard to the occurrence and character of the ore bodies, but the geology cannot be said to be exactly similar, for on Gribble island the granitoid rocks, especially in the vicinity of the ore bodies, have a decided gneissic structure, a feature entirely absent in the other two districts mentioned.

Another dissimilarity is in the fact that, so far as at present exposed, the ore bodies, instead of occurring at the contact of crystalline limestone and igneous rocks, as is the case both at White Horse and on Texada island, are found between a gneissic granitoid foot wall and a diorite hanging wall. But with regard to the hanging wall, this is merely a conjecture based on conditions of the outcrop, and not from underground exposures, because sufficient crosscutting has not been done in any place to determine either the character of the hanging wall or the width of the main ore body.

A well-defined diorite dike is noticeable on the beach at the landing place used by the Canadian-American Mining Co. The dike, according to reliable information, forms a prominent landmark through the island. Its average width is 12 feet and its line of strike north 20° east. On the easterly side no occurrence of minerals has yet been discovered.

The country rock on the westerly side of the diorite dike referred to has always been classed as granite, but a close examination with an ordinary lens caused the writer to form the opinion that this rock is composed of hornblende and orthoclase feldspar, and it should, therefore, be classed as syenite. A noticeable feature connected with it is observed in a tunnel 600 feet in length, which has been driven for the purpose of intersecting the ore body which outcrops on the surface. This feature is the change of structure and grain of the rock from a coarse grain near the mouth, with well-defined, large crystals, to a fine-grained rock near the ore bodies, with gneissic structure, evidently a syenite gneiss, because, so far as can be observed with the lens, it is composed of the same hornblende and feldspar, and apparently having no other minerals associated with these.

CHARACTERISTICS OF ORE BODY.—The ore body itself, so far as it has been exposed by open cuts on the outcrop—a tunnel and shaft—is a mass of considerable extent made up of crystals of variable size of bornite scattered through a matrix of garnetite and feldspar, the latter occurring in particularly large crystals of a pinkish color. Much of the garnetite is made up of large sized garnets almost perfect in their crystallization and of great beauty.

There is one peculiarity with regard to the foot wall of this ore body, which is that it resembles sandstone for about 1 foot in thickness, and in this can be seen grains of chalcopryite, but whether in sufficient quantity to give it commercial value is doubtful.

There is considerable epidote associated with the other minerals which make up the matrix.

Southerly from where the main outcrop has been

exposed by an open cut there occurs a steep bluff which has the appearance of being a continuation of the outcrop capping an ore body, but no work has been done to establish this fact.

**DEVELOPMENT.**—The development on this property consists of open cuts made on the outcrop, a short tunnel 40 feet below the outcrop, which was probably started with the intention of crosscutting the ore body, but was merely run until at the face about 3 feet of ore was exposed, when a shaft was started and sunk 37 feet in ore. At that depth the water interfered, and having no pump it was concluded by the management to drive a crosscut tunnel starting from a point 200 feet lower than the short tunnel referred to. At the time of the writer's visit this tunnel had been driven 600 feet, but had not yet intersected the ore body on which the shaft had been sunk.

At 425 feet from the mouth of this tunnel a lens of ore has been crosscut and drifted on for 30 feet. The ledge matter in this is made up of the same minerals as are found in the main ore body, that is to say, large crystals of feldspar, garnets and some epidote, with masses and crystals of bornite of variable size as impregnations, distributed variably through the matrix. If properly sorted, this ledge should carry good commercial value, but under present conditions with regard to freight rates the material would not pay to ship unless carefully sorted.

The line of strike of this ore body is almost parallel to that which outcrops higher up the mountain, nearly due north, but the dip is at an angle of 60° west, while that of the main ore body above is 65° east.

From a survey of the long crosscut tunnel it will be necessary to continue it for probably 100 feet, and also turn its course northerly in order that a raise may connect with the shaft referred to and the conditions of the ore body determined below the bottom of that shaft.

Judging from the extent of the outcrop, the fact that the shaft has been sunk 37 feet all in ore, and the continuity of the outcrop towards the north along the line of strike of the main ore body, it appears as though this property, if development is continued on the proper lines, should in the near future be placed in a position to ship ore. The tonnage, of course, would depend largely on the cost for transportation and the necessity for more or less sorting.

From the appearance of the dumps which have been accumulated, the writer is of the opinion that it will be found more profitable to consider the ore bodies as low-grade propositions rather than to attempt sorting.

**SHIPPING FACILITIES.**—There are few propositions located more advantageously for shipping than those on Gribble island. The mountain side from points where permanent workings would be located at both the Canadian-American Co.'s property, and also the Gribble Island Co.'s property to a deep-water harbor has a precipitous incline, raising about 800 feet in a distance of 2600 feet to the former company's property, while the proposition owned by the last mentioned company is at a lower elevation, and not as far distant from the shore line. At the present time connection between the landing at the beach and the property owned by the Canadian-American Co. is made by a well-constructed skid road  $\frac{1}{2}$  of a mile in length.

**TIMBER AND WATER SUPPLY.**—With regard to the supply of timber on Gribble island it is noticeable that the trees have a scrubby growth as compared with those further down the coast, but the supply is ample for mining and fuel purposes. Cedar, hemlock, spruce and some fir are the varieties on this as well as on adjacent islands.

A valuable water power can be developed from a stream which flows from a lake situated at 500 feet higher elevation than the outcroppings on the Canadian-American Co.'s property. Therefore any machinery required for mining plant can be run by water power instead of by steam.

### Jupiter Transmission Rope.

The Durable Wire Rope Co., 26-30 Atlantic Ave., Boston, Mass., sends a specimen of rope used for

transmission of power, which is composed of wire strands, each strand compactly served with tarred hemp marline, as illustrated, laid up around a spe-

cially prepared heart or center. The marline does not add to the strength of the rope, but is provided for the purpose of protecting the wire strands from wear by contact with outside objects, or with each other. After having worked over sheaves for some time, if treated with a mixture of raw linseed oil and graphite, the marline becomes packed, filling the interstices between the strands, and representing a smooth, cylindrical substance resembling hard rubber, thus protected from rust or moisture.

### Recent Improvements on the Rand.

Gold recovery in the Witwatersrand district, South Africa, is every day being more and more reduced to what practically means a manufacturing instead of a mining basis, says the London Mining Journal. In order, however, for such a policy to be carried out successfully, it is necessary that extremely careful records be kept of all the operations incidental to the process, and of these operations none is more important than the exact knowledge of the average grade of ore and the exact tonnage passed through the mill. This work is well exemplified in the new mill of the Village Deep Gold Mining Co., which has been started up. Here complete arrangements have been made for sampling and weighing all ore going through the mill. The ore enters the mill from the crusher house by means of a conveyor belt, which belt passes first over a weighing machine, which automatically records the total weight of ore entering the mill. The ore stream then passes over an automatic sampling machine, which deflects a definite proportion of the ore at regular intervals into a separate bin, which feeds but five stamps of the battery. This one mortar is, moreover, provided with an automatic pulp sampling machine, so that a fair average screen sample may be obtained, and this screen sample would represent the average grade of ore entering the mill in any given period.

The weighing machine is an ingenious piece of apparatus, and is now used at a number of mines on the Rand. The principle upon which the machine is constructed is that of weighing a given length of the conveyor at intervals of time corresponding to the travel of such length, and automatically recording the weight. Thus, if the machine is made to weigh 6 feet of conveyor, it will weigh and record every time 6 feet has passed, and so every portion of the conveyor will be weighed successively.

The chief features of the machine are:

1. A steelyard balanced to suit the unloaded conveyor, and arranged to rise accurately in proportion to the load.
2. A gripping device to hold the steelyard fast at suitable intervals.
3. A measuring gauge or quadrant to ascertain the weight indicated by the steelyard when so held.
4. A recording mechanism to exhibit the result.

The resistance of the steelyard to the load is provided by a hollow plunger suspended in a bath of mercury in such a way that it forms a dash pot or drag against undue oscillation.

The gripping and measuring actions are produced by two cams upon a shaft operated directly by toothed gears from the conveyor drum.

In the machine already made the cycle recurs every five seconds, and is as follows: The steelyard is free for about three seconds, during which time it assumes a position proportional to the load upon that portion of the conveyor which is supported by the weighing machine. It is then gripped by the action of the first cam; the second cam then immediately allows the measuring quadrant to move forward until it touches the steelyard, where it remains until pushed back by the same cam. The first cam then releases the steelyard. The weight is recorded by the backward stroke of the measuring gauge. There are thus four motions—gripping, measuring, recording, and releasing—which occupy somewhat less than half the time of the whole cycle.

It will be readily understood that when the steelyard is in its lowest or zero position it must touch the measuring gauge at its stationary position, as there can be no motion of the latter if the steelyard indicates no load. It has, however, proved impracticable to allow the steelyard to touch the gauge at the zero position, for two reasons: First, it is difficult to adjust the steelyard so finely that it touches the gauge and yet bears no weight upon it; second, the vibration of the conveyor gearing, etc., sets up oscillations in the steelyard, which would allow the gauge to gather a few pounds occasionally, and so introduce an error.

The difficulty has been overcome by balancing the steelyard at a position somewhat above zero, and then subtracting or discounting a corresponding amount of weight each time a weighing takes place. Thus, for instance, if the steelyard is balanced so as to remain in a position corresponding to  $\frac{1}{2}$  cwt. when there is no load in the conveyor, the measuring gauge will register on its return stroke  $\frac{1}{2}$  cwt. each time. If, now, a device is introduced to deduct  $\frac{1}{2}$  cwt. from the register each time, the motions cancel each other and the register remains unaltered.

The device referred to consists of a train of wheels, two of which gear with a pinion carried upon an arm of the wheel driving the register or counter.

It will be seen at once that if the two bevel wheels

move an equal amount, but in opposite directions, the result will be that the pinion is merely revolved upon its axis. But if one of the wheels moves more than the other, the pinion will be driven forward or backward accordingly, and will carry the registering wheel with it. To the spindle of one of these bevel wheels is attached a ratchet wheel having a suitable number of teeth (where the lever is balanced at  $\frac{1}{2}$  cwt. the number would be forty). A lever and pawl, operated from the cam shaft, drives the ratchet wheel one tooth for each cycle, deducting a corresponding amount from the register. The other bevel wheel is driven from the measuring gauge. The register or counter thus operated shows an indisputable record of the quantity passed over the conveyor during any given period—minutes, hours or days.

The measuring gauge, or quadrant, consists of a vulcanite plate securely fastened to a light steel frame. The frame encloses a finely divided steel ratchet wheel, and carries a set of ten pawls of different lengths, engaging the said wheel. This confines the error due to lost motion between the pawls and the wheel to one-tenth of a tooth. There is also a set of ten retaining pawls attached to a fixed stud on the body of the machine. The large steel ratchet wheel is keyed upon a spindle connected with the registering counter, and the frame carrying the pawls swings freely upon the boss of the wheel. This frame has a reciprocating motion imparted to it by means of the cam previously referred to.

These machines have been installed at the Village Deep, Van Ryn, New Goch, Roodepoort United and New Kleinfontein mines.

**SLIMES HANDLING.**—Perhaps one of the most notable tendencies in the newer slimes plants which are being erected on the Rand is the attention which is being paid towards reducing all power losses to a minimum. The first plant where this was fully carried out was that of the Robinson Gold Mining Co., where 10 inch centrifugal pumps, direct connected to motors, were substituted for the smaller sizes previously used, and, in connection with the use of these pumps, pipe lines were installed of sufficient size to bring pipe friction within reasonable limits, and the pumps themselves are run at their most economical speeds. The result of this change was that the 10-inch pumps required no more power to operate than the smaller pumps previously employed, although they did the work of running transfers in fifty-five minutes in place of six to seven hours required by the smaller pumps, so that the horse power hours required were considerably less for the larger pumps than the smaller ones. These pumps are provided with special manganese steel liners, manganese runners, and water service on the glands to prevent the slimes from entering the bearings, and they have shown records of eighteen months' continuous operation with absolutely no repairs whatever. Similar plants have been supplied to the Robinson, Village Deep, Witwatersrand and Simmer & Jack mines.

### A Useful Canal.

Two of the uses of the Chicago sanitary and ship canal, connecting the Chicago river at Chicago to Lockport, Ill., 23 miles away, are indicated by its name: It conveys the sewage of Chicago from the lakes down the Mississippi to the gulf of Mexico; it is almost as deep as the Suez canal, and, when supplemented by other waterways, will become an important commercial and military artery of travel.

At Lockport, the western end of the canal, it is to be put to its third great use—that of power. The water is to turn four water wheels driving electric generators; the electricity generated will be transmitted back to Chicago to light all the arc lamps of the city streets and parks.

Below Lockport much work had to be done so that the Desplaines river might accommodate the 600,000 cubic feet of water per minute that was to flow down it. For the whole project, including the part below the canal, 42,229,035 cubic yards of solid rock and earth were removed. Besides this there were 457,777 cubic yards of retaining wall and bridge masonry.

January 2, 1900, the great engineering work was completed and the waters of Lake Michigan allowed to fill the canal. This took thirteen days. January 17th the dam at the western end of the canal was lowered and the westward flow of water began. Thus the primary object of the canal, sanitation, is accomplished.

The canal is soon to realize its further utility as a source of power. Four water wheels will be used to drive four 4000 kilowatt, three-phase, sixty-cycle, alternating current generators, built by the Crocker-Wheeler Co., Ampere, N. J. The water wheels are of the Wellman-Seaver-Morgan horizontal type. A contract has been signed for the construction of these great dynamos, which will deliver current at 6600 volts. The Great Lakes are thus being utilized for power at both ends—at Niagara Falls and through this canal at Lockport.

The ultimate use of the canal as a section of a deep waterway connecting Lake Michigan and the Mississippi has been in mind ever since the inception of the project. The city of Chicago will have spent \$55,000,000 on this canal. If the canal had been built for sanitation alone, the cost would have been \$18,000,000 less.

### Shaft Bell Signals.

One of the most important matters about a mine operated through a shaft is the signaling arrangements. Electric signals have in late years been introduced into mines; but they do not appear to be in as great favor as the old-fashioned bell line, particularly in wet mines. Some mines have both systems, not having removed the rope-and-gong system when the electric device was installed, which is, generally speaking, a wise precaution on general principles.

The following is from a paper contributed by E. H. Garthwaite to the transactions of the Institution of Mining and Metallurgy of London:

The subject of mine signals, especially for use in shaft work, is of particular interest to the mine manager. Electric and compressed air installations have proved satisfactory for the purpose of signaling, and, where properly equipped and fitted, seem to leave little to be desired. In many mines, however, mechanical devices are still used, and in the majority of cases they do not prove remarkably efficient, as they are generally clumsy and require a considerable amount of brute strength to work them.

The writer would like to bring before the notice of the Institution a mechanical device which he came across many years ago in Mexico, and which he has since used with great satisfaction, especially in shafts 500 to 1000 feet deep; the device is equally well suited for vertical or incline shafts.

The accompanying diagram shows the arrangement of this device, and it will be seen that the bell rope from the shaft, whether vertical or inclined, winds around a drum made of wood with the sides bolted on; galvanized iron wire rope,  $\frac{1}{4}$  inch diameter, is generally used. An L-shaped lever is bolted to one side of the drum, to one end of which is attached a rope communicating with the engine room.

A special feature of the apparatus is the counterweight, which consists of an iron cylinder, generally a small oil drum, which can be filled with lead, scraps of iron, etc., so that it must counterbalance the weight of the bell rope. This makes it possible to pull the bell rope with a slight exertion, so that if

one is riding in a cage or bucket at a medium speed it is possible to give a signal to stop, if necessary. The counterweight rests on a bracket, and usually a guard is placed around it so as to prevent the possibility of its tipping over.

Gongs are distinctly preferable for the conveyance of shaft signals; but, unless it is possible to treat them gently, they generally get out of order very easily. With this device, however, a gong can be satisfactorily used, for overstraining is prevented by the lug A on the signal drum, which does not allow the drum to turn more than the distance between the lug and the upright iron frame. This distance is regulated by the length of pull necessary to ring the gong properly.

### Searchlight District, Nevada.

Searchlight, in the western part of Lincoln county, in southern Nevada, is taking a prominent place among the rich districts in that State. The Quartette, owned by Boston capitalists, and the oldest property in the district, has a 20-stamp mill at the Colorado river, connected with the mine by a railroad, and also twenty stamps at the mine. This property is now on a dividend-paying basis. Next to the Quartette lies the Good Hope, which is proving to be a duplicate of the former, while the Duplex Co. has a 10-stamp mill operating, and has opened up large ore bodies. The Cyrus Todd has made several shipments of high-grade ore and is preparing to erect a mill. The Santa Fe has been operating under a bond, having milling ore from the grass roots and at 120 feet struck water. The Southern Nevada, owned by New York capitalists, is operating a 10-stamp mill. The Blossom has some of the richest ore in the district. The Searchlight M. & M. Co.'s property, adjoining the Blossom mine, has three distinct separate ledges crossing it; on one a

shaft has been sunk 300 feet, demonstrating an 18-foot ledge, assaying over \$18 per ton. Drifts over 240 feet show the same ledge, carrying same values. The Pompeii, the most northerly located property in the district, has just developed a large ore body at 200-foot level.

### Calumet and Arizona.

The Calumet & Arizona Mining Company's property is at Bisbee, Ariz. Up to about 1900 the Copper Queen was the only large producing company in the Bisbee region, but the Calumet & Arizona Company, organized in 1901, came rapidly to the front and has since become one of the largest producers in the Territory. For more than twenty years the impression appeared to prevail that the Copper Queen Company owned and operated all the ground worth having in that locality, but the extensive development of the

Smelter of the Calumet and Arizona Mining Co., Douglas, Arizona.

Irish Mag and adjoining properties of the Calumet & Arizona Company has proven that mineralization is not confined to the ground owned by the former company. The reduction works of both the Copper Queen Company and the Calumet & Arizona are at Douglas, 26 miles from Bisbee, in Sulphur Spring Valley. The town of Bisbee is scattered along the irregular gulches and on the hillsides in the vicinity of the mines. Although the Copper Queen originally built and operated their smelters in the vicinity, the demands of the mine outgrew the facilities afforded by the Bisbee plant, which led to the construction of a new smelter at Douglas. The plant of the Calumet & Arizona Company is herewith illustrated. It stands on a good site comprising 600 acres. The ore is delivered at the works by the El Paso & Southwestern Railroad. The first furnace was blown in in November, 1902, the second one the following spring, and a third stack in October, 1903, and the fourth one later. The capacity is stated to be 1000 tons of raw ore daily, the output being about 130,000 pounds of refined copper daily. The copper matte from the stacks is taken by electric haulage to the converters where it is blown up to 99% blister copper, containing a small amount of gold and silver. No concentrator is connected with the Calumet & Arizona mine, as all the ore is suitable for smelting. The blister copper is shipped to New York, where it is refined by electrolytic process.

The Calumet & Arizona mines have recently absorbed a number of other properties in the vicinity, and it now constitutes one of the largest copper-producing concerns in Arizona.

### Dredging at Oroville, Cal.

TO THE EDITOR:—In your issue of March 4 R. H. Postlethwaite, in commenting on that part of the annual report of the Oroville Gold Dredging & Exploration Co. relating to the per cent of the prospect value recovered by our dredger, has asked for further information as to what equivalent diameter was used in calculating the results of our original prospect.

We used a diameter of  $6\frac{1}{4}$  inches. This is a mean diameter between 6 inches and  $7\frac{1}{2}$  inches, or the inside diameter of the pipe and the outside diameter of the drive shoe. A drive shoe after being used a short time wears down to a cutting diameter of  $6\frac{1}{4}$  inches, all the material within the cutting edge being forced into the pipe. Of course, to be absolutely accurate, one should base his calculations on the mean diameter taken from the measurement of the drive shoe before and after each drill hole, but this is an accuracy which is not justified by this method of prospecting.

As an independent method of determining our prospect values, and also as a check on the above method, we measured all the material taken from the prospect holes. These two methods of determin-

ing the prospect value were applied to 150 prospect holes, with the result that they checked very closely with one another.

It is interesting to note that the value of a prospect hole as figured on a basis of  $6\frac{1}{4}$  inches diameter corresponds closely with the value as computed by the empirical formula given by Mr. Postlethwaite.

The per cent of the prospect value recovered with a dredger depends upon how closely the ground is prospected. The more holes that are drilled the more nearly the prospect value will come to the actual value of the ground, and the more nearly the per cent of the extraction will approximate the real efficiency of the dredger. I know of an instance where a test was made by drilling 22 holes in an acre. A dredger of the same type as ours on working out this acre obtained 95% of the prospect value.

The extraction of 74% of the prospect value by no means represents the efficiency of the dredger. Tests made of the tailings from the stern of the dredger show that the saving is much better than 74%.

However, it is interesting to note that a dredger operating for two years dredged 22.62 acres which showed a prospect of 1 hole per acre and extracted 74% of the prospect value of the ground.

C. H. MUNRO.

### THE PROSPECTOR.

The mineral sample from Bearmouth, Mont., is coal, variety, lignite. The woody fiber is still visible in portions of it. There is an admixture of clayey matter and iron sulphide also present.

The steel gray soft mineral, with black streak, from Del Norte, Colo., is pyrolusite, a portion of which occurs as crystals in botryoidal masses. This mineral frequently occurs as a pseudomorph after other minerals. The crystals in this case are cubic.

The rock samples from Kichner, B. C., are: No. 1 is greenstone (diabase). No. 2 is evidently a silicified dike rock of some kind; it contains a little copper glance and copper carbonate. No. 3 is a much altered dike rock, now consisting of silica coated with iron oxide. No. 4 is a siliceous felsite; it contains veinlets of iron sulphide. No. 5 is a greatly altered dike rock, possibly one similar to No. 1. On one side appears several incrusting minerals, viz., velvety black and brown iron oxide, crystallized calcium carbonate, and the brilliant sub-metallic soft crystals are iron stained margarodite (hydrous mica). Mine water carrying copper in solution acts in the manner described as occurring at the mine from which these rocks came. It would be a good idea to lead the drainage water through a series of tight boxes (sluices) in which has been placed a quantity of old wrought iron scraps, tin scraps, old tin cans, etc. The copper in the water will gradually replace the iron, and form what is known as cement copper. This can be collected from time to time, carefully dried, placed in tight canvas bags and shipped. It should contain at least 60% copper.

PERMITS to carry on hydraulic mining in California may be secured, if obtainable under existing conditions, from the United States Debris Commission, Flood building, San Francisco, Cal. When a restraining dam that has been built under direction of the Debris Commission is filled by tailings, it is the duty of the miner to either build the dam higher or quit mining. The theory that the commission should look after it is not recognized by the commission, and if the miner continues after his pond is filled and the debris passes over the top of the dam, the commission is likely to revoke his permit. It is much easier to get a permit in the first place than to get one renewed after having been shut down by the commission for breach of good faith.

# Mining and Metallurgical Patents.

PATENTS ISSUED MARCH 7, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

ROCK DRILL.—No. 783,032; C. G. Foote, Denver, Colo.

Combination with casing, of cylinder mounted to rotate therein, cylinder being hollow, power spring located in cylinder, latter being provided with cam, hollow drill holder entering hollow of cylinder and having its axis in line with axis of cylinder, drill holder being engaged by cam of cylinder as latter is rotated, whereby drill holder is forced rearwardly against power spring and released, recoil of spring acting to throw drill holder forwardly, causing drill to strike rock with necessary force.

MINER'S PICK.—No. 784,044; M. Hardsocg, Otumwa, Iowa.

Tool, comprising stem formed with recess, pick formed with grooves on one face and mounted in recess, projections on stem seated in grooves of pick, and wedge blocks mounted in stem, one of blocks contacting pick and other stem, wedge blocks formed with oppositely inclined faces in mutual contact and arranged for opposite rectilinear movement for expansion against pick and stem respectively.

VALVE FOR ROCK DRILLING MACHINES.—No. 784,320; J. E. H. Grose, Germiston, Transvaal, South Africa.

In rock drilling machine, in combination, cylinder A and piston B arranged therein, valve chest F on cylinder formed with ports 9, 10, 11, 12, 13 and 14, valve 4 arranged in valve chest F formed with pistons 5, 6, 7 and 8, cylinder being formed with port

17 and holes 16 placing port 17 in communication with interior of cylinder, port 17 communicating with port 14 in valve chest, port 22, groove 23, ports 24 and 23 placing interior of cylinder and main supply port 1 in communication with end of valve chest, ports 18 placing center portion of cylinder in communication with exhaust port 15, ports 19, 20, 20' and 21 placing interior of cylinder and main supply port in communication with other end of valve chest, ports 19 and 22 being controlled by piston to alternately close ports to exhaust 15 to effect reversal of valve 4.

DUMPING CAR.—No. 784,105; W. R. Cliffe, Harrisburg, Pa.

Combination in car of tilting car box having discharge opening, movable door closing opening, arms pivoted to car box and connected with door, bell crank lever connected to car box and coacting with door, whereby movement of car box opens door, hand lever suitably supported, and pivoted connections between hand lever and car box, whereby movement of hand lever tilts car box to dump same and simultaneously opens the door.

ROCK DRILL.—No. 784,173; C. T. McCormick, Fredericktown, Mo.

In drill, combination with cylinder open at both ends and provided with partition, of piston rod passing through partition, piston carried by rod at each side of partition, piston rod being of less diameter than pistons and projecting beyond one of pistons through one of open ends of cylinder, and means for exhausting motive fluid from spaces between pistons and partition and discharging it into open ends of cylinder.

MACHINE FOR CONCENTRATING MINERAL ORES.—No. 784,146; G. R. Duncan, Three Rivers, Canada.

In concentrating table, combination of pulp feed, wash water supply and dropping pan situated upon

area traversed by concentrates in passing to ore box and across which wash water flows to tailings box and adapted to disturb wash water and settled material beneath.

STONE CHANNELING MACHINE.—No. 784,268; C. M. Lyman, Rutland, Vt.

In stone channeling machine, combination of upper slide having means for clamping gang of drills thereto, lower slide, feed screw in threaded engagement with upper slide and swiveled to lower slide, hand operable rotary member through which feed screw passes, screw being provided with longitudinal keyway and member being provided with key to fit keyway, suitably associated upper and lower levers, lower lever being operatively connected with lower slide, and means for vibrating upper lever.

APPARATUS FOR CYANIDE TREATMENT.—No. 784,120; E. L. Oliver, Oakland, Cal.

Apparatus for cyanide treatment of gold and silver bearing materials, comprising tank, open-topped pipe rising within and opening directly into upper portion of tank, lower end of pipe having communication with lower portion of tank, connection from source of compressed air communicating with lower end of pipe; anode and cathode plates within tank; and suitable electrical connections to plates.

MAGNETIC ORE SEPARATOR.—No. 784,502; L. G. Rowand, Camden, N. J.

In magnetic ore separator, combination of conveyor belt adapted to convey material to be treated, of magnets above and below belt, pole pieces of opposite magnets being in proximity to conveyor belt, and discharging belt passing over and beyond and at angle with conveyor belt, discharging belt being interposed between conveyor belt and one of magnets, and belt interposed between conveyor belt and other magnet and extending parallel with discharging belt.

## MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

### ALASKA.

The Leland Dredging Co. is having a large dredger built, to operate on Solomon river, in the Bonanza mining district, Seward peninsula.—An English company has been formed to operate in the upper Kougrok mining district, in the western part of Seward peninsula. They will build a 40-mile ditch and lay 34 miles of steel pipe.—It is thought that the source of the gold of Ophir creek has been discovered in a large ledge of free-milling gold on the head of Crooked creek.

The Fairhaven gold placers of Seward Peninsula are described by F. H. Moffit in bulletin 247 of the United States Geological Survey. This region occupies the northeastern portion of Seward Peninsula and comprises a little more than one-quarter of its total area, or 7500 square miles. It includes the whole of the Fairhaven mining precinct, except that which lies east of Buckland river, the eastern portions of the Goodhope and Kougrok precincts and the northern part of the Koyuk precinct. It is limited on the west by the north-south ridge, extending from Baldy mountain to Devil mountain, and on the east by Buckland river. Its northern boundary is formed by the Arctic ocean and Kotzebue Sound, and it extends southward to the Bendeleben mountains and lower Koyuk river. The northern part of Seward Peninsula is characterized by general low relief and monotonous topography. This particular region is inclosed on three sides by more or less continuous ridges. The drainage is not simple, part of it reaching the Bering sea by various ways and part the Arctic ocean. The placer gold field in that portion of Seward peninsula which lies to the south of the eastern extension of Kotzebue sound is 40 miles long and 20 miles wide, and is surrounded by low moss-covered hills that are natural breeding places for mosquitoes and black flies. The gravels of this field have yielded \$415,000 in the three years beginning with the discovery of gold in 1901 and ending with the season of 1903. The chief producing streams, in the order of their output during those years, are Candle creek and Immachuk river. The Candle creek gravels are the richest that have yet been discovered in this field. They have been the most vigorously exploited, with the result that about three-fourths of the total output of the region has come from this one stream. In the Immachuk region gold has been found in greatest amount on the Immachuk itself, but it has also been obtained from several of the tributaries, especially Old Glory and Hannum creeks. Cunningham creek, Nelson gulch, American creek and Pinnell river have produced still smaller quantities. In addition to these localities Bear creek, a tributary of Buckland river, and Alder beach, nearly 10 miles west of Kiwahik, have a small gold output amounting to \$20,000, equally divided between the two. The gold-bearing gravels, with the exception of those on Bear creek, are of local origin and are derived from the decomposition of schists, through which the gold is disseminated in fine stringers and veins of quartz. The concentration of the heavy metal has been brought about by the action of water currents, which have separated it from a vast amount of rock material and deposited it where it is now found. Coal of inferior quality has been reported from a number of localities in this region.

The Alaska-Detroit Co. are operating at Windfall under the management of Thomas Ellis, who is putting in a hydraulic elevator.—Engineer Geo. Otterson of the Mansfield Co. has taken men to McGinnis creek, near Juneau. A small hand drill, with power from a compressor, will be used to huddle the boulders this season, and a heavy head of water will be used.

### ARIZONA.

#### Graham County.

The Cuprite Copper Co., of Columbus, Ohio, is said to have started work at its mines near Metcalf under the direction of F. C. Alsdorf.

#### Mohave County.

The mill of the Blue Ridge M. Co., east of Vivian, has been started.—The contractors on the St. Louis mine at Cerbat have begun work. T. R. Garnier is superintendent.—L. D. Godshall, J. Geller, A. C. Godshall of Lansdale, Pa., W. G. Bonnevill, C. Ziegenfuss, H. K. Hartzell, M. T. Ochs of Allentown, Pa., and R. E. Wilson of Chicago have been at Cerbat in the interest of the Arizona-Mexican M. & S. Co., regarding the possibilities of building a smelter.

#### Yavapai County.

The Bunker Hill M. Co., 14 miles from Prescott, have reached ore after driving their tunnel 1250 feet. It will be driven 200 feet farther, when Superintendent Julius Moro expects to put up a reduction plant.—It is reported that a 60-ton roller process quartz mill is to be placed on the Rincon mine, south of Congress.

The Octave mine and mill at Octave have been closed.—The Anderson Metals Extraction Co. has commenced work on the foundations for eleven cement tanks at McCahe, for its cyanide plant to work the tailings produced by the Model G. M. Co. mill. These tanks will be 43 feet in diameter each and 4 feet high.

### CALIFORNIA.

#### Amador County.

W. C. Dixon of Colorado has bonded from F. M. Potter of Plymouth mining property north of Plymouth belonging to Potter. The agreement requires Dixon to put up a 10-stamp mill and sink a shaft at least 500 feet deep on the claim.

The tailings from the Voorheis chlorination works at Sutter Creek are again being tested by Harrah Bros. of Oakland.—It is reported that twenty stamps of the Zeila mill at Jackson have been started.

#### Butte County.

Cement brick factories are to be built at Chico and at Auburn, Placer county.

#### Calaveras County.

(Special Correspondence).—At the Union copper mine at Copperopolis the foundations for the steel head frame are complete, but the steel for its construction has not yet arrived at the mine. Superintendent G. McM. Ross states that construction of the new smelter plant is also progressing satisfactorily, though it will be some time before the work is completed. Development of the mine is progressing, and by the time the reduction works are ready the mine will be in condition to supply a large tonnage regularly.

Copperopolis, March 13.

The shaft of the Sultana mine at Angels Camp is being repaired and the machinery put in condition to resume work.—The Utica M. Co. will discontinue the chlorine plants east of Angels and ship all the sulphurets of the company's mines to the Selby Smelting Works for treatment, claiming that the sulphurets can be worked cheaper there than they can be handled in the company's own works. An aerial tramway is being built from the Stickle mill to the Sierra Railway depot.

#### El Dorado County.

Superintendent Spech of Oroville is unwatering and opening up the Church mine, near El Dorado.—At the Clipper quartz mine, above Placerville, H. G. Kopikus is sinking prospecting shafts.—It is reported that the Jasper mine, near Jurgens, is to be started.—At the Pyramid mine, near Rescue, Superintendent John Bluett has thirty men and three machine drills at work.

The Union gravel mine, on Port Hill, is running.—It is reported that the Santa Claus mine, in Greenwood district, has closed down.—Work has been resumed at the Alpine mine, near Georgetown.—W. S. Hickman, A. M. Presby, G. Wentworth and A. Orelli have started work on the Hanson mine, north of Georgetown. A 2-stamp mill has been brought down from the Little Gem mine, at Josephine.—Superintendent Shurtliff of the Monte M. & P. Co., near Jurgens, says that the company will start to build the new flume and ditch for the electric power plant at the Monte mine as soon as the surveyors are through.—J. W. Jurgens & Sons are sinking a new shaft at the Mammoth mine. They are down 35 feet and have a 34-foot vein.

#### Fresno County.

(Special Correspondence).—The court has ordered the receiver of the Copper King mine at Letcher to start operations, its decision being based upon the report of W. J. Adams.

Letcher, March 15.

#### Nevada County.

It is said that J. Martin, J. E. Doolittle, J. H. Hammond, E. A. Forbes and others have bonded all the copper mines near Spenceville along the 20 miles of the route surveyed for the electric road connecting Marysville and Grass Valley.—The Lindsay quartz mine, near Maybert, has been bonded to H. Kahler, superintendent of the Grey Eagle, who will open up the Lindsay this spring.—The new gravel washing plant at the Banner gravel mine, near Nevada City, has been started.

Work has been commenced at the Curnow mine, at Badger Hill, near Nevada City, which was recently bonded by P. Deidesheimer. Three shifts are sinking a perpendicular shaft.—The Murchie mill is being put in shape and will soon be ready to commence crushing ore.

The report of the North Star mine shows that in 1904 the North Star mine produced \$781,273.34, at a current operating cost of \$317,933.53 and an operating profit of \$463,339.81. During the same period \$273,615.02 was spent—notably, development \$129,502.38, improvement \$123,384.14, property purchase, \$15,885, and sundries \$4,843.50—reducing the cash profit to \$189,688.79, from which sum there have been paid two dividends, amounting to \$141,691.50 and leaving a remainder of \$47,997.29 to be added to the cash surplus, which, with interest, etc., increases that sum at the end of 1904 to \$273,055.39. The current expenses amounted to 40.7% (40.7 cents being the cost of a dollar produced), leaving 59.3% as operating profit. The above stated outlays for capital accounts and sundries amounted to 35.02% of the total product, leaving 24.28% as net cash surplus, available for dividends. The total output for the North Star mine (not including Gold Hill) during 1904 was 47,447 tons of ore, yielding \$773,215.81 (\$16.296 per ton), costing for all operating expenses \$313,151.26 (\$6.60 per ton) and leaving an average profit of \$9.696 per ton. The development accounts of \$129,502.38 include \$29,126.10 spent in prospecting in the Gold Hill mine, now suspended without definite, or, so far, very encouraging results. The larger part of the sum charged to development has been spent in the North Star mine and wholly in the Central shaft workings, in building the main incline, extending the openings of the mine and developing ore. The company spent \$64,559.26 on the new mill and cyanide plant at the Central shaft. The total cost of the mill and cyanide plant at the end of the year amounted to \$91,005.74. The mill commenced operation in August and has since been working efficiently. During the latter part of the year the old mill was thoroughly overhauled and renovated. Both 40-stamp mills are working at full capacity, crushing 7000 tons per month. The disbursement account shows that the operating expenses of the North Star were \$114,649.20, Central shaft \$110,021.45, North Star mill \$17,244.17, Central mill \$8749.91, Gold Hill mill \$2877.33, sulphurets \$14,331.53, cyanide plant \$6567.26, bullion \$1728.18, miscellaneous \$17,760.70; total \$294,409.73. Development expenses were: Central shaft \$100,876.28, Gold Hill \$29,126.10; total \$129,502.38. Improvement expenses were: North Star \$16,024.81, mill \$16,391.81, Central shaft \$15,430.24, Central mill \$50,060.69, North Star cyanide plant \$8644.22, Central cyanide plant \$14,498.57, residence \$2333.80; total \$123,384.14. Property purchase expenses were: Irish American \$16,330, Kitto deed \$100, Gold Hill \$455; total \$16,885.

#### Placer County.

At the Hidden Treasure mine, at Bullion, Superintendent H. T. Power has been sinking an air shaft to connect with the main tunnel, but has encountered a large amount of water, which makes sinking difficult. Consequently, a boring machine has been bought to bore

a hole to the main tunnel, whereby the water can be drained off.—The Azelia M. Co., at Blue Canyon, is running a 400-foot tunnel and will upraise to strike the main channel.—Gravel has been struck at the Strawberry mine, at Monona Flat, near Iowa Hill. J. Watts, Sr., is the principal owner.

#### Shasta County.

The United States has obtained an injunction from the United States Circuit Court against the Mountain Copper Co.'s operation of the smelting plant at Keswick. The Government's claims were that the operation of the smelting works at Keswick did irreparable injury to the vegetation on various lands owned by it in the neighborhood. The Mountain Copper Co. contended that the damage done was slight and that the granting of the injunction asked for would ruin its business. Incidentally to the pleading of the case it was brought out that the fumes complained of by the Government would, if condensed, make 700 tons of sulphuric acid a day—three times the amount used in San Francisco in the same period. The contention that the fumes should be condensed and vegetation saved was opposed by the defendant company on the ground of impracticability. It was asserted that if the acid were made at a great expense the only way of disposing of it would be by dumping it out at sea, at still greater expense. The Mountain Copper Co. has time in which to get a stay of the injunction, and will likely do so by putting up bonds to cover all damage. The company has now started a plant at Port Costa on the bay shore.—After keeping armed guards for two years at a gate it put up at Iron Mountain during the strike in the fall of 1902, and after fighting in the courts in Shasta county for two years to establish its right to maintain the gate at the entrance to its mining ground, the Mountain Copper Co. has voluntarily thrown open the gate and withdrawn the watchmen.

#### Siskiyou County.

Superintendent Addison of the Medina G. M. Co. has started machine drills to drive a 1500-foot tunnel under the old works of the Johnson mine at Oro Fino, being worked by the Medina G. M. Co. The 150-foot crosscut tunnel has opened up the Johnson ledge. The mill is running with ore from the Corson & Krandle mine.—It is reported that J. Hamilton transferred a half interest in his mine at Oro Fino to a party from Spokane, Wash., whereby the parties agree to build a stamp mill within sixty days. The machinery will be run by electricity.—The Gardner & Eastlick hydraulic mine at Oro Fino has plenty of water for the elevators and is running night and day.—A. C. Brokaw & Co. has started a tunnel on the Advance mine on China gulch.—The Morrison & Carlock mine at Quartz valley is to be equipped with a new plant for sinking on the vein 200 feet. The 10-stamp mill is being run continuously.—Moxley & Burton have stopped work on their quartz ledge, near Oro Fino. They expect to resume work shortly on a new tunnel site to tap the ledge by crosscut 150 feet from the apex. A shaft has been sunk 110 feet.—The new mill of Harris Bros. & Bassford on Taylor creek, near Oro Fino, is ready to start.

#### Trinity County.

The United States Geological Survey has set aside \$25,000 for the purpose of making a thorough and systematic investigation and exploration of the platinum deposits in Shasta and Trinity counties, and work will be begun at once. Josephinite, another mineral found in very few places, will be looked for under the appropriation just made.

#### Tuolumne County.

Work has been started at the Mazepa mine, near Stent, by Superintendent T. E. Martin.—The hoisting plant of the Gagnere mine, near Tuttle town, has been taken to Calaveras county.—The Providence Con. M. Co. of Tuolumne have bought the Bully Hill quartz claim from F. W. Cook, the Dividend from H. Anderson and the Southern Cross from J. E. Beckwith.

The Champion mine, 1 mile north of Coulterville, has been bonded to C. E. Van Meter, who has started unwatering.—The new Calico mine near Tuolumne is to put in a new hoist. Sinking will be resumed.—The force on the New Tonopah, near Pine Log, has been increased.

The 10-stamp mill of the Los Angeles mine, on the Tuolumne river, below the Mohican, has been running steadily since Feb. 16.

### COLORADO.

Colorado produced \$2,617,649 more gold in 1904 than it did in 1903, according to the figures of Commissioner E. L. White of the Bureau of Mines. In 1904 the gold production in Colorado was 1,171,892 fine ounces, valued at \$24,223,007. For 1903 it was 1,045,252 fine ounces, valued at \$21,605,358. Silver produced in 1904 amounted to 12,960,777 fine ounces, with a value of \$7,416,156; for 1903, 13,245,483 fine ounces, valued at \$7,679,710. The total value of the precious metals mined in the State during 1904 was \$40,783,074; for 1903, \$33,373,099. Lead produced in 1904, 107,546,850 pounds, valued at \$1,624,514. Copper, 9,401,913 pounds, valued at \$1,205,607. Zinc, 64,976,235 pounds, valued at \$3,313,787.

#### Boulder County.

It is reported that the United States Gold Corporation has made a strike of rich molybdenite gold ore in their properties on Arapahoe peak, 6 miles west of Eldora.

#### Clear Creek County.

W. Clair and J. Barker have struck mineral on the Barker claim on Republican mountain, near Silver Plume.—The shaft of the Barmettler & O'Connell lease on the Frostburg lode is 50 feet deep. The shaft is passing through a large body of ore, and, after sinking 50 feet more, levels will be started to open the ground for stopping.—Stevens & McGrath have twenty-five men on the Mendota property, which they have under lease in connection with the mill.—The Silver Plume Board of Mines and Trade has elected C. S. Desch, president; W. H. Stephens, vice-president; W. J. Guard, secretary; C. I. Burt, assistant secretary; A. B. Clark, treasurer.

The Argentine tunnel of the Waldorf M. Co. of Georgetown is in 3800 feet and has cut 44 veins, from 30

of which shipments can be made. Very little drifting has been done on any of these veins. The Commonwealth vein will be cut a depth of 700 feet below the upper workings. This tunnel will also cut the Johnson, Wheeling, Independence and Whendon lodes at an average depth of 1400 feet below the upper workings, and when complete, making connections with the Stevens, will be 9200 feet long and will cut 95 known veins. A new air compressor has been put in at the mine and the power for running the same is furnished by the United Light & Power Co. Two large water Leynor power drills and three small drills are in constant operation in this tunnel. — The Tohin tunnel is 600 feet higher up the mountain than the Argentine tunnel, and, according to the report of Superintendent Tingle, will, within four months, cut the ninth level of the Stevens mine. The purpose in starting this tunnel was to reach the Independence vein, which has produced large quantities of high-grade ore, and when completed will furnish good air to the entire Waldorf property. — E. Wing & Co. are operating a contract on the Kittle Ousley, near Georgetown, and have a body of ore and quartz 4 feet wide. — The Waldorf Co. will build a 50-ton concentrating mill at the mouth of the Argentine tunnel.

President Seeman of the Yankee Con. Co. at Lombard is calling for bids on the new Lombard shaft house. A 100 H. P. boiler, an air compressor and air drills have already been purchased and will be hauled up to the mines from Yankee. The company will build its own assay office. The milling facilities will be increased.

#### Freemont County.

(Special Correspondence).—G. W. Brown & Co. have started their 50-ton cyanide plant working over the dump at the old National mill. It is estimated that the dump contains 20,000 tons. — The oil industry is on the increase in this section. The oil field at this place which has been developed is 4 by 6 miles, and is in the Arkansas valley. There are two refineries — one is controlled by the United Oil Co. and the other by A. R. Gumaer. The United Co. is the only one buying from outside parties. This company purchases the crude oil at the wells and pipes same to the refinery. It is estimated that at present there are 2500 barrels crude oil produced in the district each day. Several independent companies are preparing to start operations within the next 30 to 60 days. The Blaney Oil, Gas & Refining Co., which has a lease on State land, will start work in a few days. A royalty of 10% is paid to the State. The specific gravity of the oil produced in this field is from 30 to 32. On Feb. 1 the price on crude oil was reduced from 90 to 80 cents per barrel. It is understood that lubricating oils are not manufactured here. The main products are kerosene, benzine, gasoline and distillates. After the various illuminating oils have been taken out of the crude oil the residuum is used mainly for fuel. Occasionally a well commences to produce when only 1600 feet down, but as a rule the wells are 2200 to 2300 feet in depth. — The Union and Dorcas mills are receiving all the ore they can handle from the Cripple Creek district. Florence, March 12.

#### Gilpin County.

The Empress M. Co. has started the Empress mine north of Lake View, in the Central district, under the management of C. H. Karns. A new shaft building, 25x54 feet, is being built, and a 35 H. P. hoist put in. The main shaft is down 400 feet. — The Justice mine in lower Russell district is being operated under a lease and bond by J. F. Stanish. — The Black M. Co. are operating under lease and bond the Iroquois mine, at the junction of Willis and Russell gulches, in the Russell district, under the management of H. Rohrer of Denver. The company has been operating the property for three months and has put up a shaft building and a steam hoisting plant. — C. O. Richards has charge of operations at the Chase mine near Russell.

#### Summit County.

The Abundance M. Co., on Mineral hill, near Breckenridge, will sink the shaft deeper and run a crosscut from the shaft to the side lines. J. G. Goodier is manager and T. S. Davidson superintendent.

#### Teller County.

A compressed air motor is to be used in hauling cars from the Morning Glory lode, recently opened in the northern extremity of the El Paso property, on Beacon and Guyot hills, Cripple Creek. The stopes in the new shoot are being blocked out.

The Little Giant M. & M. Co. is putting up a mill and cyanide plant in Pony gulch, 3 miles west of Cripple Creek. — A lease on the Triumph claim, near the summit of Battle mountain, Cripple Creek, has been leased to S. S. Bernard of the El Paso, D. Bernard and J. S. Osborne. The lessees are preparing to install a hoisting plant and sink deeper.

J. H. Hobbs of Colorado Springs has a lease on the Orpha May Nos. 1 and 2 of the Stratton estate at Cripple Creek and has commenced work. — Briggs and associates, who are operating under lease the south end of the Dante property on Bull hill, Cripple Creek, will prospect their territory through the lower Trail tunnel. The lessees have made arrangements with the United Gold Mines Co. to drive the tunnel 100 feet, which is the distance from the Dante line at the present time. By doing this amount of work the lessees are to have the privilege of hauling their ore and waste through the tunnel free during the life of the lease. — Sinking has been resumed in the Lonaconing shaft of the El Paso Company at Cripple Creek.

On the Gold Bond mine in the Caledonia Hill district, Cripple Creek, R. P. Russell is straightening the Sweet shaft preparatory to continuing it to the 400-foot point. — S. McDonald, superintendent of the Henry Adney, the Strong and the El Paso King, has leased property below the Caledonia, near Cripple Creek, and is putting down a 300-foot shaft.

### IDAHO.

#### Blaine County.

W. Deehle is working mining claims 2 miles north of Garfield gulch, near Muldoon. The claims of the Muldoon M. & M. Co. are being worked by J. Peterson. — The Northwestern Co. is driving a 2000-foot tunnel to open up its mines. Foreman J. Gilson has run it 330

feet. Manager Tustin has laid out the site for the 100-ton concentrating mill to be put in.

#### Boise County.

It has been found that the ores of the Pearl district can be cyanided and a number of companies intending to put in concentration plants have changed their plans. The Idaho G. M. D. Co., M. M. Makoever of Boston, secretary, is now excavating for a 100-ton plant at the Osborne mine. The Black Pearl Co. is also putting up a 150-ton plant.

#### Canyon County.

On Payette river, below the junction with Deadwood fork, a big tunnel has been nearly completed through a basaltic cone, to divert the river, leaving 2 miles of the old channel bare. A 5-foot wooden stave pipe will carry the water 1 mile to give a 62-foot fall for a hydro-electric plant to generate power for Boise and the surrounding country. At first the tunnel was 16 feet wide, 12 feet high in the arch and 9 feet high at either wall. Later the width was made 20 feet, and now the management is enlarging to 20 feet width. L. Bunch is manager. In driving the tunnel through the rocky cone serious flows of hot water were encountered. The 2 miles of the old channel exposed by the tunnel will be placed by means of hydraulic pressure obtained from the Payette. Three-quarters of a mile below the tunnel, along which distance the big pipe is to be erected to give better fall for the power plant, will be washed part of the year, but in flood times will not be available, as the pipe will not handle the entire stream. The new plant is estimated to furnish 10,000 H. P.

#### Elmore County.

E. W. Fisher, general manager of the Daisy and Overlook properties at Neal, near Boise, has started the mill. The Daisy shaft, now down 200 feet, will be sunk another 100 feet. A crosscut tunnel is being driven to cut the Daisy ledge west of the shaft. The tunnel is in 130 feet. Work will soon be started on a small cyanide plant to test the Daisy ores.

#### Idaho County.

The bucket elevator dredger 2 miles below Warren is to be started by Manager Alexander as soon as the ground is thawed. — On Shesler creek, near Warren, Herb. Cook is ready to begin work, as is also Geo. Smith on Euston creek. — At Grouse creek, near Resort, 15 miles west of Warren, the Golden Rule hydraulic placers are ready for work. — F. H. Brown of Colfax, Wash., will work four claims north of Warren. He has put up a 3-stamp mill and will employ a large force. — J. B. Brown of St. Louis, leasing the Springfield group, near Warren, will put in a cyanide plant. — Chas. De Grundy, superintendent of the Keystone mine, 4 miles south of Warren, will sink the main shaft 150 feet.

#### Latah County.

A rich strike is reported to have been made at the White Cross mine, on Moscow mountain, 7 miles northeast of Moscow. S. Tinker of Murray has started the mill.

The Idaho Legislature has appropriated \$40,000 for the school of mines at Moscow. A. S. Miller, instructor in mines, will supervise the construction of a complete mining and metallurgical laboratory.

#### Lemhi County.

O. P. Chisholm of Bozeman, Mont., and W. C. & C. E. Morris of Pony, Mont., are organizing a company for the operation of their claims in Beaverhead county, Mont., and Lemhi county, Idaho, and expect to drive a tunnel from one State to the other in an endeavor to tap the lead.

#### Owyhee County.

A second ledge has been cut in the War Eagle tunnel, near Silver City. It was opened in a crosscut driven from the upraise that is being made to open the old works. The vein is 5 feet wide and the walls are well defined, but at the point where it was cut by the work it shows low values. H. L. Woodburn, the general manager of the company, is at the tunnel making an inspection of the property.

#### Shoshone County.

The Golden Chest, near Murray, being worked by M. and J. H. Hayman of New York, is running a tunnel 2700 feet long, to get out the ore without hoisting. It is reported that the mill will be enlarged from 20 to 50 stamps. — The Bear Top Co. is completing a 150-ton concentrator which may be started within a month. It should start within six weeks. The 1-mile tramway is complete. — The Mascot M. Co., promoted by C. S. Chrysler, has started work with its dredge on Trail creek.

The Gold Hunter M. Co., at Mullan, has resumed work with sixty men. The mill was recently overhauled and partly reconstructed and is giving satisfactory results. The company is figuring on putting in electric power to operate the mill. The new lower tunnel has been temporarily discontinued. — The Morning mine, at Mullan, is working 250 men.

J. A. Ward, of Thiard, Idaho, says that the Wake Up Jim gold mine on Trail gulch will operate this summer. A 10-stamp mill and cyanide plant will be put in. The property is on the divide at the head of Trail gulch between Wallace and Murray.

#### Washington County.

The Iron Springs M. Co. at Iron Springs, 5 miles north of Black Lake, will build a 100-ton cyanide plant this summer. D. C. Nevin reports that a large body of high-grade ore has been opened up. The company owns the Iron Springs, Pactolian, Holbrook and Kearns groups. The property carries a wide fissure zone of siliceous, schistosity formation, impregnated with auriferous pyrites in walls of greenstone and diorite. — It is reported that the Ladd Metals Co. has purchased the entire holdings of the American M. Co. in the Seven Devils. The Ladd smelter at Landore has been temporarily closed down.

### MONTANA.

#### Beaverhead County.

At the Indian Queen property at Farlin the Amalgamated Copper Co. has built new engine and hoiler houses, a new blacksmith shop and other buildings, put in a 80 H. P. engine and hoiler, an air compressor and

two machine drills. The old company had run a tunnel into the hill on the Indian Queen 500 feet and 300 feet from the entrance had sunk a shaft 150 feet. At the bottom of this shaft the new company has run a tunnel 150 feet and are now raising to the level of the tunnel, and when this level has been reached a station will be made in the granite and hoisting machinery put in. Sinking will be continued to a depth of 500 feet, a station being made every 100 feet. There are thirty-five men at work.

#### Fergus County.

The past winter's operations at the Yogo sapphires mines have been the most successful yet known there. An immense amount of vein matter has been taken out, and the number of gems contained is larger than ever before, while the sapphires themselves are of higher grade than usual. The London company, which has worked forty months all winter, will increase the number to seventy-five. — The Sweeney company has been successful. The sapphires occur in a dike of trap rock in white and gray limestone. The dike extends for 5 miles and contains occasionally stones as large as five carats. The stones are obtained by means of sluice boxes fitted with Hungarian rifles, the boxes being given a slight pitch to prevent the stones being carried over the rifles.

H. H. Lang of the Kendall mine, at Kendall, is putting in a 150 H. P. electric hoist, a new compressor and station and sinking pumps.

A. Scibler and A. Russi of Kendall have bonded to W. G. Moore of Colorado Springs, Colo., a group of claims in the North Moccasin district, including the Cape Nome, White Elk, Fourth of July, Elizabeth, Bombshell, Powhattan and Sassacass.

#### Jefferson County.

(Special Correspondence). — The Corbin-Wickes M. Co.'s property near Corbin is to be developed, according to J. A. Bender of Chicago, Ill., who claims that he has interested several Chicago capitalists, including W. H. Cribben, C. W. Andrews and C. Bonner. Sections of the district are being prospected with a diamond drill to determine what the ground contains below the depth of the shafts.

Corbin, March 12.

#### Silver Bow County.

(Special Correspondence). — The Butte Copper M. & S. Co. shipped 508 tons of ore from the Dutton mine in East Butte between Jan. 1 and Feb. 19, for which \$10,162.37 was paid. The shaft is down 350 feet. — The Glegarry mine, owned by the Montana Ore Purchasing Co., is in operation under lease. The mine has been equipped with an electric hoist. No attempt will be made to unwater the lower workings, which are down 1000 feet. — The Cambers mine in the eastern section, and owned by the Amalgamated, is yielding 100 tons of first-class ore a day and a good quantity of second class ore. — The Monitor claim, near the Cambers, is yielding from 15 to 25 tons of good copper-silver ore a day. The shaft is 270 feet deep and the work is being confined to the 200 level.

Butte, March 13.

### OREGON.

#### Baker County.

Owing to the early spring, placer operations have begun in most of the camps of eastern Oregon. The snowfall the past winter has been light, but the supply of water depends on the manner in which the snow melts, and the amount of rainfall during the spring months. The Carpenter diggings in Pocahontas district, 7 miles from Baker City, are in operation with two giants. M. Carpenter has charge. — A. D. Cavin, who is associated with W. J. Patterson and F. W. Eppinger of Baker City in the ownership of 160 acres of placer ground at Cow creek, a tributary of upper Burnt river, has been at the placers directing the construction of a bedrock flume 500 feet in length. This has been finished and the placers are ready for operation. — Below the Cavin placers A. A. Groves has drifted on his placers and will operate a giant this season. — F. W. Talmadge, manager of the Oregon M. & I. Co., has been constructing a 9000-foot bedrock flume at the lower end of Sawmill gulch. — Hazelwood & Brown have had a force at work preparing their ground on Eagle creek for operation this season. — The Powder river claims owned by C. I. Slade, Thompson & Small and Miracle & Wallace, will be worked this year. — It is reported that Seattle, Wash., people are going to open up the Rattlesnake diggings to thoroughly equip the property and bring in a plant. — The Connor creek mine and Flick's bar property on Snake river have been in operation a month with two giants each. — The Rye valley and Mormon basin placers will be operated.

M. N. Thompson of Weatherby, Or., general manager of the Granite Mountain G. M. Co., reports that 800 feet of development work has been done by the company and that plans for a mill are to be considered.

The Cyclone M. Co. has bought the Curtis claims, between the Cyclone and Virtue mines, near Baker City, for \$12,500.

#### Grant County.

It is reported that Manager Gibbs of the Copperopolis mine, near Dixie creek, will start building a reduction plant.

A shaft is to be sunk on the Sheridan mine, near Granite. Manager O. C. Wright of Sumpter intends to put on a hoisting plant.

#### Jackson County.

It is reported that I. Ray and A. Houck of Gold Hill have opened up 4 feet of asbestos on Cedar mountain, 35 miles from Gold Hill, on the headwaters of Evans creek.

#### Josephine County.

A. C. Hooper, manager of the Mt. Pitt M. Co. on Jump-off-Joe, will put in a 5-stamp mill. Water power will be used. — H. D. Sluter is operating his placer mine on upper Wolf creek, near Grants Pass. — The Golden Drift M. Co. has completed the pipe line connecting the pump with the four giants at the diggings. The pipe line is 1500 feet long and the pipe is 22 inches in diameter. The water will be pumped direct to the giants, forks in the pipe dividing the stream near the diggings. Four giants will be used. — The main tunnel of the Queen of Bronze mine at Takilma is in 800 feet.

It is reported that the smelter is to be blown in when the roads are opened up.

The Michigan M. & M. Co., of which W. T. Perry of Portland is manager, will spend \$50,000 in the development and equipment of its quartz mines on Applegate river, 8 miles south of Grants Pass. Men are building a mill, shops, quarters and developing the mine. The mill will be supplied with rifles, separators and vanners. The camp is known as Michigan City.

#### Lane County.

(Special Correspondence).—The assay office and transformer room of the Lucky Boy M. Co., at Blue River, were burned down Feb. 12, thus closing the 40-stamp mill. Arrangements have been made to put in a transformer that will allow twenty stamps to start until the new transformer can be obtained from the East. The mines are in shape to keep the whole mill running double shift. Blue River, March 10.

The 4-stamp mill of the Great Northern mine, in the Blue River district, has been started. Teams are hauling ore from the mine to the mill, as the aerial tramway has not been completed.

### NEVADA.

#### Churchill County.

Work on the new cutoff of the Southern Pacific between Hazen and Fort Churchill, connecting the main line with the Carson & Colorado, giving it direct communication with the gold camps of southern Nevada, has begun and will require three months for completion.

#### Esmeralda County.

(Special Correspondence).—The 5-stamp mill of the Mohawk Alpine Co. at Silver Peak has been started. Considerable difficulty has been caused by saline water, not only with the boilers, but also in amalgamating. This is the only mill operating near Silver Peak. The overflow from Tonopah and Goldfield is expected to cause a boom. Lots are being staked off and high prices are being asked for prospects that were not worth locating a few years ago. The Mohawk Alpine Co.'s plant consists of boiler, pump, five 1250-pound stamps, 10-foot amalgamating tables, a Wilfley and Union concentrator. A cyanide plant will be put in later. It is reported that Blair's Silver Peak property is to be reopened, and in this event the mill will be built at the mine, 8 miles from water, and the power supplied from either Owens river or the coal mines at Coaldale, 26 miles north of Silver Peak. At Silver Peak the Cambrian limestones are cut by pegmatitic granitic rock, which changes to pegmatite and quartz veins. The ore appears to be connected with these intrusions. The reported strike 12 miles south of Silver Peak is in some low sand hills, which are said to go \$1 to \$2 per ton of sand. Silver Peak, March 11.

The Douglass gold mines near Sodaville have been transferred to the Van Duzer-Douglass M. Co., who will begin active operations and erect a mill. C. D. Van Duzer is president.

The Western Reduction Co. is building a sampling works and 20-stamp mill on the southern edge of Goldfield. Ten stamps will be in operation within a month. The company has a well 100 feet deep that has already proven its ability to supply 20,000 gallons of water daily. The officers are M. M. Bates president, F. B. Keever secretary, T. C. Woodworth manager and engineer, F. A. Thompson superintendent.

The Douglas and Bounce groups of the Silver Star, 8 miles west of Sodaville, have been sold for \$50,000 to C. D. Van Duzer and associates by E. Grassi, T. Pepper, G. Futtler, D. Robb and W. Douglas. There is a 5-stamp mill on the property, and more will be added.

#### Humboldt County.

The Vulcan mine, 2½ miles from Winnemucca, is shipping to the United States Smelting Co. at Bingham, Utah, low-grade ore to be used as a flux. C. C. Nichols is in charge.

### NEW MEXICO.

#### Dona Ana County.

At Organ an outside shaft 400 feet deep is being sunk on the Stephenson-Bennett with the hope of reducing the cost of raising the ore. The mill capacity is to be doubled. J. I. McCullough is president of the company. The hanging wall is a hard blue limestone and the foot wall is a granite-porphry dike. The ore bodies are chiefly in the lime. The principal minerals are galena, argenticite, anglesite and wolframite.

#### Santa Fe County.

The Golden Cement Co. is completing a concentrating plant to cost \$10,000 near Golden Camp to work the cement placers. The process is to be a dry concentration after crushing the cement. This is the newest part of the placer district. The gravel averages from 25 cents to \$1 per yard of material handled. Scarcity of water has been the serious obstacle in the development of the district. The fineness of the gold is about 920.

#### Sierra County.

Shandon is the name of the new town in Sierra county on the Rio Grande above the mouth of Apache canyon, which is supported by the placers in the Caballo foothills. These mines have yielded \$1000 per month during the past year, the Mexicans doing most of the mining. The Parker Bros. of El Paso have bought several hundred acres of placers in Tiojillo guch, and are installing hydraulic machinery for ground sluicing. The anchor boats and other appliances are completed and are anchored in the Rio Grande, awaiting the arrival of the machinery. A 6-inch pipe is being laid to the reservoir, 2 miles from the river, and with the triplicate pump now being installed water enough can be thrown into the reservoir in twenty-four hours to furnish an eight-hour run. The plant should be in operation by April 1.—Goss Bros. of Salt Lake City, Utah, have leased and bonded the Silva property of 640 acres and will operate it.

### SOUTH DAKOTA.

#### Custer County.

It is reported that work will be resumed on the Extreme on Ruby creek, 3 miles northwest of Custer City, by Superintendent I. Downing. A 10-stamp mill and

cyanide plant have been put on the property.—It is understood that the Le Roy M. & M. Co. will put in a hoist and air compressing plant on its shaft, near Custer City, preparatory to sinking to the 500-foot level.

#### Lawrence County.

The report of W. L. McLaughlin, manager of the Horseshoe M. Co. at Terry, regarding changes in the milling plant during 1904, states that two large tanks, which were used as solution tanks, were moved from above the crusher building back of the mill building and one is now used as a battery solution tank and the other is a barren solution tank. A building 40x72 feet was built over these tanks and two zinc dust presses put in over the barren solution tank; an acid treatment tank and a lead-lined receiver were put in to treat the product and pumps were put in to give a constant head of solution to the classifier; two tanks, 30x14, were moved up in front of the engine room to receive the slimes flowing from the classifiers and allow the clear solution from these tanks to run back to the batteries and to the sand tank, saving pumping. A triplex power pump was connected with the line shaft to pump the solution from the precipitating tanks up through the zinc dust presses. The two zinc precipitating tanks were moved up just below the settling tanks. Two centrifugal pumps were connected with the line shaft to pump the solution from the bottom of the mill up into the battery tank. The three old sump tanks have been changed so that the slimes are given another wash with barren solution and with wash water at this point before they were allowed to run away. A slime press was put in. A new refinery was built near the assay office and contains a drying furnace, cupelling furnace and blast furnace. During the year \$12,472.35 was paid on mill construction, \$8789.88 on mine construction, \$3996.22 on mill improvements and \$2850.93 on mine improvements. The gross bullion returns for eight months during 1904, beginning May 1 and ending December 31, were \$285,757.41. The bullion expense was \$1262.40, leaving net bullion returns of \$284,495.01. There were mined during the year 65,568.28 tons of ore gross, or 60,757.44 tons net. The total cost of mining and milling during that period was \$189,375.80. The average cost of mining was \$1.75 per ton. During December the average cost of mining was \$1.58; milling, \$1.25. This cost was reduced during January. The ore treated in the mill has averaged \$7.22. During December, 1904, the percentage extraction was 73.3.

The Hidden Treasure mine, on Deadwood gulch, has resumed sinking its shaft from 170 feet to 500 feet.—Hoisting has been resumed at the Puritan mine, 3 miles east of Deadwood, after a short shutdown because of water in the shaft. The mill has been enlarged from ten to twenty stamps and an electric pump put in to supply water to run it.

The Custer Peak M. Co. will build a reduction plant at the mine on Custer peak. Sinking has been resumed from the 190-foot level.

#### Pennington County.

It is reported that the Auburn Co. will resume work on its placer bars in Castle creek, above Mystic. Last season the company put in machinery and cyanide vats to catch the very fine gold. The gravel is raised from the pit by an automatic elevator and dumped into sluice boxes with rifles that catch the greater part of the coarse gold. Thence the material is passed over grizzlies, rejecting the coarse material and allowing the finer portion to go through another set of sluices and rifles, at the end of which a 16-mesh screen passes the fine material to the cyanide vats.—It is reported that the Black Eagle mine, in the Hornblende district, 4 miles southeast of Rochford, is to be started.—The Gertie tin mine, near Hill City, is being reopened under the direction of E. C. Johnson. A small tin mill has been put up.—The Mariposa G. M. & M. Co. has been formed to work the Mariposa claims, between Castle and Slate creeks, 2½ miles southeast of Mystic. Chas. Beldin, 816 Nicollet avenue, Minneapolis, Minn., is president and John Wise of Mystic is superintendent. An air compressor and drills are to be put in to drive an 800-foot tunnel.—The Black Hills C. Co. intends to resume work near Rochford.

### UTAH.

#### Beaver County.

The annual report of the Horn Silver M. Co. at Frisco for 1904 shows that there were 15,912 tons of ore produced; of this 522 tons is classed as zinc, 1723 tons of first class, 2452 tons of copper, 8652 tons of crude and 2560 tons of milling. The metals produced from the ores sold aggregated 7,432,855 pounds of lead, 110,541 ounces in silver, 593 ounces in gold, 1,588,287 pounds of copper, 391,676 pounds of zinc. The cost of extraction of each ton of crude ore was \$5.066 and the cost of concentration at the mill was \$1.592. The average value of the first-class ore produced per ton was \$12.02; first-class copper ore, \$28.55; first-class lease ore, \$20.24; zinc ore, \$7.05, and concentrates, \$13.21. The financial statement shows receipts from the sale of concentrates, \$5,890.72; sale of copper ores, \$67,520.47; first-class ore, \$99,553.38; lease ore, \$33,769.24; zinc ore tailings, etc., \$5653.97; net proceeds from house rentals at Franklyn, \$252.50; interest on sundry amounts, \$1793.59; surplus from Frisco store, \$5000, which added to the cash on hand January 1, 1904, of \$51,265.02, makes a total of \$270,998.89. In the items of expense \$80,614.90 was paid out for mine and \$4091.55 for mill operation; \$21,420.70 in royalties; \$33,649.95 in general expense; \$60,000. The treasurer's books showed cash on hand, January 1, 1905, of \$51,890.38, while there were call loans outstanding aggregating \$15,000, and supplies on hand to the value of \$3835.97.

#### Utah County.

The Bonanza M. & M. Co. at West Tintic will be equipped with a concentrating plant. Superintendent C. W. Jones has submitted estimates for a mill to be equipped with rolls, jigs and tables, and the same has been approved.

#### Salt Lake County.

P. H. Hanson of Salt Lake City, who has accepted the superintendency of the Butterfield mines at Bingham, reports that the new Queen mill will be started again. The properties include the Queen, the Eagle

Bird and Northern Chief groups, and are owned by the Conglomerate M. Co., of which G. Lavignino of Bingham is president.

The Bingham Central M. Co. has been formed, with a capital of \$2,000,000, all subscribed, by Samuel Newhouse president, D. C. Jackling vice-president and general manager, C. W. Whitley treasurer, W. M. Bradley secretary. They have started work on claims in the West Mountain mining district.—F. J. Taylor has charge of work on the Jeff Davis tunnel.

#### Tooele County.

T. C. Wiswall of the Greene Reduction Co. says that the plant with which the gold contained in the tailings of the old Marion mill at Mercur is being recovered will go into commission again as soon as the weather shall permit.

#### Utah County.

The Capitol Gold & Silver M. Co. of American Fork has elected R. E. Hunter, president; C. J. Logie, vice-president; J. E. Jensen, treasurer; A. K. Thornton, secretary. They will continue operations on the Gold Blossom mine.—It is understood that the Wyoming mine, in American Fork canyon, which was to resume operations on the 15th of March, will not do so until April 1. Manager G. Tyng is in Texas.

The Clipper & Silver King mine, in the American Fork canyon, will resume operations as soon as the weather permits.

### WASHINGTON.

#### Snohomish County.

The Buckeye Copper Co. has been formed by L. J. Lemley, Columbus Grove, Ohio; J. Coup, Cleveland, Ohio; A. O. Jeffries, Baring, Wash.; E. J. Smith, Cleveland, Ohio, and T. McIntyre, Index, Wash., to work the Index-Independent mine at Index. They will put in air drills and other machinery to drive a new tunnel and continue the old one.—J. J. Habecker, owner of the Wayside mine, near Granite Falls, will put in new machinery.

#### Stevens County.

The Roselle M. Co. has found a large deposit of wolframite on its property in the northern part of Stevens county and is building a 20-ton concentrator to treat the ore.

C. Knutson has taken control of the Great Republic, 5 miles west of Northport, on Sheep creek.

### FOREIGN.

#### AUSTRALIA.

The report of the Broken Hill Proprietary Co. of New South Wales states that the crosscut from the winze from 800-foot level down 115 feet developed a fine ore body 40 feet in width, while there has been only one wall. On the 1000-foot level to the south of McBryde shaft have opened up a fine body of ore 55 feet in width, without walls. Tonnage of ore raised the past half year has exceeded output during previous six months by 19,000 tons, collective tonnage from all sources being 324,535 tons; average, 1800 tons per diem, or 12,482 tons weekly, with satisfactory reduction in working costs. There were 313,543 tons of ore treated by the concentrating plant, mill working well, in every way satisfactory, both with regard to working costs and better recovery of all metals. Result of smelting operations at Port Pirie satisfactory as regards working costs and better recovery of metals, producing 1272 tons pig lead, 38,766 ounces fine silver more than during previous half year. Zinc concentration plant treated 28,000 tons; has a capacity of 600 tons per day of twenty-four hours, in consequence of which, and in order to be to a reasonable extent independent of European buyers, question of the erection of the necessary plant for the manufacture of spelter is receiving special consideration. For this purpose the reserve fund has been increased from £125,000 to £150,000. At the present time the manufacture of spelter is in the hands of only a few firms or companies of limited capacity, therefore the board propose to make ourselves entirely independent of this limitation, and obviate difficulty in the direction of the disposal of our products.

The latest returns for the gold output of Australia for 1904 credit New South Wales with £1,146,000, Queensland with £2,630,000, South Australia with £90,000, Tasmania with £275,000, Victoria with £3,253,000, and Western Australia with £8,425,000, a total of £15,819,000.

### BRITISH COLUMBIA.

#### Boundary District.

For the week ending March 11, the shipments of the Boundary mines were: Granby, for Granby smelter, 12,330 tons; Mother Lode, to B. C. copper smelter, 3040 tons; Montreal & Boston's Brooklyn, 1942 tons; Montreal & Boston's Rawhide, 1681 tons; Montreal & Boston's Mountain Rose, 240 tons; Brooklyn dump to Trail smelter, 130 tons; Montreal & Boston to B. C. copper smelters, 210 tons; Orudenero to Granby smelter, 30 tons; Elkhorn to Trail smelter, 20 tons; Skylark to Nelson and Granby smelters, 60 tons. Total for week, 19,683 tons. Smelter treatment was as follows: Granby smelter, 13,744 tons; B. C. copper smelter, 4324 tons; Montreal & Boston smelter, 3728 tons. Total for week, 21,796 tons. Total for year to date, 172,667 tons. The total shipments for January were 68,074 tons and for February 72,761 tons.

Operations have been resumed at the Winnipeg mine, Wellington camp, after a close-down of sixteen months and the sale of the property to satisfy the labor liens against it. W. T. Hunter, C. D. Hunter, J. Hunter, S. Macy and A. B. W. Hodges have bonded it to the Granby Co. J. Rogers is unwatering the property, so that it can be thoroughly examined and sampled. The mine has a 350-foot shaft. It has a small machinery plant, including air compressor, pumps, hoist, etc., with bunkhouse. A spur of the C. P. R. R. was built to the mine in 1899, and 5000 tons of ore were shipped to the several smelters.

Work has been discontinued at the Senator mine, Summit camp, and the bond on the property thrown up by the Granby Co. The owners are C. Tobiasson and R. Hoffman of Grand Forks.—It is reported that the

Montreal & Boston Con. have taken up the Seattle claim, 10 miles up the North Fork of Kettle river, on a lease and bond from R. Clark and Hay & McCallum of Grand Forks.

Cassiar District.

Extensive strikes of copper and coal are reported from Telqua valley, a tributary of the Skeena river.

Rossland District.

The shipments of the Rossland district for the week ending March 11 were: Le Roi, 3275 tons; Centre Star, 1620; War Eagle, 1380; Le Roi No. 2, 370; Spitzee, 150; White Bear, 405; total for the week, 7200 tons, and for the year, 68,156 tons. F. C. D. Haggard, a director of the Le Roi No. 2, and A. Hill, its consulting engineer, have arrived at Rossland from London to look over their properties. It is expected that they will decide the question of taking up the bond on the Eureka-Evening group, which was bonded to the Le Roi No. 2 last fall for \$175,000. Work has been kept up ever since, and it is said that ore of a good grade has been found. A. McLean, a director in the Velvet-Portland of London, and W. Thompson, consulting engineer for the same company, are to fix the time for the resumption of work on the Velvet-Portland, on which work was shut down about two months ago on account of a shortage of water for the concentrating plant.

CANADA.

The mineral production of Canada for 1904, as compiled from the preliminary figures collected by the Mines Section of the Geological Survey by E. D. Ingall, was:

Metallic Product.	Quantity.	Value.
Copper (b), pounds.....	42,970,594	\$ 5,510,119
Gold.....		16,400,000
Iron ore (export), tons.....	168,828	401,738
Pig iron from Canadian ore, tons.....	68,297	991,880
Lead (c), pounds.....	38,000,420	1,657,420

<b>Total, 1904, all products.....</b>		<b>\$60,343,165</b>

(a) Quantity or value of product marketed. The ton used is that of 2000 pounds.  
(b) Copper contents of ore, matte, etc., at 12.83% per pound.  
(c) Lead contents of ore, matte, etc., at 4.30% per pound.  
(d) Nickel contents of ore, matte, etc., at 40% per pound.  
(e) Silver contents of ore at 57.23% per ounce.  
(f) Oven coke, all the production of Nova Scotia, British Columbia and the Northwest Territories.  
(g) Gross return from sale of gas.  
(h) Includes crude oil sold to refiners and oil sold for fuel and other purposes.  
(i) Zinc contents of ores at 5.100% per pound.

GUATEMALA.

The U. S. Consul at Guatemala reports that the mineral deposits of this republic cover a wide range and are very rich. During the early Spanish occupancy of this part of Central America fabulous quantities of gold and silver were taken from Guatemala. Many of the mines were worked as late as the first half of the nineteenth century, but since that time the frequent revolutions and disturbances have discouraged mining. With the quiet that has reigned for the past six years, and with the outlook, much more interest is being taken in mining properties than for many years. The mining laws provide that in case no work is being done on a mine for a period of two years it reverts to the Government, and can again be acquired as in the first instance. The mining laws in general are very liberal, resembling those of the United States, and the interests of the miners are well protected. Some of the old, rich mines are being reopened, and Guatemala bids fair to attract more attention along this line than Mexico. It is a matter of history that at one time there were 140 rich mines worked here. From one group the mint of Guatemala coined silver to the amount of \$43,000,000, besides what was shipped directly to Europe. Large bodies of lead ore are found that run from 70% to 80% lead, with some silver. These are matters of record, and the mines are not difficult to locate. Gold is quite extensively mined, and copper is said to be plentiful. The mica beds are very extensive, and abundance of first-class mica is in easy reach. As yet but little coal of value has been discovered. Iron ore of a good quality has been discovered, but as yet no practical use has been made of it. The climate where the mines are situated is, in the main, temperate, and the heat seldom exceeds from 75°

to 80° in the shade. The sanitary conditions are fine and the country is considered a healthful place to live. In some parts labor is scarce, and as a general thing native labor is not worth much in mines. It can be had for from 10 to 20 cents gold per day, but that is about all it is worth as compared with the labor of practical miners. For common labor the natives do better.

MEXICO.

Guajajuato.

A 100-ton custom mill is to be built at Marfil for the treatment of low-grade ores. D. V. A. Williams is to have charge of the construction.

Guerrero.

E. D. Lukis, manager of the San Mateo mine at Taxco, has unwatered the shaft, but the flow of water being too great for the capacity of the company's pumps, two 75 H. P. boilers and a No. 9 Cameron pump are being put in, after which shipping will be started.

Jalisco.

The Central M. Co. of Philadelphia, Pa., will put in a cyanide plant at the San Felipe mine in the Hostotipaquillo district. C. L. Beard is manager.

Lower California.

The Evangelina Copper M. Co., of Los Angeles, Cal., is operating in San Julián canyon, near Port Canav, on the Pacific coast of Lower California, in the Santa Caterina mining district, 230 miles below Ensenada. It is the intention to build a 50-ton smelter. The president and general manager is D. R. Wilder of Los Angeles.

Mexico.

The chief veins of the El Oro district are the Chihuahua, San Acasio, La Descubridora and San Rafael. The Amistad consists of 50 pertenencias, through which is supposed to pass the Descubridora and the Chihuahua veins, with three small veins, or vetillas, in between. Two vertical shafts have been sunk and connected below for ventilation. The Amistad Co. is sinking a three-compartment shaft to a depth of 200 meters, when crosscuts will be driven east and west to cut the Descubridora and Chihuahua veins. A double-drum hoist and two boilers, 80 H. P. each, also Cameron station and sinking pumps, have been put in. A vertical shaft is being sunk on the Chihuahua, south of the Amistad, and also upon the Descubridora. Steam hoists and pumps have been put on the properties, and also on the Maria Teresa and Santa Rita. The El Oro M. & R. Co. has its most important mines on the San Rafael vein. The ore of the San Rafael is free milling and suitable for pan amalgamation, the tailings being afterward cyanided. The company has a 100-stamp mill and cyanide plant. It intends to sink a shaft on the Somera No. 1, adjoining the El Oro properties on the west. The Guggenheim Exploration Co. of New York has a 100-stamp mill and cyanide plant on the Esperanza. The Dos Estrellas vein is worked by Compania Minera Las Dos Estrellas, who have an 80-stamp mill and cyanide plant, and intend to add 40 more stamps. The Pleyades, Union and Victoria y Anexas are also being worked.

Sonora.

(Special Correspondence).—The Cananea Con. C. Co. has commenced work on a large reverberatory furnace. A modern sampler and ore bedding system for bedding ore before smelting are to be installed at once. Several Willey tables and vannors are to be added to the concentrator. The improvements will cost over \$500,000. W. Wilkins and associates have sold the Palmarito silver mines in the Mocorito district to northern capitalists for \$125,000 gold. R. McCune, vice-president of the Sonora-Bonanza M. Co., whose holdings are located in the Bocoachi district, was here recently and reports that they have discovered considerable quantities of wulfenite and are preparing to concentrate it. The company is working thirty men and shipping ore to El Paso. Continued heavy rains have greatly interfered with mining operations the past month.—The C. C. Co. turned out something over 5,000,000 pounds of copper during February. Cananea, March 7.

MONGOLIA.

The Mining Journal says that the gold mines in Mongolia are worked by a Russian company, who have obtained a concession from the Chinese Government for the working of minerals in the Tusbutukhan and Tzetzenkhan districts in Mongolia: an immense area, on which, however, so far only two mines are worked—one along the bed of the river Iro and its tributaries, all discharging their waters into the Orkhon—Selenga—Balkal; the other is on the other side of the Yablonovoi mountain range on the River Tiridja of the Amur system. The Iro mine is 140 miles east of Kiakhta, and the Tiridja mine is 100 miles beyond Urga. At the mines there are fairly good roads with stations, and traffic is carried on on horses belonging to the company. The founder and organizer of the enterprise, M. von Grot, had vast plans for the development of the same. It was his intention that the production and treatment of the gold should be done by machinery. He ordered, at great expense, engines, boilers, and all necessary appliances for river dredging, hydraulic works, and a gold-smelting plant. All the machinery and plant was obtained from America, and American engineers were engaged to put up the plant and instruct the local men in the use of the same. The dredge did not work, and the hydraulic works made no progress owing to the deep layers of peat formations in one mine and for want of water in the other. In consequence of these failures, Von Grot reverted to the old primitive method of gold washing, and the Americans were dismissed and replaced by Russians. But this again resulted in failure owing to the bad selection of the staff, not one of whom had any technical knowledge of mining. The result of this was that the business began to decline before it had time to develop. Discouraged by the fruitlessness of all his efforts, M. von Grot at the end of 1903 resigned his position of general manager, and the company appointed another in his place with two assistants, both qualified mining engineers. A number of trained miners were engaged for subordinate posts, and the business began to look up. New sets of Russian gold-washing appli-

nances were put up, and gold washing began in earnest; but just then the war broke out, and a large part of the best workmen were called up to serve in the Army, and work at the mines again came practically to a standstill. In August and September there were at the mines more engineers and overseers than laborers, and the output of gold, instead of pounds, was merely an ounce a day or less. Generally the operations last year resulted in a loss, the output of gold for the year, instead of the expected 10 poods (5,760 ozs.), did not exceed 6 poods (3,456 ozs.). The labor at the mines consists of Russian peasants and Cossacks from the Russian frontier villages, and also some Chinese; but the company engage the latter reluctantly, as their work is half as productive as the work of Russian laborers. The native Mongols hire themselves out only for light work, the reason for which may be that digging the ground for gold is considered a sin according to the teachings of their lamas. The men are not on contract, but are engaged daily or by piecework. For a ten-hour working day the wages range from seventy copecks to two roubles. The pay is not very tempting for the men, and when some special work began on the Transbaikalian railway large numbers of men left the mines to work on the railway. Only the direst want and absolute lack of employment drives the frontier settlers to the gold mines, as, apart from the small pay, the conditions of living at the mines are far from attractive. The company provide no dwellings for the men, who are compelled to huddle together in butts or caves hurriedly put up by themselves. Food is dear and of inferior quality, and there is consequently frequent epidemics among the men. At the Iro mine there is a small hospital with three beds and a trained hospital attendant, but at the Tiridja mine the sick are left to their fate. After the arrival of the new general manager certain improvements were decided upon, including the better housing of the men, and workmen's barracks began to be erected at the expense of the company.

Personal.

E. L. BECK is with the Kondall M. Co. at Kendall, Mont.  
F. C. PAINE is with the Ruby Hill mines, Concordia, Wash.  
ALEX. WISE is assayer at the Chollar mine, Virginia City, Nev.  
R. S. DENNISON is assayer Homestake M. Co. at Lead, S. D.  
H. W. INGALLS is manager Copper King mine, near Mullan, Idaho.  
O. J. REYNOLDS is assayer East Pacific M. Co. at Winston, Mont.  
D. D. BUTLER is chemist Boulder Reduction Co. at Jamestown, Colo.  
H. P. GALLIGAN has charge dredger at Delta, Shoshone county, Idaho.  
WILLARD F. FRENCH is now with the Continental M. Co., Vulcan, Colorado.  
P. CASS has charge of the Odin mine in Thaynes canyon, near Park City, Utah.  
H. SIMINGTON is superintendent Grand View property, near Cherry Creek, Ariz.  
THOS. V. CONNOR is superintendent Wild Horse cyanide mill at Cripple Creek, Colo.  
B. H. DUNSHEE is assistant superintendent Amalgamated Copper Co. at Butte, Mont.  
H. D. MORSE is with the Boston & Montana Con. Copper & Silver M. Co. at Butte, Mont.  
E. P. KENNEDY is manager Susanville Commercial Co., at Susanville, Grant county, Or.  
WM. DUNNIGAN has left American Fork, Utah, to take charge of a property at Silver City, Utah.  
R. P. WHELOCK is assistant secretary and treasurer Enterprise M., R. & I. Co. at Kingman, Arizona.  
J. H. HAMMOND is examining the dredging interests of the tributaries of the Sacramento in California.  
CHAS. HANSON has been appointed foreman Witmer & Fuller mine, Placerville, El Dorado county, Cal.  
OTTO MEARS of Denver, Colo., has been inspecting the Golden Eagle Co.'s mine and mill at Winnemucca, Nev.  
J. H. FISK, Portland, Oregon, has been appointed consulting engineer Tenderfoot M. Co., Malheur county, Oregon.  
E. H. HARRINGTON has been elected superintendent Bunker Hill mine at Amador City, vice C. R. Downs, resigned.  
F. R. BALDWIN, superintendent Maitland properties, near Deadwood, S. D., has been visiting Chicago and the East.  
CHAS. BERGSTROM and O. OLESON, Butte, Montana, have left for Koperbik, Norway, to investigate mining properties.  
T. E. MARTIN of San Francisco has been appointed superintendent Mazeppa mine at Stent, Tuolumne county, Cal.  
C. E. BUTLER of Denver has been made manager of mines near Octave, Ariz., recently purchased by a Philadelphia company.  
H. W. BANGLE and M. L. GRIFFITHS are with the Sociedad Minera y Fundidora at Maconi, Cadereyta, Queretaro, Mexico.  
GEO. MORGAN, Salt Lake City, Utah, has been

elected president Sbeba G. & S. M. Co. at Unionville, Humboldt county, Nev.

H. D. SCRIBNER succeeds H. V. Croll as district manager the Allis-Chalmers Co., with offices at 623 Kobl Building, San Francisco, Cal.

M. L. REQUA has returned to San Francisco, Cal., from Ely, Nev., where he has been superintending the development of copper properties.

W. J. ADAMS, E. M., who was appointed by the court to examine the Copper King mine in Fresno county, Cal., has filed his report with the court.

E. H. DAVISON has gone from San Francisco, Cal., as manager U. S. & Mex. Syndicate, to operate extensive properties at Santa Lucia, Sinaloa, Mexico.

G. B. SHIPLEY has resigned as draughtsman in the San Francisco Union Iron Works mining department and taken a position with Allis-Chalmers Co., Chicago.

JOHN HARRIS goes to San Antonio, Nye county, Nev., about 20 miles north of Tonopah, to take charge of active work on three gold and copper properties there.

JOS. WATSON, Spokane, Wash., has been elected superintendent and manager Frisco-Standard M. Co.'s mine on Fish creek, 8 miles east of Boundary, Shoshone county, Idaho.

## Commercial Paragraphs.

H. C. BOSWORTH is now a partner in the new firm of Hoffman-Pintber y Bosworth, assay supplies, City of Mexico.

HENSHAW, BULKLEY & CO. of San Francisco, Cal., report the sale of a Kincaid mill to Brown Bros. of Prescott, Ariz.

THE new warehouses of The S. H. Supply Co., Denver, Colo., fronts 200 feet on Lawrence street and 125 feet on Eighteenth street, and are occupied entirely by this company with a stock of machinery and storing of supplies, together with the offices of the company. Besides this building, the company has three warehouses, a tank factory, trackage and several acres of yard room at Thirty-first and U. P. R. R. tracks. The company reports progress from sales in 1898 of \$12,000 to over a million dollars in 1904.

BLAISDELL CO. of Los Angeles, Cal., patentees and manufacturers of sand vat distributors, excavators and tailings stacking machinery for cyanide plants, has a contract with the Black Mountain M. Co., Magdalena, Sonora, Mexico, for a complete installation of their system. The Black Mountain M. Co. is developing the old Cerro Prieto mine and other properties in that vicinity and is erecting a 120-stamp (1250 pounds) mill, with a cyanide plant, having vats 40 feet in diameter by 8 feet deep, to filter. The Blaisdell system is intended to have a capacity of 100 tons of sand per hour.

THE A. S. Cameron Steam Pump Works, foot East Twenty-third St., New York, report their February business encouraging and the volume of orders increasing. Among their recent sales they report pumps of different sizes and types, mostly mine pumps, for the Union Iron Works, San Francisco, Cal.; three of large capacity for use at Battery Park, New York City, supplied to the Barrett Mfg. Co.; several pumps, with removable hushings for pumping tar, for the D. L. & W. R. R., in New Jersey; a large light-service pump for the Western Tube Co.; three general-service pumps of different sizes for McClung & Co., Knoxville, Tenn.; three general-service pumps for the Oil Well Supply Co., Bradford, Pa.; boiler feeders and general service pumps for Griffiths & Nathaniels, Poultny, Vt.; Granville Die & Machine Works, Granville, N. Y.; New Suddy Coal Co., Tennessee; H. Channon & Co., Chicago, Ill.; Hullock Milling Co., Hullock, Md.; Dept. of Water Supply, Alexandria, Ind. Their foreign shipments are quite active. Fourteen light pumps were ordered from London, Eng., for delivery to the west coast of Africa; six pumps direct to Auckland, N. Z., and special sinking and station pumps to Ste. Anonyme des Mines d'Or de Territo, Brazil, and Cia. Mina. de Penolis, Mapimi, Durango, Mexico.

## Books Received.

"Preliminary Report on the Ohio Co-operative Topographic Survey," by C. E. Sherman, gives a resume of geological work done in Ohio during 1902-1903.

The United States Geological Survey Bulletin, No. 244, "Contributions to Devonian Paleontology in 1903," by H. S. Williams and E. M. Kindle, classifies and discusses evidence found in Kentucky, Virginia and West Virginia.

At a small mine the superintendent who is expected to direct all the details of work around the mine will find some valuable information in "How to Mix Paints," by C. Godfrey. It gives clear directions that will save both time and materials on any job of painting about the mine. It is published by the Industrial Pub. Co., 16 Thomas St., New York City, for 50 cents, and will be sent postpaid by the MINING & SCIENTIFIC PRESS upon receipt of price.

"A Handbook of Construction for Superintendents of Construction, Architects, Builders and Building Inspectors," by H. Ricbey, contains valuable information on materials of construction and their utilization. The whole is presented in a logical manner, and, while condensed to the limits of a handbook, yet it presents all the essential details. It is published by John Wiley & Sons, 43 East Nineteenth street, New York City, for \$4,

and will be sent postpaid by the MINING AND SCIENTIFIC PRESS upon receipt of price.

The bureau of the census of the United States Department of Commerce and Labor has issued its report on "Mines and Quarries, 1902," prepared under the supervision of W. M. Steuart. This great volume is filled with statistical information regarding the mineral production of the United States for 1902. The book deals with figures on amount and value of minerals produced, localities, number of men engaged in the industry, wages received and power employed. Most of the figures are presented tabularly and diagrammatically. On the whole, the work shows great care in preparation and the facts seem to be trustworthy. Little is published, except the statistics as to labor, that has not already appeared in other government reports. It is to be regretted that statistics for the year 1902 cannot be made public before 1905, for in this time many changes have been made in this industry and the facts here presented cannot be taken as a criterion of present conditions. This criticism has been made of the work of the United States Geological Survey, but this census report appears more than a year after the Survey's report for the same year.

## Trade Treatises.

The Wellman-Seaver-Morgan Co. of Cleveland, Ohio, describe the advantages of the Johnson patent arch plate in an illustrated leaflet.

No. 32 catalogue from Woodin & Little, 312-314 Market street, San Francisco, Cal., describes that firm's line of gasoline engines, pumps, windmills and tanks.

## Latest Market Reports.

SAN FRANCISCO, March 17, 1905.

### METALS.

SILVER.—Per oz., Troy: London, 26½d (standard ounce, 925 fine); New York, har silver, 58½c, refined (1000 fine); San Francisco, 58½c; Mexican dollars, 48½c, San Francisco; 45c, New York.

COPPER.—New York: Standard, \$15.50; Lake, 1 to 3 casks, \$15.37½; Electrolytic, 1 to 3 casks, \$15.37½; Casting, 1 to 3 casks, \$15.25. San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18½c. London: £68 11s 3d spot per ton.

LEAD.—New York, \$4.60; Salt Lake City, \$3.50; St. Louis, \$4.12½; San Francisco, \$3.70, carload lots; 4½c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5½c; pig, \$4.85. London: £12 5s 3½d long ton.

SPELTER.—New York, \$6.25; St. Louis, \$6.15; London, £23 17s 3½d; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

TIN.—New York, pig, \$29.37½; 29.75; San Francisco, ton lots, 30c; 500 lbs., 30½c; 200 lbs., 30½c; less, 31c; bar tin, 32½c. London, £134 17s 6d.

PLATINUM.—San Francisco, crude, \$18.50 per oz.; New York, ingot, \$19.50 per Troy oz. Platinum ware, 75¢ to 82¢ per gram.

QUICKSILVER.—New York, \$40.00 to \$41.00 large lots; London, £7 12s 6d; San Francisco, local, \$38.00 per flask of 75 lbs.; Denver, \$45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c. SOLDER.—Half-and-half, 100-lb lots, 19.75c; San Francisco, Plumbers', 100-lb lots, 16.50c.

ZINC.—Metallic, chemically pure, 50c; dust, 40c; 10c; sulphate, 40c.

NICKEL.—New York, 55¢ to 60¢ per lb.; ton lots, 40¢ to 47¢.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31¢ to 34¢.

ALUMINUM.—No. 1, 99%, small lots, 37c per lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburgh. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburgh.

### STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$16.35 to \$16.85; gray forge, \$16.65; San Francisco, bar, 3c per lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburgh, \$23.00 to \$27.00; open hearth billets, \$23.00 to \$27.00; San Francisco, bar, 7c to 12c per lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, ¾c per lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ¾c per lb. above keg price.

Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LUMBER.—(Retail): Pine, ordinary sizes, \$24.00 to \$5.00; extra sizes higher; redwood, \$28.00 to \$30.00; latb, 4 eet, \$4.50 to \$5.00; pickets, \$21.00; shingles, \$2.50 for No. 1 and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00 to \$35.00.

NAILS.—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.55; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d, Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4d and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

LIME.—Santa Cruz, \$1.25 country, \$1.25 city per bbl.

CEMENT.—Imported, \$2.15 to \$2.65 per bbl.; California, carload lots, \$2.10 f. o. b. at works; small lots, \$2.40 per bbl. in sacks, 4 sacks to bbl., 10c for each sack returned.

### GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 7½c; Hallett's, 7½c; San Francisco, 1000-lb. lots, 9c; 300 to 500-lb. 9½c; 100-lb. lots, 10½c.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lot, Eastern and foreign: Wallend, \$7.50; Brymbo, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8.00; Cumherland, \$13.00; Cannel, \$8.50; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13.00 in sacks; Sunnyside, \$8.50, long ton.

POWDER.—F. o. h. San Francisco: No. 1, 70% nitro-

glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1\*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1\*\* 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg.

CAPS.—3x, \$5.50 to \$6 per 1000; 4x, \$6.50 to \$7; 5x, \$8 to \$8.50; Lion, \$9 to \$9.50, in lots not less than 1000.

FUSE.—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c per set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23 to 24c per lb.; carloads, 23 to 23½c; in tins, 30c; soda ash, \$2.00 per 100 lbs.; byosulphate of soda, 3 to 3½c per lb.; caustic soda, in drums, 3 to 3½c per lb.; Cal. s. soda, bbls., \$1.10 to \$1.20 per 100 lbs.; sks., 90c to \$1.00; chlorate of potash, 12 to 13c; nitrate of potash, 6½ to 7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½ to 2¾c; powdered sulphur, 2½ to 2¾c; flour sulphur, French, 2½ to 2¾c; alum, \$2.00 to 2.25; California refined, 1½ to 2c; sulphide of iron, 8c per lb.; copper sulphate, 5½ to 5¾c; chloride of lime, spot, \$2.50 to 2.75; sulphuric acid, in carboys, 66% B, 1½ to 2c per lb.; nitric acid, carboys, 8c per lb.

OILS.—Linseed, boiled, bbl., 60c; cs., 65c; raw, bbl., 58c; cs., 63c; Lucol oil, boiled, bbl., 51c; cs., 56c; raw, bbl., 49c; cs., 54c. Kerosene—Pearl, per gal., 19c; As; tral, 19c; Star, 19c; Extra Star, 22c; Eocene, 21c, Elaine, 25c; Water White, in bulk, 12½c; Mineral Seall iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Minera; Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 16c, do., cs., 22½c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naptha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; 78c; Sperm, crude, 63 to 68c; Natural White, 63c; Bleached, do., 57c; Whale Oil, cs., 52 to 57c.

BORAX.—Concentrated, 6 to 7c per lb.; powdered, 8 to 10c; fused, 20 to 25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5 to 6c per lb.; No. 1, 4 to 5c.

LITHARGE.—Pure, in 25-lb. bags, 8 to 9c per lb.

MOLYBDENUM.—Best, \$2.75 per lb.

CHROMIUM.—90% and over, per lb., 80c.

PHOSPHORUS.—American, per lb., 70c.

SODIUM.—Metal, per lb., 50c.

BISMUTH.—Subnitrate, per lb., \$2.10.

URANIUM.—Oxide, per lb., \$3.50.

MERCURY.—Bicarbonate, per lb., 77c.

TUNGSTEN.—Best, per lb., \$1.25.

SILVER.—Chloride, per oz., 90c to \$1.00; nitrate, 55c.

RED LEAD.—500 lbs. and over at one purchase, per lb., 7c; less than 500 lbs., 7½c.

MANGANESE.—Per lb., \$2.75.

MAGNESIUM.—Pure, N. Y., \$1.60.

FIRE BRICK.—Domestic, carloads per 1000, f. o. b., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skewback, \$30.00; circle, \$32.00.

FIRE CLAY.—Domestic, per ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, \$3.50.

## New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING MARCH 7, 1905.

784,202.—TELEPHONES—Andriano & Herbstreit, San Francisco.  
784,203.—TEAM DRIVER—Arnold & Kress, San Francisco.  
784,204.—METAL CUTTER—C. C. Atkins, Los Angeles, Cal.  
784,475.—AWNINGS—T. J. Daniels, San Francisco.  
784,252.—PULLEYS—Dethlefsen & Grah, San Francisco.  
784,389.—VALVE GEAR—W. F. Diden, Santa Monica, Cal.  
784,039.—SAD IRON—M. E. Fallon, Spokane Wash.  
784,257.—TRAIN GUIDE—P. Flanagan, San Francisco.  
784,258.—GARMENT FASTENER—F. Franz, San Francisco.  
784,153.—HAME HOOK—T. G. Gordon, Madras, Cal.  
784,211.—BLOTTING PAD—C. J. Hasman, San Francisco.  
784,213.—TRACE HOLDER—C. Heilrath, Sacramento, Cal.  
784,214.—TRACE HOLDER—C. Heilrath, Sacramento, Cal.  
784,490.—SHADE BRACKET—C. Heilrath, Sacramento, Cal.  
784,405.—WASHING MACHINE—P. P. Klef, Oakland, Cal.  
784,219.—BOTTLE FILLER—F. J. Lewis, Sacramento, Cal.  
784,058.—CLOBE—Manson & Conick, San Francisco.  
784,152.—SPIRIT LEVEL—H. N. Northolt, San Francisco.  
784,120.—CYANIDE TREATMENT—E. L. Oliver, Oakland, Cal.  
784,421.—STRING CUTTER—E. H. Painter, Alpha, Wash.  
784,348.—SAWING MACHINE—B. J. Pve, Astoria, Or.  
784,124.—HARDENING IRON—F. L. Ramon, San Francisco.  
784,179.—ROTARY ENGINE—C. P. R. Roy, Stirling City, Cal.  
784,227.—SEARCHLIGHT—B. C. Riblet, Spokane, Wash.  
784,154.—OIL BURNER—L. B. Rosen, Los Angeles, Cal.  
784,230.—HAY RAKE—S. Roth, Winnemucca, Nev.  
784,505.—INJECTOR—A. C. Rush, Los Angeles, Cal.  
784,436.—OIL FEEDER SYSTEM—R. F. Schroeder, Sacramento, Cal.  
784,126.—OIL BURNER—J. Schurs, Los Angeles, Cal.  
784,184.—SAWING MACHINE—G. F. Sehrl, Alsea, Or.  
784,438.—CURLING IRON—G. F. Shields, Kern, Cal.  
784,076.—CUP HOLDER—J. W. Shute, Iternia, Cal.  
784,428.—OIL BURNER—Smith & Dietz, Tucson, Ariz.  
784,445.—PIPE CUTTER—F. M. Sylvester, Hamilton, Wash.  
784,240.—WOOL WASHER—J. H. Tillenbush, Stockton, Wash.  
784,083.—BRIQUET PRESS—J. Treadwell, San Francisco.  
784,452.—WIRE STRETCHER—F. Verhoeven, Forest Grove, Cal.  
784,527.—PEELING FRUIT—C. J. Vernon, Fresno, Cal.  
784,455.—FEED RACK—G. R. Warren, Spokane, Wash.  
784,018.—TELEPHONE—W. D. Watkins, San Jose, Cal.  
784,199.—BOTTLE—O. Yates, Portland, Or.

## Notices of Recent Patents.

SM

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

GARMENT FASTENER.—No. 784,258. March 7, 1905. F. Franz, San Francisco, Cal. This invention is especially designed for securing parts of garments and attachments thereto. It consists in fitting an independent elastic ring of peculiar construction to encircle a stem or shank, so that when said stem or shank is introduced into a socket of a companion part the edges of said part will clasp the ring while the latter is freely turnable about the stem, and such devices may be used for connection of parts of clothing or other equivalent purposes.

STEAM DRYING DEVICE.—No. 784,293. March 7, 1905. H. V. Arnold and A. H. Kress, San Francisco, Cal. This invention relates to a device especially designed to separate steam from water with which it is associated in steam boilers and the like and to produce a substantially dry steam for use. It consists, in part, of a ring fixed to a steam discharge pipe, a plurality of rings and intermediate screens at the inlet to said pipe, a pan underlying the lowermost ring, means for drawing the pan from the inlet ring and bolts passing through the pan and the rings and screwed into engagement with the first named ring, and other details of construction.

## Cyaniding in Mexico.

Some of the largest and most successfully operated cyanide plants in the Western Hemisphere are in Mexico. The accompanying illustration is that at the Peregrino (Pilgrim) mine, 8 miles west of the city of Guanajuato. The ore carries both gold and silver, and is what would generally be considered low grade, though ore of high grade is also found in it. The mine has extensive development, and was worked years ago by Mexican owners, but, failing to yield a profit by the native methods in vogue at that time, was closed down and remained idle for years. In 1903 W. H. McCord of Nevada City, Cal., went to Mexico on mining business and, being in Guanajuato, heard of the Peregrino mine, investigated it, and, arranging with the owners a price and what he considered reasonable terms, interested American capital and reopened the old mine. Kinkead mills and a complete cyanide plant were

put in, the latter being the subject of the illustration, from a photograph taken for the Redwood Manufacturers' Co. of San Francisco, Cal., who furnished the equipment. It is arranged to work, as far as possible, on the gravity plan, and under existing conditions of climate, price of labor, and character of material to be treated, has been called by some who have seen it a model plant. It differs in some respects from the ideal plant in the United States, but the

low cost of labor evidently justified some of the unusual features of construction and method of operating.

It is reported that this property was recently sold to a new company for \$480,000, and the new owners

have taken possession. There is a large amount of ore in sight, which, with improved American methods, should yield a good profit. There are many mines in Mexico lying idle which, with proper equip-

ment and operation, could be made dividend payers, but those contemplating investment in these properties should "take nothing for granted," for the Mexicans themselves have reputations as good miners.

## The Latest Mining Rush.

The first of a series of privations and hardships suffered by stampedeers into southern Nevada from California is reported. It is stated that the trails leading to Goldfield via Death Valley from various points along the railroad in southern California is lined with all sorts of outfits bound for the new gold mines. Water is scarce, and only obtainable at a few springs and wells situated at long distances apart. It costs ten cents at roadside houses to water stock and a dollar a meal for travelers. Hay is sold in small amounts at prices ranging from \$30 to \$60 per ton. The desert roads—never good at best—are now in deplorable condition, owing to extensive washouts. The roads are lined with dead horses and mules, and the unfortunate losers of these animals have either made arrangements to go forward with others or have turned disgustedly homeward, hastening to try again. In some instances the more foolhardy are attempting to walk, taking chances on getting to the new El Dorado. It is no new thing to meet with hardship and discomfort on a mining stampede in a country well timbered and watered, and where life is endurable, if food can be obtained at all, but a stampede across a desert amid rugged and verdureless hills, through deep sands or floundering in the clayey muck of a desert sink, is quite a different matter—and those who have not had experience on the desert undertake a risky task when they attempt to cross the desert from Mojave or Daggett, or any intermediate point in California to the Goldfield region of Nevada.

## Value of a Mine Report.

There is a great range in the value placed on a mine report made by different men and there is as great a difference in the actual value of reports made on the same property by different men. Mine reports are made for various purposes, not infrequently for the purpose of the owner, who wishes to obtain the facts, having a bearing on the workings of his mine and the treatment of the ores, or as a means of ascertaining the actual value of the property, present and prospective, but more often the report is intended as a basis of fixing a selling price on the property or for the purpose of raising money to equip and further develop it. In the latter case the opinion of the man whose report will sell stock is the one that is wanted. In the former case this is a consideration of less importance. Some months since a mine promoter employed an engineer to make an examination of a mine which had been extensively equipped and developed, and which had produced considerable money, but in a spasmodic manner. The engineer made a careful examination, accompanied the greater part of the time by the promoter. When the examination had been completed a verbal report was made to the effect that the mine did not possess the elements of success. The promoter acknowledged that the situation looked discouraging, and said he understood it fully; that the verbal report would be sufficient. The engineer was paid, and, so far as he was concerned, the matter was dropped. A few days later another man of some reputation appeared at the mine, and the promoter explained to his engineer that he had come in a consulting capacity. A few days later the further information was volunteered that the second engineer would make a written report, which he did. Many thousands of dollars was raised with its aid, a larger mill built and a new period of activity inaugurated, but it was the last spasmodic effort. The mine failed to meet the promise of the report and was closed down and remains so still. Comment on an instance of this kind is unnecessary. The engineer whose reports become of greatest value is he whose opinions as expressed in his reports are verified by actual results, whether these be good or bad, and no engineer who seeks permanent good standing can afford to allow friendship or any other consideration to stand in the way of making his reports in absolute accordance with the facts.

## Broken Hill Report.

The half-yearly report to December 1, 1904, of the Broken Hill Proprietary Co. of Broken Hill, N. S. W., recently issued, shows that during the period covered by the report 324,535 tons of ore were mined, and that 79,158 cubic yards, or about 160,000 tons, of waste were broken in the open cuts to fill stopes below. A great deal of attention has been given the past two years at Broken Hill to the concentration problem. At the concentration works over 300,000 tons of sulphides were treated, and the cost of concentration per ton reduced, it is said, owing to the large quantity handled, and a closer saving of lead and silver effected by exercise of greater care. For years the zinc ores occurring so abundantly in the Broken Hill mines had no market, and particular attention was given this problem during the past two years. Several different schemes for the separation of zinc sulphide from the galena and iron have been tried, most prominent among them being the salt-cake process, an invention of G. D. Del Prat, the general manager, and magnetic separation. The report states that as particularly favorable results were obtained by the salt-cake process, magnetic separation was temporarily suspended. Nearly 28,000 tons of mill tailings were treated by the salt-cake method, resulting in 8104 tons of high-grade zinc concentrates. The tailings were conveyed to the open cut and sent through chutes into the stopes below. This is an innovation and is doubtless permissible in a dry mine. What the result of the adoption of this method would be below the water level is speculative, but it is reasonable to assume that it would be found most difficult to restrain the sands, which, when saturated with water, would run badly and probably fill the lowest workings. This company about a year ago put in an acid making plant, and during the half year under discussion enlarged the plant. With one

chamber 400 tons of sulphuric acid was produced. This acid—a by-product, as it were—is employed in the Del Prat salt-cake process, and as the raw materials are largely produced by the mine, the process is cheaper there than other methods requiring power in their operation. The Broken Hill mines are situated in a semi-desert country, where the rainfall is light, and usually all falls within a short period, in the form of heavy showers, sometimes approaching the character of cloudbursts. The source of supplies is distant and everything about the mines is taken advantage of, and as a result costs are reduced far below what they were in former years, when the ore was higher in grade, nearer the surface and easily treated by smelting.

## A New Inland Sea.

The Colorado river is reported overflowing its banks below Yuma, and a great flood is pouring into Salton basin in the Colorado desert, in San Diego county, Cal. The fear is entertained by many that the basin may again become a great interior lake, as it once was. The Salton basin is below the level of the sea, the old shore line being plainly visible for many miles around the basin. The area included within that portion lying below the normal level of the Colorado river at the breach which that stream has made in its west bank is about 4000 square miles, and owing to the tremendous absorption of the desert sands, and the high evaporation factor, if the river were to pour its entire flood into the basin it would require twelve to fifteen years to fill it to the old shore line level. What effect such an event would have on the climate is speculative, but much railroad property would be submerged and many miles of track would have to be torn up or abandoned, and the line built on higher ground, but there is little fear of such a result unless the work of the river is aided artificially to accomplish this. The Colorado river is rather higher than usual at this time of the year, and it is said that the breach was made by irrigators who opened their main ditch directly to the river. Should the river maintain its present high stage—and this is likely to be increased by melting snows in the Rocky Mountain region—the river may do much damage to the salt works and railroad property in the lowest part of the basin at Salton. It is now nearly fourteen years since the Colorado river overflowed into the basin through what is known as Hardy's Colorado or New river. The river is said to be higher now than at that time. Although great damage would result should the basin again become a lake, it would undoubtedly be of benefit to the mining industry in that part of California, as there is a great scarcity of water there and the lake would afford both abundant water and cheap transportation facilities.

THE Keswick smelters of the Mountain Copper Company, in Shasta county, Cal., will be blown out as a result of the recent decision finding for the Government against the copper company for damages to trees and other vegetation in the neighborhood of Keswick. The company has given notice to the several mines which have supplied the smelters with siliceous ores for flux that no more ores will be received. An interesting phase of the situation about Keswick lies in the fact that many of the trees in the damaged district are showing renewed signs of life, and reports from Happy Valley, one of the affected districts, are that the fruit trees and grass are flourishing this year, and even the pine trees are again bearing cones. This is thought to be due to the fact that the practice of heap-roasting has been discontinued at the smelters for several years past, and also partly to the fact that the rainfall has been more abundant this year than usual.

THE application of electricity to mine drainage through the medium of electrically driven pumps is becoming recognized as possessing some advantages over other methods in certain cases. What the limitations of electrically driven pumps, as applied to mining uses, will be, remains to be determined. An installation in Germany consisting of two electrically driven pumps raises 1500 gallons per minute a height of 1700 feet. This is said to be accomplished with a combined efficiency of 58%. The efficiency of the pump alone is stated to be 77%.

## CONCENTRATES.

THE chloride of gold in nature is a myth, no authenticated instance being cited by authorities.

CHLORINATION of auriferous sulphides at some California mines has been discontinued for shipment to smelters.

IN putting up a long raise it is always advisable to meet it by sinking from the level above. It will in most cases prove the more economical plan.

THE largest mass of gold discovered in California is said to have weighed 2340 ounces. It was taken from the Bonanza mine at Sonora, in Tuolumne county.

THE bonanzas of the Comstock Lode at Virginia City, Nev., appear to have been formed at a later period than the immense masses of quartz in which they occur.

ZINC BLENDE is often rich in gold or silver, or both. The zinc ores of Missouri and the other fields of the Mississippi valley contain little, if any, silver or gold.

IT has been asserted that chlorides and silicates of gold exist in nature, but so far as known to "Concentrates" there are no authoritative records of such occurrence.

THE pay shoot of the Smuggler-Union mine, near Telluride, Colo., is described as being over 5000 feet in length and has proved profitable throughout that distance.

TANTALUM is an element and a metal. Tantalite is a tantalite of iron and manganese having the formula  $\text{FeMnTa}_2\text{O}_6$  and is sometimes accompanied by cupric oxide and lime.

IT was first proposed to treat copper mattes by the Bessemer process as early as 1866 in Germany, but no progress was made in the practical application of the idea at that time.

THERE is no law or apparent relation between the strike and dip of a vein and its value, though there is often a marked difference between veins in the same district having a different strike and dip.

THE silver in the mine at Running Water, near Lusk, Wyo., is mostly native and occurs in a stratum of Cambrian quartzite lying on Archean schist. The quartzite is stained with thin incrustation of copper carbonate.

DRIED mill tailings may be used for filling in a dry mine; but their use is not advised in a wet mine, for the wet sand is sure in time to run and give much trouble at points lower than the stopes which have been filled in this manner.

AN extensive description of the Silver Islet mine, in Lake Superior, will be found in the Transactions American Institute Mining Engineers, Vol. VIII (1879), page 134 et seq., which may be found in almost any public library in a large city.

SAMPLES of selenite (a transparent variety of gypsum) are frequently sent for identification in the belief that the mineral is mica. A very simple test is to lay a piece of the mineral on a hot stove. If it is selenite, it will soon turn white and become opaque.

CONCENTRATES which are to be treated after roasting by the chlorination process should be as clean as possible, particularly where the gangue contains considerable lime or magnesia, as these substances unite readily with chlorine and make the process more expensive.

THE present rate of coal consumption in the United States is 1,000,000 tons daily. While it is probable that even this vast amount will be largely increased, it is not believed that there need be any serious thought given to the probable diminution of the supply during the present century.

THE lowest grade of copper ore which may be successfully smelted depends much on surrounding economic conditions—availability of fluxes, cost of fuel and transportation and on the cost of labor. Copper ores have been smelted in British Columbia in the Boundary district, it is reported, for less than \$3.50 per ton.

GALENA and CARBONATE OF LEAD (cerussite) are the principal sources of the lead of commerce. Wulfenite, anglesite, pyromorphite and the several antimonial lead compounds are relatively unimportant. Metallic native lead is reported from a few localities, but native zinc, so far as known to "Concentrates," is unknown.

THERE is no particular device on the market, so far as known to "Concentrates," designed to separate gold from black sands of ocean beach or river. The numerous types of concentrators may effect a partial separation, and inclined tables covered with hurlap are sometimes used for this purpose. Several years ago an amalgamator was made in San Francisco, Cal., which was

essentially a slightly inclined revolving cylinder, having diaphragms or wings, arranged longitudinally within it. The gold-bearing sand was introduced at the upper end, and the sand discharged at the lower end, the greater part of the gold remaining attached to the amalgamated plates within the machine.

SALT WATER and water containing other minerals in solutions have been successfully used in amalgamation and to some extent in cyanidation, particularly the latter. As far as known to "Concentrates," neither sodium chloride nor sodium carbonate in solution in battery water have a bad effect on amalgamation, though waters containing arsenic and free sulphuric acid are known to be detrimental to close amalgamation.

WHEN the only available water for steam making contains sodium chloride or sodium carbonate or other mineral salts which interfere with steam making, the best way to overcome the difficulty is to condense the salt water and use only distilled product in the boiler. This was done extensively in West Australia prior to the completion of the great Kalgoorlie pumping system, as salt water was the only kind available in that region.

PUMPS of various design have been employed to "suck up" gold-bearing material from deposits situated below the water level, but the wear on reciprocating pumps employed for this purpose is heavy. More recently pumps and dredgers operating on material of this kind are of the centrifugal type. The parts subjected to the greatest amount of abrasion are made of very hard steel and are readily replaced by new parts when worn.

DIABASE is frequently found associated with gold-bearing veins, but rich veins are accompanied by other intrusive rocks as well as diabase, and within them. Ore shoots are known to occur with nearly every kind of intrusive rock known, from the most acid granite and felsite to basalt. The association with the latter is of comparatively rare occurrence, the most noted instances of this kind being in the Cripple Creek district of Colorado.

EXHAUST STEAM conducted through good-sized galvanized iron pipes 2 feet or more in diameter and placed beneath the battery plates or in front of them will warm the mill sufficiently. A coil of pipe in the mill tank, through which a small amount of live steam is passed, or even exhaust steam, will warm the battery water sufficiently in the coldest climate. Battery water for the best work should be between 50° and 55° F. It is not necessary or advisable to have it even lukewarm.

COPPER SULPHIDE ORES may in many cases be changed to sulphate in an inexpensive manner by spreading them out in beds and leaching and re-leaching them with a saturated solution of brine containing ferrous sulphate, which latter is a by-product of the precipitation of the copper. This process facilitates the decomposition of the sulphides, with the formation of sulphates, but it is a very slow process, often requiring several years, and even then the extraction of the copper is incomplete.

WHERE placer gold is found in gulches or on flats, where no gold-bearing veins or pockets can be found, the natural conclusion is that the gold must have been derived from some distant source, even though the topography of the country about may appear to controvert the correctness of this theory. Gold is not infrequently found in gravel on hilltops where it was deposited before the hill was created by the erosion of the surrounding rocks.

THERE is some difference of opinion as to the proper succession of the drop of stamps. The drop most commonly used in the United States is 1, 4, 2, 5, 3. In some districts of the United States and Australia the order of drop is 1, 5, 2, 4, 3. This order is said to scour the chuckblock plate and to cause more rapid wear of the screen. In some mills 3 of the 5 stamps of a battery are allowed to fall almost simultaneously, but it is not recognized as the best practice.

THE black sands in river beds, ancient and recent, are mostly iron. Some of the sand is magnetic and some is not. It is probable that the magnetic sand is due to the disintegration of greenstones and lavas in which magnetite is more or less abundant. Titanic iron is also partly from lavas and partly in some instances from granitic rocks. The remainder of the iron sand is in most instances limonite resulting from the oxidation of pyrite. The latter is often gold bearing.

THERE are a number of substances associated with gold in ores which render the gold difficult of amalgamation, for the reason that these substances coat the little particles of gold with a film which prevents a contact with quicksilver. Among these substances are talc, graphite, molybdenite and manganese oxide. The difficulty in most cases is mechanical and not chemical. When it occurs concentration should be tried and the floating scum of the undesirable minerals conducted off from a tank and settled under water.

WHERE the rocks through which a shaft is being sunk are hard and firm, it may be permissible to put in only sufficient timber in the form of plates or stulls to

carry the ladder ways, pipes and guides, or track, but if the shaft is intended as the main working shaft, through which a large amount of ore is to be hoisted, the opening should be substantially timbered throughout with the usual shaft sets. In the case of firm solid ground, as described, these sets may be placed 6 or even 7 feet from center to center instead of 5 feet, as usual.

THE grade of gold-bearing gravel which may be dredged with profit depends upon the cost of working, and this varies with the conditions. Some gravels may be dredged much more cheaply than others. The character of bedrock is also often an important factor. The prospecting drill may often recover from hard, rough bedrock, gold which can not be readily brought up by the dredger. The ideal conditions are a bank not over 60 feet deep, the gravel easily moved, and containing few boulders of large size, with a soft bedrock which may readily be cut by the dredger bucket, and brought to the surface.

THE exact temperature at which gold ceases to be attacked by chlorine and the rate of volatilization of chloride of gold are of importance in connection with the roasting of auriferous sulphides in the presence of salt. Rose in his "Metallurgy of Gold" claims that gold unites with chlorine if placed in the gas at atmospheric pressure at all temperatures up to a white heat, but the subsequent decomposition of the chlorine is rapid above 300°. The absorption of chlorine by gold with the formation of chlorides at first increases in rapidity as the temperature rises, and reaches its maximum at about 225° C.

MERCURIC CHLORIDE is employed in amalgamation in several patented processes. In what was known as the Designolle process a charge of 600 pounds of ore was placed in an iron barrel or pan, with the barrel or pan about one-half filled with water. To this was added one gallon of a solution containing 1.7% of mercuric chloride, one gallon of hydrochloric acid, and two gallons of salt, provided the ore did not exceed \$15 gold per ton. It was calculated to introduce to the charge ten parts of mercury to one of gold. The barrel or pan was rotated for about twenty minutes and then discharged into a settler, and the amalgam caught on copper plates.

COMPRESSED-AIR MOTORS are successfully employed in mine haulage at a number of places. At the Red Point mine, Placer county, Cal., the power is derived from the water flowing from the mine, which is collected and carried to a water wheel, which it operates under 600-foot head. The air pressure in the motor receiver, when freshly charged, is 700 pounds per square inch. This is sufficient to supply power to the motor to take the train into the mine on an upgrade. On coming out loaded, the train is controlled by brakes of the ordinary type, operated by hand. Originally, these brakes were controlled by compressed air, but it required about as much air to brake a train out as it did to haul one in by means of the motor, and the practice was discontinued.

THE expense of taking out a patent to a mining claim can not be arbitrarily stated, for the reason that the cost of several of the important items is not fixed by law. Generally speaking, \$300 should cover all the expense, including the cost of the land in one full quartz claim of twenty acres and about \$250 in the case of a single 20-acre placer claim. The fee of the United States Land Office is \$10, and in the office of the Surveyor General there is a charge of \$35 for stationery and office work and \$40 if the claim be placer. An abstract of title must be furnished, and the cost of this may vary greatly, from \$10 to over \$100, depending on circumstances. The cost of publication is not fixed, nor are the attorneys' fees, and these may vary greatly. The United States Land Office in California has given the following figures as approximating the cost of patenting a quartz claim: Payment of the land, twenty acres at \$5 per acre, \$100; Surveyor General—Deposit, \$35; publication notice, \$25; affidavits, etc., \$5; deputy surveyor, \$40; land office fee, \$10; total, \$220. To this must be added attorney fees, publication notice, abstract of title and other incidental expenses.

TO QUICKLY HANDLE a steam pump in a shaft, the steam and discharge pipes should be provided with slip joints at least 20 feet in length, and the exhaust should be conducted into the sump. By means of the slip joint the pump may be pulled up at least three sets and protected by a bulkhead when ready to blast. It is also desirable to connect the column pipe by flange joints instead of the ordinary couplings. Rubber hose soon vulcanizes and is unsatisfactory where the steam must be turned off from time to time, as must be the case when the pump is stopped to blast or from any other cause. Where a station has been cut, or a tank provided at one side of a shaft, the water coming down the shaft may be caught on the timbers by means of narrow slats tacked on the upper face of the timbers close to the inner edge, and these, with the aid of small clay dams, will turn the water inward toward the walls, where it may be caught up and conducted to the tank and either sent out by skip or pumped to the surface by a stationary pump. By catching up the water at various levels in the shaft, the sinking pump in the bottom is relieved of much of its duty and can be utilized to better advantage.

### The Mines of Tonopah, Nev.

The recent unusual activity in southern Nevada dates back to the discovery of the Mizpah mine by J. L. Butler in May, 1900. The locations were perfected the following fall. After being worked by leasers—there being thirteen blocks—this claim, to-

vein outcrop, prospecting about Tonopah, though not lacking in vigor, was necessarily uncertain. The ore-bearing formation (andesite) was found overlaid throughout the greater part of the district by later flows of volcanic material, the only exposures of vein apex being in a comparatively limited space which had been exposed by erosion. Still so active and de-

which are scattered about the landscape without system or regularity. This is evident by a glance at the accompanying illustration of the town of Tonopah and surrounding hills. The several hills and ridges are separated by rolling or sloping country covered with coarse sand and supporting a scattering growth of sagebrush. Not a tree of any de-

Styles of Architecture Found at Tonopah, Nevada.

gether with the several other claims of the group, passed by purchase to the Tonopah Mining Company, Jan. 1, 1902. During the period immediately following the recognition of the value of Butler's discovery, with which he was not much impressed himself at first, hundreds of locations were made, and thousands of feet of shaft and other underground development has been made. Owing to the limited exposures of

terminated was the work of exploration that several mines have, in the course of their development, struck veins of rich ore.

The region in which Tonopah is situated may readily be recognized by an experienced geologist or prospector as of volcanic origin, by its topography. It consists of a series of elevated mesas which have been cut by erosion into detached or connected hills,

scription in sight. The town is at an altitude of 6000 feet and the highest elevation in the district is Mount Butler, 7160 feet.

There are no true sedimentary rocks in the district, though limestones and older eruptive rocks—granite and diorite—are known both north and south of Tonopah. In the immediate vicinity of the town all the rocks are of volcanic origin, either massive

eruptions or tuffs. The oldest rock outcropping in the district, although much altered, still retains sufficient of its characteristics to make its identification possible. It is hornblende andesite, an abundant Tertiary eruptive in the Great Basin region. This formation was subjected to much movement and fracturing, together with the crushing of zones of greater or less width along the lines of fracture, and in these zones the mineralization took place. In appearance the ore resembles that of the Comstock Lode, at Virginia City, Nev.

Later eruptions of andesite followed the fracturing of the andesites of the first period, this later andesite being more basic than the former, and may be termed augite andesite.

Still later eruptions of rhyolite, a quartz-bearing trachyte, and of dacite, quartz-bearing andesite, followed the later andesite eruptions. No mineral veins or deposits have thus far been reported as having been found in any of these eruptives occurring later than the first flow of hornblende andesite. As these later rocks covered the entire region, only those portions of the earlier andesite, the ore carrier, are easily accessible which have been exposed by erosion. This will convey an idea of how uncertain prospecting in this district is, outside of a small area in which are the producing mines.

The main shaft of the Mizpah mine is down over 900 feet. The main workings are above the 600 level, and but little crosscutting has been done below the 600. The deepest workings on the vein are said to be at 540 feet, where a hanging wall drift has developed a vein 3 to 8 feet wide of high-grade ore, but the full width of the vein at this place has not been determined.

The Desert Queen shaft is down 1100 feet. It is a quarter of a mile east of the Mizpah main shaft. The Mizpah vein is stated to continue through the Desert Queen and Belmont ground, where it is about 6 feet wide, several hundred feet from the surface. There are several shafts sunk all the way in ore on this vein—the Brougher, down 700 feet, the Cutting and Lynch, each down over 300 feet. There are several other veins in the vicinity of the Mizpah vein, but as yet they have failed to produce the same high grade of shipping ore which has made the former lode famous. These outside veins, however, produce a good grade of ore, which will be milled in the local mills to be built in the district.

As in most other new mining camps of the West, Tonopah enterprise has exerted itself in the creation of distinctive and characteristic types of architecture, several samples of which are illustrated in the accompanying engraving. Here are seen a modern residence of substantial and homelike design; a house of bottles, and another built partly of bottles and partly of stone. Two others have been constructed of barrels, gunny bags and old tin cans, while another is more substantial and is built almost wholly of stone. In the desert city, frame houses and tent houses are to be seen by the hundreds. The mine improvements, however, are mostly of a substantial kind, and in some instances of higher class than are usually found in a mining district in the prospective stage of development.

### Deep Drilling in South Africa.

Diamond drilling as a means of locating the gold-bearing reefs of the Transvaal has been in general practice for many years. Unusual interest attaches

Boring a Hole 5560 Feet Deep.

this work larger and larger drills have been used, and within the past year or two enormous boreholes have been bottomed in ore at depths of from 4500 to 5000 feet. Over 300 diamond drills are now in use in South Africa. The mining companies, as a rule, let the work to contractors, who furnish all the equipment and expert operators, and deliver the core into the hands of the company. American companies have recently broken all records for depth. James Tobin completed a borehole last December at Doornkloof, 16 miles west of Randfontein, at a depth of 5560 feet. This hole was sunk to prove the main reef series, and it is understood that the results are conclusive, although they have not been made public. The deflection was very slight. The first 3200 feet were bored with a Sullivan size "N" drill, rated capacity 2000 feet. A size "P" drill, with a rated capacity of 4000 feet, was then put in commission and continued the hole until its completion at 5560 feet. Seven hundred feet of size "N" rods, removing 2 inch core, were used, the remaining 4860 feet being "B," removing a 1½ inch core. The total load of these rods was between fifteen and sixteen tons, which was handled by the engine without difficulty. The actual running time of this hole was fourteen months, or an average of nearly 400 feet per month. For the first two months two ten-hour shifts were used, and for the remainder of the time the work was carried on throughout the whole twenty-four hours, divided into three eight-hour shifts. The rods were pulled in lengths of 50 feet, the height of the tubular steel derrick being 66 feet over all. The time required to lower the rods at a depth of 5000 feet was from three to three and one-half hours, and from three and one-half to four hours were required to lift them. Herewith is illustrated the surface rig of this deep borehole.

This record has since been bettered by a hole sunk near springs east of Johannesburg, by John Skenke. This hole was begun May 1, 1904, and completed February 2, 1905, at a depth of 5532 feet. A size "P" drill was also used here, power being supplied by a 30 I. H. P. boiler. One thousand feet of "N" (2-inch core) rods were used, the remainder of the equipment being similar to that used by Tobin.

### The Walker River District, Nevada.

Written by DWIGHT T. SMITH.

The region about upper Walker river, Nevada, in a southerly direction from the village of Wabuska, has been described in a Bulletin of the Department of Geology of the University of California. The region is 30 miles east of Lake Tahoe and 20 miles southeast of Virginia City. In that section are a number of ore deposits which are described by the author of the Bulletin as follows:

**THE ORE DEPOSITS.**—The deposits of value carry copper and gold, but the two metals are not associated with one another in pay values. The richest copper deposits carry no gold, except perhaps as a trace, though occasionally a gold bearing vein contains copper, but not in values sufficient to warrant treating the ore for that metal alone.

**GEOLOGY OF THE DEPOSITS.**—In considering the general geology of the region the mineral veins are conformable to either one or the other of the main structural features of the region, and such being the case, it would seem that they were consequent upon the inauguration of these systems, but it is not to be inferred that they were formed subsequently to all the structural features. In fact, there seems to be very positive evidence that they preceded the present topography, which stands as a record of the later stages of deformation. In some instances there are a few veins that do not conform to either system.

That the mineral veins have preceded the present topography seems quite clear, and this is thought to be so for two principal reasons, which are, the absence of the veins from the rhyolite and the fact that the veins often reach to the highest summits. The latter condition would indicate that there is not now sufficient hydrostatic head under present conditions of surface configuration to bring the solutions from which the veins were formed to their present height. It may be remembered in connection with the first of these reasons that previous to the advent of the rhyolite the region was reduced to one of tolerably low relief. This evidently indicates that the vein formation was not active at the surface, and it was not until the later Tertiary, when the present ranges had been lifted and erosion had begun its work of uncovering them, that they became exposed.

The period of formation of the veins closed with the making of the present mountains in the Tertiary, but when it began is not so clear. Most likely it was after the effusion of the early andesite, for in one instance an andesite dyke forms one wall of a vein. It appears that no andesite remains residual near the metamorphics in which the strongest deposits of copper occur.

**THE DEPOSITS IN PARTICULAR.**—In a few instances the mining has progressed beyond the prospect stage. At the Ludwig copper mine a depth of about 400 feet has been reached. The ore occurs in chambers in limestone. These chambers when

taken together occur each more or less below the other, and when considered as a whole the idea of an ore chute nearly expresses their character. The chambers are along the contact between the iron ore deposit and limestone, which two occur as a simple outcrop having considerable length and a width of less than 100 feet. They do not meet squarely in this outcrop, but somewhat diagonally, hence there is a longer contact zone for the chutes. The rest of the country rock is granitic. The ores are sulphide, oxide and carbonate. At the Douglas mine the ore is chalcopryrite and chalcocite; the gangue is garnetiferous. About half of the ore is sulphide. It was apparently along the line of fracture that the ore solutions found their way. The country rock is in part almost wholly garnet and in part granitic, with small areas of limestone overlain. At the Blue Stoue mine the country rock is an almost entirely altered limestone. It is perhaps more than half epidote, and presents in the hand specimen a pale greenish gray color. This mass has been more or less fractured and refilled with calcite, in which the chalcopryrite is imbedded. The chalcopryrite is usually idiomorphic, at least it usually has one or two well formed faces. The rifts containing the ore betray some parallelism. The mine was named from a deposit of chalcantite (blue stone) which occurs near the surface. Farther south on this same ridge is the McConnell copper mine, where ore occurs mostly as an oxide. Oxidation has probably extended deeper there than any of the other places mentioned. Near this mine are several prospects, which usually are near a contact of limestone and granite. The deposits so far mentioned are all in or adjacent to the belt of schist. One reef of schist of a dark color, which is thus in contrast to the rest of the surrounding schist, crosses the summit transversely. In it there was found disseminated sulphides of copper and iron. The reef was supposed, on account of its strike and width, to be a dyke which had suffered along with the rest of the rocks the dynamic action which produced the schists. Sulphide was also found near the grano-porphry where it had been involved in the metamorphic action, but the sulphide did not appear to be so much disseminated as in the case of the dark reef.

Farther south of the McConnell mine gold occurs, and it also occurs in the Mason pass, to the north. There is also mineralization to some extent northeast of the Blue Stone mine, in the low hills near the west side of the river. East of the river are several veins of copper. They have a definite strike and dip, and are transverse to the summit of the ridges, and they occur along faults. There is not apparent the same amount of replacement of the wall rock or corrosion of the included breccia as in the case of the Ludwig and Douglas mines. Of these eastern ledges the Blue Jay has been most prospected. The mineralization in this case is confined to a belt about 200 feet wide along a fault. The ore, which at the surface is cuprite, occurs in cracks and fissures. The thin sections of the rock of this belt show more or less alteration of the rock and substitution of quartz which contains liquid inclusions. Sulphide ores make some appearance farther down in the prospect, and there has been considerable oxidation along the fault, and more particularly because it is vertical and in the bottom of a canyon. A hydrous copper phosphate, which the miners termed malachite, occurs in the mine, and from qualitative chemical tests made by the writer it appears to be libethenite; and from some goniometrical measurements made by W. T. Schaller of the United States Geological Survey it exhibits a few new forms. Also of some interest is the formation of chalcantite since the mining began. It appears to have formed in consequence of the steam which was introduced in diamond drilling. The remainder of the ledges occur from 2 to 6 feet wide, and the ore is much oxidized and leached. In some of the microscopic slides of the ores that have not been mentioned a very intimate relation of epidote to chalcopryrite is noticeable. The epidote occurs quite irregularly in outline, and the chalcopryrite tends to inclose it. The latter usually shows one or more quite distinct faces. This would seem to indicate that the chalcopryrite ceased to crystallize after the epidote and before the calcite or the quartz. In this connection it may be well to mention some of the considerations of a petrographical character that guided the writer in the study of the ores and their occurrence.

There appears as a corollary to many of the contributions to the subject of the formation of mineral veins, with respect to their structure, that relative idiomorphism and chemical phase cannot be regarded as having exactly the same significance that they have in the case of the igneous rocks. Their significance depends upon a different set of conditions. The banded structure frequently seen is due to a change in the solutions while the fissure is being filled; and as the filling starts on the walls and extends by successive layers or bands toward the middle, each mineral composing the layers is formed against a previous surface, and hence must have on one side the form of that surface. The other sides may not be freely developed on account of interference due to the minerals being contemporaneously grown. This is comparable to the allotriomorphic structure in granitic rocks. The bands may not show successively any regularity of

to it at the present time owing to the large number of deep holes which are being sunk to prove the existence and position of the ore bodies at increasing distances from the outcrop. For

chemical phase; one may be more acid than the next, or may be capriciously either, thus not possessing the regularity of the Rosenbusch order of crystallization. The writer was enabled to exemplify these propositions at the Steamboat Springs, which are near. This occurrence, as is well known, is often cited as an instance of vein filling now in actual progress, and consequently is one from which many of the ideas in regard to vein filling, including those on the crystallization of vein minerals, were derived. Another very good instance also occurs at Bridgeport, Mono county, Cal., near the source of the East Walker. It appears to have passed so far unnoticed. Instead of quartz being the filling material, a variegated travertine is filling the fissures. It is shown at this place, in addition to what is shown at the Steamboat Springs, how a portion of a vein may be formed without being directly attached to a previous surface. Hence idiomorphism has been taken in the sense just described in the study of the ores.

**AN OCCURRENCE OF NATIVE COPPER.**—One occurrence of native copper has been discovered. It is not extensive enough to have sufficient economic value to make the mining of it profitable, but a study of its origin was found to be of an economic worth. While the ore bodies themselves have been produced by aqueous solutions, this occurrence of native copper was produced by reduction due to the heat generated by subsequent dynamic action, and a close parallelism was thus found to smelting processes, and by chemical and microscopical investigation of the ore and rocks adjacent to the native metal many of the steps that have been taken in the reduction are revealed, with the result that several suggestions were obtained for the actual treatment of the ores, and thus an opportunity was offered for an improvement in the smelting formulas and some troublesome irregularities lessened.

### New Steam Shovel.

The Vulcan Iron Works Co. of Toledo, O., describes a series of equipment in steam shovels designed to embody the essential qualifications of a successful machine. The boom is constructed along the lines of box section construction, entirely of steel angles and

per shaft pinions with cut teeth. The shipper shaft is made with square seats for gear and pinion mounted into adjustable bearings.

The circle is made heavier than heretofore, roller bearings are also established in the "A" frame head, designed to contribute to ease and rapidity with which the shovel may be operated.

Car is made up of six heavy beams, four running full length; steel spreaders or separators are used in the car body for a rigid foundation upon which to build the operating machinery.

The boilers are of the marine return tube type and tested for carrying 150-pound working pressure, equipped with pump and injector water feed, pump feeding through hot water heater. All steam pipes, boiler and machinery, except on boom, is under cover. The house is of structural steel, enclosed with steel roof. The rear guys are double, of flat eye bar construction, adjustable to lower boom to height to pass inside of ordinary railroad dimensions.

These shovels are stated to be self-propelling under ordinary conditions, the propelling gear having a ratio power of 4 to 1, driving from both trucks.

### Gold in Coal.

Considerable attention has been given the past few months by various observers to the occurrence of gold in coal. Jas Chenhall, in a paper read before the Institution of Civil Engineers, describes the Cambria coal fields, situated in Weston county, Wyo., about 65 miles from Deadwood, S. D., and says the attention of geologists will be especially attracted to the fact that this coal carries values in gold. This is sufficiently important to make one wish that the geology of the field had been given. The references to this should be given in the author's own words: "Sulphur and iron are present in some portions of the coal in the form of pyrites. Sometimes as high as 2% of sulphur is found. The pyrites are very unevenly distributed throughout the seam." After references to the quality and uses of the coal, the author adds: "Its only drawback is a high percentage of ash, but compensation is made in the case of smelting the precious metals by the fact of this coal and coke

report in this paper, F. B. Stephens, lecturer on metallurgy at the Otago University, subsequently director of the Stawell School of Mines (Vic.), and manager of the Cassilis G. M. Co., Gippsland, wrote as follows: "The report is correct. In 1895 I happened to be assayer for the Buffelsdoorn Estates & G. M. Co., Klerksdorp (S. A.), when the discovery was made. The ore mined was quartzite, and occasionally showed patches of banket. Running through the quartzite in many places were small seams of coal of the nature of anthracite. Some of this coal assayed as high as 800 ounces of gold per ton. The gold was exceedingly fine, and was not apparent at a casual glance, but on closer examination it could be seen very thickly peppered through the coal. The ash of the coal was colored bright purple from the amount of gold it contained. One small seam that was found lying flat against an intrusive mass of diabase looked like honeycomb, the gold taking the place of the honey. Strange to say, it was only where the quartzite was cut through by the dyke that the coal contained any gold. In other parts of the mine the coal was quite barren. The coal contained iron pyrites, and without doubt the pyrites in contact with the coal deposited the gold from solutions which had found their way up the dyke fissure, the gold most likely being dissolved out of the underlying auriferous strata. I never communicated the discovery to any scientific paper before, but several well-known geologists received samples of the coal."

The occurrence of gold in coal is also reported from Colorado, and it is not improbable that gold may occur in coal more commonly than is generally supposed, particularly in the gold regions where coal is also found.

### Grading Analyses.\*

Written by H. S. DENNY.

In reducing an ore to pass a mesh of 600 holes to the square inch it may be taken as an axiom that we have practically every variation of fineness between that mesh and infinity in the finished product. In other words, it may be stated that the means adopted to arrive at a required product, all of which will pass a 600-mesh, will also ensure the passing of a large percentage of that product through a much finer mesh. Hence arises the necessity for what we are accustomed to term a grading analysis. It is a matter of considerable surprise to me that this question has not been ventilated more freely by the technical societies here long ago, as, in my opinion, there is a demand for uniformity and agreement both as to the meaning of the term and as to the most suitable method for handling the operation. I have frequently known the term "grading analysis" to be made use of, but no definite and generally accepted meaning can be said to have been arrived at in its particular application to ore reduction on these fields. The first thing, therefore, that we must agree upon is the exact interpretation to be placed upon it, and to this end, after careful consideration, I submit the following suggested definition: "A grading analysis is the determination in any finely ground auriferous product of the percentage and value of two or more size-classified divisions of that product."

The objects of the analysis are briefly as follows:

1. To show clearly the percentages of certain arbitrarily fixed degrees of fineness in the ground product.
2. To enable the operator to arrive at the gold value of such percentages.
3. To enable the operator to judge of the relative amenability to his methods of treatments of ore in the various stages of comminution lying between coarse particles and very finely divided particles having particular regard to gold extraction.
4. To enable the operator, by virtue of the above information, to fashion his treatment practice to gain the maximum extraction.
5. To assist the operator to ascertain where his extraction is at fault and where his gold loss in residues lies.

It will be observed in the statements elsewhere given that the classifications adopted in the mines with which the writer is connected are as follows:

Percentage remaining on 60	$60 \times 60 = 3,600$	screening.
Percentage remaining on 100	$100 \times 100 = 10,000$	"
Percentage remaining on 150	$150 \times 150 = 22,500$	"
Percentage remaining on 200	$200 \times 200 = 40,000$	"
Percentage passing 200	$200 \times 200 = 40,000$	"

This series can naturally be altered to give either greater or less detail, but for our particular purposes it fulfils all practical requirements.

**DRY AND WET ANALYSIS.**—Despite all the experiences of the past two years, I am still in doubt as to which particular method of analysis gives the more reliable and consistently average results, and, in order to make my perplexity apparent, I can not do better than lay the brief reports of four mine managers before you, each report representing an emphatic opinion on the question, and each differing from the other. Most of the important considerations in the subject under discussion are touched upon in one or the other of the four reports, and I

\* Abstract Trans. S. A. Assn. Engrs.

plates, braced internally to withstand intermittent strains. It rests in a steel trunnion at the foot, and is supported at point by wrought iron stirrups. These stirrups are connected to the "A" frame head, with double flat eye bars. The dipper handle is of steel I beams, stiffened with channels and bars; the packing of wrought iron with cut teeth, each side in one continuous piece, bolted to flanges of stiffer channels. Three styles of dippers are offered in this construction—round, square or semi-square—according to the class of material to be dug. For convenience in finishing slopes, etc., the dipper is adjustable to any pitch. The mouth piece and wearing plates are of manganese steel, teeth of hammered iron, with tool steel or manganese adjustable points. The dipper handle operates over wrought steel ship-

containing a small quantity of gold and silver. Some samples have given as high as 3 dwts. of gold to the ton of coke, but the average is between 1 dwt. and 2 dwts. of gold to the ton. This is the first time that the author has found gold and silver in the ash of coal. Coke from these mines is almost exclusively used in the gold smelting works at Deadwood, in the Black Hills, S. D."

Another writer says though the presence of gold in coal may be new within Mr. Chenhall's experience, it is by no means a unique occurrence. A few years ago, in the end of 1899, to be precise, a similar discovery was reported from Gippsland. Miss E. Felstead of St. Kilda, found gold in a small piece of household coal. Gold has also been found in South African coal, and when a doubt was cast upon the

do not think that a better basis for a further and more complete investigation could be provided. I shall describe the reports as "A," "B," "C" and "D," and they are as follows:

**REPORT "A."**—Sieving.—The screens, sands residues and sands charges are all graded dry (the slimes only being graded wet), using the following sieving—3600, 10,000, 22,500 and 40,000 mesh per square inch. These four sieves all fit into each other with a cover and tight-fitting bottom compartment, forming a nest of sieves. When grading, the sieves are all superimposed, the weight sample being placed on the top or coarsest sieve, and the nest is well shaken, the cover being occasionally removed and the ore rubbed over with a camel hair brush, each grade being finally finished separately over a sheet of glazed paper; when no more will pass that particular sieve, the contents are emptied out and put aside for weighing, the same routine being repeated until all that is possible is obtained of each grade, the balance having passed through into the bottom of the compartment.

**Sampling.**—Out of all the daily screens, sands-charges and sands-residues samples, 2000 grains are kept, which is put aside until the end of the month, when the whole sample is placed on the sample table, well mixed and quartered down to a convenient size sufficiently large to allow repeating should it be necessary.

**Quantities.**—There are 20,000 grains graded from the screens sample, and 40,000 grains from sands charges, sands residues and slimes samples.

**Slimes.**—In grading slimes samples there are only two products to be considered—viz., sands and slimes. The 40,000 grains of slimes are weighed, and a portion is then put into the 40,000 mesh sieve, a large enameled dish is placed on the bench, and the clean water tap is connected with a short piece of India rubber tubing, the other end of which is used for playing a gentle stream of water on the sample so as to wash all the slimes through the sieve. The water hangs back in the sieve, owing to the fineness of the mesh, but by frequently rubbing over the slimes and water with a large camel hair brush the slimes are all gradually washed through, and only clean sands remain on the sieve. These sands are dried and weighed and the percentage of slimes obtained by difference.

**Wet and Dry Methods.**—From our experience in comparing wet and dry grading analyses, it is very noticeable that when using a nest of sieves constantly for wet work, the screening stretches very considerably, and therefrom a great irregularity arises in the results obtained, as proved by the differences in running two lots of the same original sample through. On the other hand, when grading dry and using a tight-fitting cover and nest of sieves with a minimum of dusting, concordant results can be obtained over and over again.

**REPORT "B."**—The method adopted on this property is the wet one. The japanned sieves are arranged in their correct order, and the sands are gradually fed into the top sieve and washed through as far as possible. When this sieve is cleared of all slimes—this point is denoted by the clearness of the water—it is removed, and the remaining sieves in order treated in the same manner. After the various products have been thoroughly dried they are returned to their original sieves and shaken for a few minutes, to insure that none of product 2 has remained with 1 or 3 with 2.

The amount of ore taken is 1000 grammes, equal to about 2 pounds avoirdupois. This quantity is chosen to simplify the working out of percentages.

**Wet and Dry Methods.**—Although the wet method takes a longer time, it has the advantage that the point when the finest product—i. e., that which passes the 40,000—has been eliminated, is more clearly defined. There is also to me some doubt as to whether in the dry method the original condition of the ore under examination may not be altered by attrition.

**REPORT "C."**—I have tried both wet and dry methods of grading, and have lately adhered solely to the former, it being in my opinion better for the following reasons: (1) Entire absence of loss from dusting, which is always more or less in evidence in the dry method. (2) Much less time is occupied, as the operation can be pushed without fear of loss. (3) The results of the wet method show much less variation, and, I consider, are more reliable than dry. The one objection I have to the wet process is that it necessitates settling slimes, decanting water, and subsequently drying of the product. As regards the wear of screens, I do not find much difference in this respect between the two methods.

**REPORT "D."**—Locally-made sieves are used—18 inches diameter and 3 inches deep—with the screening specially supplied; 1500 grammes are taken of the sample and first treated on the 200 mesh. The reason for separating the finest portion first is that the presence of the coarse particles keeps the mass more open, avoids the clogging of the fine mesh, and thus facilitates the passage of product through same; the amount of fine product is also at once eliminated. The actual separation is then made by gently shaking the sieve laterally, varied with the circular motion as in panning, and constant tapping on the frame of sieve. The latter method appears to me most

effective, especially when nearing the end. The separation is considered complete when by placing a clean sheet of paper under the sieve and continuing the shaking, etc., for a few minutes longer, an unweighable quantity only is obtained. During the operation no brush or other means are used to assist the material through the mesh. The residue is then transferred to the coarsest (60 mesh) sieve, the operation as before repeated, and subsequently continued with the 100 mesh and 150 mesh, respectively. In the earliest stage of grading practice a nest of sieves was procured, the diameter being 9 inches and the depth 2 inches, but the sieving was found to be very tedious and very slow, and in order to deal expeditiously with the comparatively large amount of samples that was required in order to get sufficient of each product to determine its gold value, water was used both with a jet and by partly immersing in the water the sieve and contents, and agitating, etc. This method answers admirably for the quick separation of the fine or slimy portion, but it was not at all satisfactory in separating the coarse particles; the difficulty lay in getting a satisfactory ending to the small particles persistently, and in small quantities going through. This could not be obtained by the gentle impinging of a jet or by the continuous and prolonged shaking and mixing with or without spatula or brush, or by any other manner that could be devised. An average of four separate analyses by the wet method gave a 20% higher result for the product that remained on the 60 mesh than a similar number by the dry. The cause, I believe, is that the particles of the 100-mesh (and finer) product have not sufficient weight in themselves to at once settle in disturbed water, and find their way through the mesh—this point may be clear if the suspensory

quickly or of enlarging its meshes, how often should a screen be used, and what check can be applied to determine its condition?

8. Is the possibility of loss from dusting a serious drawback to the dry method?

9. Is the possibility of attrition more accentuated in the dry than in the wet method?

**WET METHOD.**—1 to 5. Same as under dry method.

6. Is the screen worn more rapidly by the wet than by the dry method?

7. Same as under dry method.

8. In sands and slimes residues, is the point raised in Report "D," re gold in solution being washed away, important enough to condemn the method?

The above points represent in brief the problems under either method, and it may be that there are members of this society who have engaged these problems in the past, and their experience would be useful in finally deciding on the correct procedure. In the meantime I am of opinion that the results from either method employed should be checked as often as possible by the other method. There is no doubt that all the points above raised can be settled by careful experimenting, and it seems to me that the value of the work is such that experiments should be conducted regularly on every mine on the fields. I might add that if I had to choose one of the two methods above, my inclinations would be in the direction of the dry method.

**RECENT ANALYSES AT VAN RYN.**—The following statement represents the grading analyses of samples carefully taken over periods of several months at the Van Ryn mine. I have thought it better to give this statement in full and over several months, so that comparisons can be made as between month and month:

effect on slimes is considered—and, furthermore, the wetness itself causes adherence of the particles.

It might be thought that a jet of water must necessarily carry through the mesh any particles sufficiently small, but mention must be made that only a weak jet can be employed, otherwise loss of sample by splashing would occur, and any pressure that would expand the mesh is to be avoided. The impracticability of using the wet method with sands and slimes cyanide residues is demonstrated by the soluble gold being carried away in the wash water.

It may be assumed that all the particles of silica upon their exit from the mortar box are in a more or less fractured condition, and therefore all shaking, etc., in the subsequent sieving operations—in addition to self-attrition—must increase the fineness. The use of a brush or other means to assist the passage through the sieve has the effect of expanding the mesh, especially the very fine hair-like wires of the smaller sizes. A similar danger may result by the weight of a large sample pressing on the mesh of a large area sieve. After a sieve has been in use a few times the threads become worn and stretched.

A study of these reports will show that there is considerable diversity of opinion as to the relative merits of the "wet" and "dry" methods. "A" recommends the dry method for screen, sands charges and sands residue samples, and the wet method for slimes. "B" for all samples uses the wet method first, but as a final test applies the dry method. "C" is emphatic on the superiority of the wet method. "D" is just as emphatic on the superiority of the dry method, and has entirely discarded the wet method. The queries that arise on the respective methods are interesting, and on their settlement will depend the final method to be adopted. They are briefly as follows:

**DRY METHOD.**—1. Of what material should the screen be made?

2. What should be its dimensions?

3. What weight of sample should be taken?

4. Should the sample be treated first on the 200-mesh screen? (vide Report "D").

5. Should a brush or other instrument be used to agitate the sample on the screen? (vide Report "A"). Or should a gentle shaking or tapping on the screen be adopted? (vide Report "D").

6. By placing the glazed paper under the screen can we arrive at a satisfactory determination of the completion of the operation?

7. In view of the danger of wearing the screen

Taking the Van Ryn statement, we find in the screen sample that:

The percentage remaining on 60 mesh varied from..... 27.45 to 29.15  
The percentage remaining on 100 mesh varied from..... 20.37 to 21.42  
The percentage remaining on 150 mesh varied from..... 7.16 to 9.7  
The percentage remaining on 200 mesh varied from..... 4.6 to 5.81  
The percentage passing 200 mesh varied from..... 35.69 to 37.95

(TO BE CONTINUED.)

## The Simplon Tunnel.

The piercing of the Simplon tunnel a few days since, says Page's Weekly, is the culmination of one of the most striking engineering feats of the present day; it is a remarkable instance of the triumph of mind over matter. The long anticipated juncture of the north and south sections of tunnel appears to have admirably fulfilled the calculations of the engineers. Napoleon's road over the Simplon was commenced in 1800 and finished in 1806. It still offers the route for those who are in search of scenery and whose time is unlimited. The new tunnel pierces the Alps at a lower elevation than any other route, viz., at 2300 feet above sea level.

With the exception of a short curve at each extremity, the route follows a straight line. It is a double tunnel with two parallel sections, 55 feet from center to center, each designed to carry a single line of rails. As yet only one of these has been constructed completely. The other, consisting at present of a gallery some 6½ feet high by 10 feet wide, is used for ventilation and purposes of construction. According to the international agreement between the two countries, it need not be completed as a second tunnel until the gross receipts from traffic between the tunnel termini exceed £3218 per mile per annum.

The exact length of the Simplon tunnel is 19,731 kilometers (12½ miles); it is, therefore, by several miles the longest tunnel in the world. The mountain towers above it over 5000 feet on the average, and 7000 feet at the highest point. Cross-headings connect the two tunnels at intervals of 656 feet. The extreme height of the tunnel is 18 feet above rail level, its width varying from 14 feet 9 inches at the latter point to 16 feet 4 inches at a height of 6 feet 6 inches above rails. The center of the tunnel is for a distance of 1310 feet of wider section, in order to admit of trains passing. From this mid-distance there is a gradual slope to both termini—that on the north side having a ruling gradient of 2 per 1000, while

that on the south side has a ruling gradient of 7 per 1000. The contract price for the tunnel is over £2,350,000; but, of course, the actual cost is as yet an unknown quantity.

The execution of this remarkable work has called for admiration all along the line, whether one considers the mechanical perfection to which the contractors brought their machinery or the organization of the 3000 men employed, who appear to have worked with an undivided enthusiasm and an almost military precision. It says something for the brains employed upon the scheme that, in spite of the most trying conditions, an excellent standard of health has been maintained among the workers, the most careful arrangements having been made to protect them

litre of water per second. The two cylinders are connected by cross waterways and the piston of one acts as the valve of the other. The speed of the cutter necessarily varies for different densities of rock, but its highest speed is ten revolutions per minute. The drill, as described, is mounted in groups of two or more on a heavy iron thrust bar, about 12 inches in diameter. The figures are from the Engineering News.

In the process of excavation followed it has been usual to make an advance heading, 7 feet 10 inches

was stopped by hot springs.

An engineer connected with the work deals in the Times with some of the difficulties encountered: The gradient ascends from each entrance towards the middle of the Alps for drainage purposes, and it is due to this that it has been possible to carry on the work, as the yield of the great springs flows away by gravitation. At 4400 meters from the Italian entrance a very large spring of cold water of 12,500 gallons per minute—in fact, a river—was struck, and this caused several months of delay at this end of the

Map Showing Proposed Routes of Simplon Tunnel.

from the dangers attaching to sudden changes of temperature and wet clothes. Most careful attention has also been given to vital questions of ventilation and commissariat.

An important factor in the rapid execution of the work has been the drill shown in Fig. 4. The feed of the rotary cutting tool is accomplished by the direct pressure of water in a large cylinder, the piston of which returns automatically when the water supply is cut off. The mandril carrying the boring bar and also the cutter are driven by means of two cylinders located above the feed cylinder. These cylinders operate a shaft having a worm gear which meshes with a worm wheel centered on the mandril. The cylinders are 1½ inch in diameter and their pistons have a stroke of 2½ inches. They are operated by hydraulic pressure, and each uses normally one

by 10 feet 8 inches, by means of the power drills. This has been timbered and covered in for the passage of compressed air locomotives and trucks. From this a shaft was driven to the roof line every 164 feet, and from these the tunnel has been opened out both ways to the complete section. Dynamite and blasting gelatine have been the explosives used at the Italian and Swiss ends respectively, and, as a rule, eight blast holes were drilled at the face, the machinery and men being withdrawn for refuge to the cross galleries or service tunnel. In 1898, 1342 feet were bored, each of the successive years up to and including 1903 being responsible for over 11,000 feet; while in 1904, 5457 feet were excavated, and during the present year 557 feet have been taken out. The work, of course, proceeded simultaneously from both ends, but in May last driving at the Brigue end

tunnel. The ground was very treacherous, so that it had to be heavily timbered; the stoutest and largest timbers were crushed, and steel girders had to take their place; but so great was the weight that these were twisted and distorted, and finally were only held in their place by being strengthened with concrete in cement. This enabled the driving of the gallery to proceed, but meanwhile the Brigue end had reached the top end of the gradient in the middle of the tunnel, although the rock temperature had risen to 132° F., fully 25° more than had been expected. With a view to saving time, it was then decided to continue this and drive down the Italian gradient to meet the corresponding tunnel coming up from Iselle, although it was quite anticipated that difficulties would be met with in driving down hill. In this the contractors were not deceived, for very soon hot springs of 111° F., and of considerable volume, were met with. These springs are far hotter than is bearable, but the engineers adopted the comparatively simple expedient of throwing jets of cold water into the fissures and thus reducing the temperature as far as was necessary. The cold water is driven into the tunnel by centrifugal pumps, through pipes surrounded by non-conducting material, so that the water is delivered as cool as possible.

Meanwhile the work at the Italian face was pushed on, until in September last another hot spring of 114° F. was encountered in each of the parallel galleries, amounting to about 1800 gallons per minute, and considerable difficulty and great delay were caused. By dint of extraordinary perseverance and courage, these springs were passed and soon left behind by the drill. The volume of water then emitted from the tunnel was still about 12,000 gallons per minute. When the actual junction of the galleries was effected the accumulated hot water on the Swiss side found its escape into the south gallery, and was discharged into Italy.

The work that now remains to be done is to put in place the masonry arching, to cover over the water channel beneath the floor of the tunnel, and to lay the permanent way.

### Mining Enterprise in Colorado.

Written for the MINING AND SCIENTIFIC PRESS.

Clear Creek, Colorado, is one of the leading mining counties of that State. It was in this county that gold was first discovered in Colorado, in 1859. The principal veins found during the early history of the county were gold bearing. Near Georgetown a number of veins first worked for gold were later found to be rich in silver also. The several important towns sprang rapidly into an energetic and well-founded existence. Among them were Georgetown, Idaho Springs, Empire and Lawson. Thousands of miners hurried into the district and the mines were developed rapidly. The placers yielded famously, both gold and silver, and strangely less attention was paid to gold than to silver in those early days. Among the most noted mines of the early days were the Pelican-Dives, Seven-Thirty, Colorado Central and Empire, near Georgetown; the Red Elephant, near Empire and Lawson, and the Fremont, Lamar

Nails, per keg	20 00
Coal oil, per gallon	5 00
Miner's wages, per day	4 00
Team and driver	12 00
Milling charges, per ton	5 00
Smelting charges, per ton	60 00
Freight, per ton	25 00

The prices on some of the items to-day is but about 20% of those given above.

During the two years following the discoveries on McClellan mountain miners rushed into Clear Creek county from every direction and rich mines were discovered on the mountains all about Georgetown. In 1867 several smelters were erected, but none of them were very successful in reducing the ore from these mines at that time. Some of the ore found on McClellan mountain, which, it is said, showed no trace of silver minerals when examined with a magnifying glass, still assayed upward of 100 ounces silver per ton. The silver was so closely associated with the galena and blende that it could not be seen.

The accompanying illustration is that of McClellan mountain, showing the dumps of the Colorado Central mine.

The development of the early days not only furnished a large amount of ore, which proved highly remuner-

mountains for thousands of feet, crosscutting the country and developing the numerous gold and silver veins at great depth.

The Stevens mine, owned by the Waldorf M. & M. Co., was one of the first noted mines in Colorado. The Waldorf Company is one of those which has undertaken the consolidation of large interests on McClellan mountain, and the driving of a great tunnel to develop the veins in depth. As announced in these pages last week, the Waldorf tunnel is now in 3800 feet, and is reported to have cut forty-four veins, at least thirty of which contain a grade and amount of ore which will pay for shipment. The tunnel is cutting veins at depths ranging from 500 to 1500 feet lower than the deepest old workings made from the surface. When completed the Waldorf tunnel will be over 9000 feet in length. Its line intersects ninety-five known veins, nearly half of which have already been intersected by the tunnel.

Another prominent mining enterprise, similar in object and result to that of the Waldorf Company, is the Vidler tunnel, which starts on the east side of the divide in Clear Creek county and, running 7000 feet, will open on the west slope in Summit county.

McClellan Mountain, Clear Creek, Colo.

time and Stanley mines, near Idaho Springs. It is said that during this period "fighting men" were paid \$10 per hour to watch the location stakes and monuments until the claim could be properly staked and the location placed on record in the Land Office. Georgetown was a very prosperous town at that time, and the surface workings of the mines netted their owners hundreds of thousands of dollars. The first prospecting for silver was done in 1864 when Huff, Layton and Steele discovered the Belmont Lode, on McClellan mountain. The surface ores gave high returns in silver and shipments commenced from the croppings. In those days silver was a good price, but smelter charges were four or five times higher than now. Freight also was much higher, as well as the cost of tools and all kinds of supplies, and labor was better paid then than at present.

A comparison of the following figures—prices as late as 1870—with those obtaining in that district to-day is interesting:

Steel, per pound	\$ 0 40
Iron, per pound	25
Rope, per pound	60
Nitro powder, per pound	1 00
Detonators, per hundred	3 00
Fuse, per 1000 feet	30 00
Lumber, per 1000 feet (B. M.)	60 00
Candles, per box	20 00

ative to the owners, but it also left available large amounts of ore too low grade to be profitably extracted and treated at that time, but which is available to-day.

The railroads were the main factor in the development of new conditions. Supplies were obtained more readily and at greatly reduced cost. The era of excitement passed away and mining settled down to a more conservative and business-like basis. The depreciation of silver was for a time an almost fatal blow to the progress of the mining industry about Clear Creek county, but, fortunately, as silver went down in price, lead and zinc went up, and as the great leads of these mountains carry vast amounts of both lead and zinc, it has enabled the miners of that section to not only prosecute their business, but to make large profits from it as well.

The discovery and rapid development of such camps as Leadville, Cripple Creek and Creede drew heavily on the best mining talent of Clear Creek county, and many of its most energetic and experienced men left to try fortune in the newer camps, but others—equally energetic, experienced and resourceful—remained. Some of the greatest mining schemes in the State of Colorado are slowly developing in this county. These are the tunneling of the

Good progress has been made in this tunnel, which is 10x10 for 250 feet and then reduced to 8x8 for the remainder of the distance.

What is known as the Kelley tunnel is being driven under Democrat mountain to develop a large group of mines. It will cut some of the veins 3000 feet below their apex.

The Newhouse tunnel is in under Seaton mountain, nearly 3 miles, and will eventually tap the veins of the district about Central City.

In addition to these, there are numerous other tunnel projects of greater or less magnitude, in operation or projected. It is said officially by the State Commissioner of Mines of Colorado that the number of crosscut tunnels in Clear Creek county is greater than in any other section of the State. The mountains rise abruptly, and quickly give good working depth to the tunnels, and the veins apexing on the surface having been found almost uniformly to persist in depth proves that this method of exploration and working is justified, as shown by the results.

The geology of the Clear Creek region is thus described by the State Mine Commissioner:

"The geological formation is that common to the front range of mountains, viz., granite, gneiss and schist, and is traversed by a series of eruptive dikes.

The mineral bearing veins are of the fissure type, and the precious metal deposits were, in the main, subsequent to the dikes. Not infrequently the vein is in direct connection with the dike which forms one of the vein walls, or may locally constitute the vein material itself. The dikes are of frequent occurrence, of variable size and character lithologically, but are all generally called porphyry. The mineral bearing veins are, in the main, roughly parallel to, when not in conjunction with, the dikes. While the dikes and veins show variable strike, the most persistent and common course appears to be from north-east to nearly east, with a northerly dip. The north and northwest veins are less prominent and generally not so persistent in mineralization. The ore veins vary in width from a few inches to zones or vein systems of 100 feet or more. Generally, the vein walls are well defined, quite hard, and separated from the vein proper by a thin selvage or 'gouge' material. Locally, however, the 'pay ore' or 'mill dirt' may impregnate the adjoining country for some little distance.

"The vein filling is generally an altered condition of the country rock, more or less impregnated with variable sulphides. The main values, however, occur in form of ore shoots concentrated near one wall. The shoots are more or less persistent longitudinally, in many places showing the ribbon structure, and vary from a narrow streak to a foot or more. The associated low-grade ore bodies are generally larger. This common condition has caused the parlance of the district to designate the two ore bodies as 'pay or smelting ore' and 'mill dirt or mill ore.' The ores are mainly sulphides of iron, copper, lead and zinc, with associated gold and silver values. Under former market conditions, the mines adjacent to Georgetown were worked for silver output, and established an erroneous belief that gold existed only in minute quantities in the western part of the county. The changed conditions have caused a search for gold bearing ores, and the imaginary line that divided the gold bearing and silver bearing areas has been obliterated.

"The most common method of mining is to break the mill dirt, leaving the smelting ore to be taken down separately. This latter is assorted, the refuse put with mill dirt and the choice ore shipped direct to the smelter. Some shipments of assorted ore are very high in gold and silver values. As a rule, the ores are amenable to the ordinary methods of amalgamation and concentration, and mills of this character are found in all sections."

### How to Use Portland Cement.

Care at all times should be taken in mixing concrete to use only clean, sharp sand (free from loam or soil) with pebbly grit, old broken bricks, stones or slag. Portland cement, either in casks or bags, must always be kept perfectly dry till used, damp being very injurious, causing it to become lumpy and useless. Brickwork and bricks or stones should always be well wetted or soaked in water before using.

When cement plaster is used for facing brickwork the joints should be deeply cut out and well sluiced and wetted with water, after which it may be plastered, taking care to always keep the edges wet and face damp till finished, and to prevent its drying too quickly. Good results will be found from damping the surface again with a whitewash brush and water, as drying slowly makes better work with more certain results.

Strong Portland cement is heavy, weighing 90 pounds to the cubic foot. Weak cement is lighter, but weight is an unsafe test for cement.

Strong Portland cement is of a blue-gray color and sets slowly. Weak cement sets quickly, has too much clay in it, and is of a brownish color.

The cleaner and sharper the sand, and the less water used in mixing the cement, the stronger it will be.

	1 in.	THICKNESS	3/4 in.	1/2 in.

1 bbl. cement and 1 bbl. sand will cover..	72 feet	96 feet	144 feet	144 feet
1 bbl. cement and 2 bbls. sand will cover..	108 feet	144 feet	216 feet	216 feet

**CONCRETE.**—One barrel Portland cement, two barrels clean, sharp sand, five barrels broken stone or hard burnt bricks or clean gravel or shingle will yield about 20 cubic feet.

**FOOT ROADS.**—One barrel Portland cement, one barrel clean, sharp sand, three barrels finely crushed firebricks or hard common bricks laid 2 inches thick on a firm foundation of 4 or 6 inches thick of broken stone, well rammed and ground-drained well.

**COATING IRON SHIPS.**—Equal parts Portland cement and clean, sharp sand or finely ground bricks, and laid about 1 inch thick.

It having been frequently found that samples of Portland cement taken from the same bulk have exhibited varying results as to strength and color (the cause thereof being the different methods of mixing employed), the following suggestions will be found valuable to consumers:

1. The cement should be perfectly cool when used. If heated it will become outwardly scorched, and consequently be of a bad color.

2. Cold and clean water should be used in mixing

cement to the consistency of common mortar, as hot water will injure the strength and color. Too much water will make it soft and useless.

3. Care should be taken that the sand used with the cement is of good quality—sharp, clean and well washed from all earthy substance—or the best cement will show inferior results.

4. The cement should be used as quickly as possible after it is mixed. The practice of partially mixing and afterwards remixing is most objectionable, as it destroys its setting properties. It should be allowed to dry naturally, artificial heat being highly injurious to cement.

5. The work should be first well wetted, and when the cement has commenced to set the process should not be disturbed, as if so it cannot be renewed.

6. For stuccoing, the walls should be well cleaned and wetted, and the first coat ought to contain three to four parts sharp river sand to one of cement. When hardened for the second coat, two or three parts of finer sand should be used to one part of cement.

7. For mouldings, use equal parts of cement and fine, sharp river sand.

8. For flooring granaries and maltings, level and well ram the floor, fill up to the required thickness with one part of cement to three or four parts of shingle or broken bricks, and finish off with a float. If the surface is required smooth, it should be overlaid by a thin covering of equal parts of cement and fine sand. When the cement has set, it will benefit by covering the floor with water for several days.

9. For reservoirs, gas or water tanks, use one part of cement and two or three parts of sharp, washed sand for the brickwork, and coat the inside with pure cement.

10. For breakwaters and harbor works, blocks may be formed in moulds to any size required (at the harbor works, Dublin, they are made 350 tons each) by mixing six parts of coarse but clean gravel with one part of cement, into which may be inserted about one-fourth rubble stone. Blocks thus made must be allowed to become thoroughly set before they are disturbed. They will then resist the action of the sea, and become harder and stronger with age.

11. As to storage, great care should be taken in selecting a place for the storage of the cement. If exposed to damp or heat, all cements will rapidly deteriorate in quality. Where a perfectly dry place is available, it will be found advantageous to empty the cement out of the sacks or barrels, allowing it to remain on the floor for a time, exposed to the dry air before using it.

The longer it is setting the more its strength increases.

Neat cement is stronger than any admixture of it with sand.

Cement mixed with equal quantity of sand in a year has approximately three-fourths the strength of neat; mixed with two parts of sand, one-half the strength of neat; mixed with three parts of sand, one-third the strength of neat; mixed with four parts of sand, one-fourth the strength of neat; mixed with five parts of sand, one-sixth the strength of neat.

The cleaner and sharper the sand the greater the strength.

Very strong Portland cement is heavy, of a blue-gray color, and sets slowly. Quick-setting cement has generally too large a proportion of clay in its composition, is brownish in color, and turns out weak if not useless.

The stiffer the cement is gauged—that is, the less the amount of water used in working it up—the better.

It is of the greatest importance that the bricks or stones with which Portland cement is used should be thoroughly soaked with water. If under water, in a quiescent state, the cement will be stronger than out of water. Cement kept in water is one-third stronger than that kept out.

Blocks if kept in water should be stronger.

Salt water is as good for mixing cement as fresh.

Whenever used under water, care must be taken that the water is still, as otherwise a current, whether natural or caused by pumping, will carry away the cement and leave only clean ballast.

**CONCRETE.**—Much harm is done, time wasted, and annoyance caused by the habit of inexperienced persons picking and poking cement samples of work before it has had time to get strength. To such persons quick-setting, light-weight cements would appear to promise good results, but it is now well known by every one practically acquainted with the use of cement that the well-burned, heavy, finely-ground, slow-setting cements are the best for concrete purposes.

The water used for mixing concrete should be clean. It is possible to destroy much of the strength of cement by using dirty or polluted water. Sea water has not been found to be injurious, but it is supposed to delay the setting. Respecting the quantity of water to be used, there is more danger to be apprehended from using less than from using more than the right quantity. The correct quantity is, of course, sufficient to convert the cement into a thin paste, that shall completely coat and cause to adhere all the particles of the aggregate.

Concrete mixed by hand is preferable, as it is important to have the materials all mixed dry before

mixing with water. Crystallization, or setting, begins at once with the addition of the water, and as little time as possible should be spent in thoroughly mixing and placing into the mould or apparatus after water has been added. There are many various concrete mixing machines, most of them being unnecessarily complicated, the best being a plain revolving cylinder, working horizontally. Concrete mixed in machines is generally over-mixed after the addition of water.

The only liability to defects in cementing on concrete walls or floors is where two coats are used, and when idle and ignorant workmen, to save themselves trouble, use too large a proportion of cement for the thin finishing coat. Then, in consequence of the variation in the contraction of the two coats, the outer one is liable to show fine surface—or, as they are often called, sun—cracks, and even in some cases to peel off. Of course, this liability, being known, can be easily provided against.

### Hints to Aid the Identification of Stream Tin.

Written for the MINING AND SCIENTIFIC PRESS by  
CHAS. H. WALKER.

Although the ore known as cassiterite is the mineral from which metallic tin is principally produced, a comparatively small proportion of this mineral is mined from veins and ledges, most of it being extracted from the drifts and gravels of rivers and creeks, where it occurs in the form known as "stream tin." In stream tin we have a mineral which, owing to its mode of occurrence and its weight, can be easily and economically won by the simple method of "ground" or "box sluicing." Under normal conditions the primitive outfit of the placer gold miner, subject to some trifling alterations in the size and shape of flumes and boxes, is absolutely all that is required in order to recover this ore as a concentrate containing about 75% of metallic tin.

To the inexperienced eye the appearance of stream tin ore would not suggest that its metallic contents were worth approximately \$600 per ton. The ores of gold, silver, copper and lead often have a metallic luster, which even to the uninitiated hints of the wealth they may contain. Not so, however, with cassiterite. It is a common, unattractive mineral, showing little outward indication of its intrinsic value. The world's tin supply comes from comparatively restricted areas in widely separated parts of the earth, and it appears somewhat strange that in a continent of this size, which must contain large areas in which the geological formation is favorable for its occurrence, hitherto this mineral has not been discovered in any large or payable quantity. Wherever payable tin has been discovered the production has been usually of a permanent nature—a source of great natural wealth—and its mining has given remunerative employment to many thousands of men. Over two thousand years ago the mines of the Cassiterides (Sicily Islands) were producing this mineral, and many of the nearby mines of Cornwall remain on the "shipping list" at the present day. It is reasonable to suppose that there are many areas upon the North American continent where tin may, and probably does, exist in payable quantities. Let us take it that in many localities tin ore has been discovered, but that owing to its "unlikely" appearance it has not been identified as being a mineral of value. The fact that so little tin mining has been done upon this continent makes it apparent that comparatively few prospectors would be likely to recognize this mineral even should they come in contact with it. If these suggestions are worth anything, then we may take them as fairly good reasons why the discovery of tin ore has not been more frequent. To the unskilled eye the finer varieties of stream tin and "black sand" would appear very much alike, and frequently both minerals are associated in the same gravels. It is the purpose of this article to present to the reader a few of the simpler tests which may be applied to assist in the determination of cassiterite.

Let us suppose the prospector in the act of panning off a dish of gravel. He has thrown out the larger pebbles, and the material remaining in the pan is clean, washed gravel. Perhaps as his washing continues, and he rids the pan of the bulk of the lighter sand, he may find in the diminishing residue a number of "pretty stones," crystals of different colors and of varying degrees of transparency. These may be crystals of topaz, garnet, zircon, tourmaline, sapphire, etc., and if the prospector has any skill in applying the "hardness test," he will be able to identify these crystals fairly well by this means. If he is a judge of their other properties, so much the better; he can then make confirmatory tests. The sapphire will scratch a topaz and they will both scratch a quartz crystal, the sapphire quite easily, and the topaz less so. The other crystals will also scratch quartz if a sharp edge or point is used with a fairly heavy pressure. The presence in the pan of all or any of the above crystals are good indications of the possible presence of stream tin. As the panning off continues, black sands will perhaps

begin to appear. These black sands may consist of magnetite, ilmenite, wolframite, tourmaline or of stream tin alone, or associated with any or all of these minerals, some of them perhaps in the state of fine sand and some in pieces large enough to be easily picked out with the fingers. When the operator has reduced the material in his pan to a good concentrate clear of the lighter sand, the pan should be held over a fire and the contents dried. Then if a magnet will not attract any of the pieces or sand particles, there is no magnetic iron present. If the larger pieces which may remain in the pan show no disposition to be easily separated from the finer material they should be picked out and laid aside until some way can be found of testing them. If they are not attracted by the magnet they are likely to be tin ore or wolframite, but the latter mineral may easily be scratched by a quartz crystal. Stream tin varies in size. It may be found from the state of fine sand up to pieces of several pounds weight. It also occurs in many colors, the more common being black, brown, red and yellow. A sapphire will easily scratch the smooth surface of a pebble or crystal of stream tin, but a quartz crystal will only make a scratch when a heavy pressure is applied. Tin ore may, owing to its heaviness, be easily separated by panning, from almost any mineral with which it is likely to be associated. Where stream tin occurs it may be panned off in quantities varying from a few grains to as high as several pounds weight to the pan, according to the richness of the gravel. With a good body of tin bearing gravel and facilities for economical working, an average prospect of an ounce or less to the pan should give large profits.

Some attention has been already attracted to tin mining owing to the discoveries in Alaska; but, owing to the reasons stated, there is probably but a small proportion of miners and prospectors who have any practical knowledge of tin and tin mining. The prospecting season is once more approaching and if in the course of his explorations the prospector should come across an extremely hard and very heavy mineral, the appearance of which is unmetallic, and uninteresting, and unsuggestive of value, it might sometimes be worth his while to, at any rate, make sure that the substance in question is not cassiterite.

### The Tombstone District of Arizona.\*

Written for the MINING AND SCIENTIFIC PRESS.

One of the most picturesque mining districts of southeastern Arizona is that of Tombstone in Cochise county. The first mines of the district were discovered in 1878 by Ed. Scheffelin, his brother and Richard Gird, who were among the pioneers of Arizona, the latter being an engineer as well as a prospector and miner. There were eventually more than 1200 claims located in the district, but, as usual, the number of mines developed that proved to be really valuable was comparatively small. The most noted mines of the district were those of the Tombstone Mining Co., the Consolidated Contention Co., Grand Central, Head Center, Virginia, and several others of less value. The output of these mines reached many millions of dollars.

The geology of the district is simple, consisting of sedimentary beds of limestone, quartzite and shale, overlying a granitic formation which extends within 2 miles of the town. There are several beds of

Teaming Before the Advent of the Railroad, Tombstone, Arizona.

quartzite, limestone and other sedimentaries, which have for most part a low angle of dip—20° to 45°. These sediments are found intruded by eruptive rocks, dikes of which cut through the sedimentary beds in a north-south direction, though these intrusions are by no means regular in their distribution. The ore deposits are found in the limestone and shale, and also to some extent in the porphyry, specimens of eruptive rock from the Contention mine showing free gold. The quartzite, as it has been called, lying at the base of the series of sedimentary rocks, is of extremely fine grain, and has been thought to be of deep sea origin, but as it shows scarcely any sign of grain, so dense and compact is it, it seems more probable that it is really a silicification of previously existing limestone, or possibly a silicified shale, and not a true quartzite. In places it passes into the unaltered limestone, which gives color to the assumption that the horstone or novaculite is really a replacement of limestone by silica. This stratum of siliceous cherty rock was usually found to underlie the principal ore-bearing limestone of the region. The sedimentary beds of the district have been compressed into a series of folds, along which the mineralization has chiefly taken place.

The most pronounced fissure of the district passes through the Grand Central and Contention mines, and is thus described by Wm. P. Blake:

The ores of the district are both milling and smelting. Black oxide of manganese was very abundant in some of the ore shoots. Some of the so-called milling ore contained over 70% manganese oxide, and only 18% to 25% silica, and in the smelting ore samples ran as high as 47% manganese and as low as 26% silica. These ores gave much difficulty in their treatment.

Notwithstanding the difficulties encountered, much of the ore was worked to over 80% of its value. As depth was reached, water began to show in the mine workings. This increased with more extensive and deeper development until there was no longer a profit in mining under existing conditions. The mines were finally closed down and remained practically idle for years. E. B. Gage conceived the idea of consolidating the principal mines of the district, and unwatering the flooded levels. The old workings were mostly useless, the shafts caved and timber decayed, but although the scheme involved the expenditure of a large sum, it was undertaken and successfully carried out. In 1901 a four-compartment shaft was be-

gun on the Contention mine, in size 10 by 24 feet (7 by 22 feet inside timbers). It is solidly timbered with Oregon spruce. An elaborate pumping plant with a capacity of 2,500,000 gallons was installed when the water level was reached, and the development of these great mines is progressing.

Since the former closing down of the mines, commercial and other conditions have changed greatly for the better. A railroad is now within a few miles of Tombstone, pumping machinery is more efficient and the cost of raising water is less than formerly. Mining methods have improved and the great advance in metallurgical science will also aid in making the mines of Tombstone district once more profitable. The accompanying illustrations of Tombstone and its mines are published through courtesy of the Bisbee Daily Review.

The principal claims were located in a north-south direction upon the somewhat obscure croppings of a dike of diorite porphyry carrying ore in, through and alongside of it. This location was made by White and Parsons. The croppings were not remarkably well defined, consisting of the porphyry and a confused mixture of porphyry, chert and quartz, with masses of porous quartzite alongside, none of these rocks rising high above the soil. There was, however, a considerable discoloration of the soil by iron rust along the line, and a little digging revealed good ore near the surface. The harder parts of the dikes were the most prominent, and its direction governed the direction of location of the claim. This dike varies in width from a few feet to 50 feet or 70 feet, and dips to the westward at an angle of from 55° to 65°. It cuts indiscriminately through shales, quartzites and limestones and is evidently of igneous origin. The contact, however, with the abutting edges of the disrupted beds is not always marked by any great change in their appearance or composition, though in places there is obscure metamorphism, impregnations of silica and some modifications of structure. The dike itself has a distinct vertical lamination or structure through most of its substance and is more or less penetrated by veinlets of quartz. In some portions it is highly crystalline and nearly barren, and in others consists chiefly of a feldspathic base,

Pump in Contention Mine, Tombstone, Arizona.

\*See illustrations on front page.

in which the feldspar crystals are obscure. It passes into a felsite, which, in the decomposed portions of the dike and when slaty in structure, might be mistaken for the partly decayed shales or quartzites. Large portions of the dike are so penetrated by quartz as to consist largely of it, and might be called quartz, although close examination will show the presence of feldspar.

A section across the vein of the Head Center mine, on the Contention lode, shows vertical fissures, and a general distribution of quartz in vertical seams. In general, quartz crystals are wanting. Between the vertical streaks of quartz is a filling of feldspar.

There is also a considerable amount of mineralization of the dike by iron pyrites disseminated irregularly in its substance in cubical crystals, most of which have dissolved out and left the cavities only to indicate their former presence, making in some places a spongy mass of porphyry or of quartz. Although the mine has been worked to a depth of 600 feet, and there are some 12 to 15 miles of drifts, levels and winzes in the Contention and adjoining mines, the undecomposed ores below the water line have not been reached and mined, and all the ores above are in the decomposed and oxidized condition common to surface ores. A large part of the ore is highly charged with red oxide of iron to such an extent that the clothing of the miners becomes saturated with the rouge-like powder and the tailings at the mill are blood red.

There has been an extensive decomposition of the porphyry, especially along the upper 300 feet of the dike, resulting in the formation of quantities of white clay, kaolin, sometimes perfectly snow-white and pure, but generally more or less mixed with red oxide of iron. This kaolinization extends in places to the adjoining shales, and there are some white, clay-like, interstratified beds which may on further examination be found to be altered felsitic offshoots from the dike. It is not yet possible to say what the exact nature of the ore below the water level will be found to be. The only metallic contents so far found, with the exception of the pyrites and some galenite and lead carbonate, are gold and silver in a comparatively free state, part of the gold, if not all, being free, and the silver occurring chiefly as chloride, or horn silver (with probably some iodide) in crusts and films, also occurring in minute crystals upon cleavage surfaces. The average value of silver and gold in the ores was about \$70 per ton. The gold in later years increased from 20% to 25% of the value of the product, the rest being silver.

**GOLD IN PORPHYRY.**—One interesting fact is the occurrence of free metallic gold, together with chloride of silver, in the midst of the porphyritic rock, at a distance of many feet from the portions of the porphyry carrying quartz in veins and disseminated. This gold is found chiefly in a portion of the rock apparently dioritic, containing finely disseminated hornblende. In decomposing, this porphyry becomes steatitic and in places appears to be changing to serpentine. The gold is found in thin sub-crystalline flakes and scales, chiefly in and along thin seams and cracks in the mass of the rock, as if it had been infiltrated and deposited from solution. This is probably the fact, and the magnesian nature of the rock has no doubt exerted an important influence in its deposition. Free gold is also found in quartz in the usual manner of association; but even in such specimens the crystalline feldspar of the dike is found.

**METALLIZATION OF THE DIKE.**—The time and manner of metallization of the dike may be considered as open questions, for a solution of which we must wait until the mining extends below the permanent water level of the formation. It seems most probable that the rock at the time of its intrusion was pyritous, and the strata adjoining it no doubt were. It is not impossible that there may have been a concentration of the precious metals in the dike from the surrounding beds, the result of the decay and change of the pyrites diffused in the strata. On the other hand, we may suppose that the dike has been the source of the silver and gold we find in and about it.

In either case the vertical laminated or stratiform structure parallel with the walls has been an important factor in the distribution of the metals and in the changes and modifications of the original condition of the dike. We may readily conceive of such vertical planes of structure affording planes or lines of least resistance to vertical movements, while the abutting ends of the strata, in contact with the walls of the dike, would offer great resistance by friction. The condition of the dike along a great part of its course seems to sustain and verify this hypothesis. There has evidently been considerable movement of parts of the dike upon itself, resulting in the formation of heavy clay seams and brecciated layers of porphyry and quartz, sometimes occupying a medial position along the dike, sometimes on one side or the other, and again along the line of contact with the country rocks. Such seams and brecciated ground are sometimes wanting and the structure and condition of the dike remain unchanged.

The whole of the dike with the adjoining strata have been subjected to extensive movements and displacements, shown not only by breaks of continuity, but by the brecciated cross courses and seams traversing both the igneous and stratified formations.

One of these faults, resulting in a throw of the northern portion of the Contention lode, 150 feet to the west and partly outside of the west side line of the claim, which led to expensive litigation. The faulting seam or break has been drifted upon between the two ends of the disjointed dike. It consists of a heavy breccia of fragments of the adjoining strata, together with a strong clay wall, marking the plane of greatest movement and slip. Its direction is southwest and northeast.

In addition to the lateral movement there have been extensive vertical displacements, and it is probable that the lateral shifting may be referred to them. It would be premature to attempt an exact description of the numerous faults and mechanical changes to which the dike has been subjected.

The movement appears to have been from the west eastward and downwards, the top of the dike being carried off in successive blocks by the sliding of masses of the stratified formations partly upon the planes of deposition of the beds—these dipping eastward and affording surfaces of easy movement—and partly upon steeper planes of fracture generally dipping eastward, as shown in the outline sketch section, which may be taken as typical.

This disruption of the dike, with its attendant fracturing and brecciation of the country rock, accompanied by the movement of the dike upon itself, and the formation of heavy clay seams, has provided favorable places for the accumulation of ore. It is generally found in the softer and most broken portions of the dike, coincident, no doubt, with the regions of greatest original metallization and subsequent movement, attended by clay seams. Such clay seams, with the accompanying ore, have by some been considered as marking the limits of a second or subsequently formed vein; following the dike and independent of it. This theory, formed under the inspiration of the necessity of narrowing down the vein and throwing it as far west as possible, in order to secure a greater length of it upon the Head Center ground, would be more defensible, if in the steeper any vein structure referable to a later deposition could be found. Instead of the fragments of broken porphyry, shale and quartz being cemented together by quartz, they are loosely aggregated and show clearly that the formation is due to mechanical force and attrition. The clay seams are also not certain boundaries of the ore; it occurs on both sides of clay seams. The clay can not, therefore, be taken as separating ore from waste. The seams, moreover, are not continuous, but give out, and in some parts of the dike are absent.

**BEDDED ORE DEPOSITS.**—These also are associated with dikes and vertical fissures nearly parallel with the Contention lode. One of the longest and best defined is the West Side lode, which may be traced for about 2 miles, until it passes into the underlying granite. Its northern prolongation appears to cut across the Toughnut claim and to connect with the vertical fissure and quartz croppings at the Discovery shaft on the Goodenough.

A second line of fissure cuts across the anticlinal line of the formations at the open cut on the Toughnut and crosses the whole breadth of the Goodenough into the Way-Up claim beyond. This has been followed on ore from the open cut to the Way-Up and is connected with the chief lateral bedded deposits. A lode has also been followed in the same general direction from the claim called the Defence, across the Toughnut into the Goodenough. This lode is marked by the heavy croppings of quartz and flinty boulders lying above the limestone on the surface.

In the fissure extending into the Way-Up claim the ore was found in layers and bunches following the plane of the vein, extending upwards and downwards along its course in nearly vertical shoots or ore bodies, but breaking off into the adjoining strata in flat bed-like layers, particularly when the vein intersects the lower limestone resting on the novaculite beds. These bedded offshoots from the vein are often of considerable lateral extent, following the planes of stratification on either side.

In extent the bedded masses of the Goodenough and Toughnut claims have been much greater than the ore bodies of the vertical fissures, and it may be said that the greater part of the production has been from the beds or flats. They extend irregularly between the two fissures a distance of about 400 feet, measured diagonally along the dip. It is noteworthy that they follow the stratification and then suddenly break across it vertically, following a crack or break of the bedding, and then expand again horizontally for some distance to another, dropping down by a series of steps from one layer to another in and between the limestones.

The ores found in these bedded deposits in the limestones are much more plumbiferous than the ore of the feldspathic dikes. Galenite, blende and iron pyrites are abundant in masses, which, within the reach of oxidizing agencies, are largely converted into oxides and carbonates.

THE efficiency of a steam boiler does not depend upon the type of a boiler nearly so much as upon a proper circulation of water and the products of combustion. Boilers of varying types give approximately similar results when all operating conditions are equally favorable.

## THE PROSPECTOR.

There are many who desire to equip themselves and make a prospecting trip this coming spring and summer, and the question has been asked as to the opportunities in Nevada and Arizona, also as to Alaska. It is with some hesitancy that this department makes any suggestion as to a suitable field for the prospector, for several reasons. Among them are the climatic conditions obtaining in each of the three sections mentioned. While undoubtedly at this time any prospect of promise at all in southern Nevada would sell or attract capital more quickly and easily than one in almost any other section of the United States, the hardships, privations and dangers which beset the prospector in that region, whether he be a "tenderfoot" or not, are a sufficient consideration to deserve earnest attention and not to be lightly passed over. The scarcity of water in that vast desert region, the intense heat of summer, the difficulty of getting supplies for men and animals and dangers from reptiles are among the drawbacks to prospecting in southern Nevada, and the same applies to a large portion of western and southern Arizona. However, there are hundreds of miles of desert and mountain still practically unknown between Virginia City, Nev., and Cananea, Mexico. A glance at a map of Nevada and Arizona will show that along a line connecting Virginia City and Cananea, and situated within a very few miles on one side or the other of it, are the following towns, camps and mines: Dayton, Hawthorne, Candelaria, Silver Peak, Tonopah (25 miles northeast), Goldfield, Lida (about 20 miles southwest), Crater (Good Spring and Searchlight are only a few miles from the line, on the west), El Dorado Canyon, Chloride, Mineral Park, Cerbat and Stockton Hill, in Mohave county, Ariz. The San Francisco district, where are located the Gold Roads and other important mines, is but a few miles to the westward of the line. Continuing southward, the line passes through Hillside and Santa Maria districts, Wickenburg, Harqua Hala, Congress, Vulture, Florence, Tombstone and Bisbee, Ariz., and Cananea, Mexico. It may be argued that this is merely a coincidence; but the fact remains that along this line are some of the most noted mines and mining districts of the Southwest. It is true there are scores of good mines and noted districts at long distances away on either side, as, for instance, Jerome and the district about Prescott and southerly from there. And in southern Nevada there are numerous rich mines and districts far removed from this imaginary line. Still the fact remains that good mines have been developed along this particular line, and it is improbable that all have been found. The desert region between Goldfield and El Dorado canyon appears to offer the greatest possibilities at this time, for the reason that it has received less careful attention than those sections more easy of approach and where water is more readily obtainable. In the direction of the line here referred to there is a large area in Arizona, in Yavapai county, covered by a floor of basalt that is from 200 to 1200 feet deep, and it is only where erosion has cut down to the older underlying rocks that prospecting can be carried on. As to Alaska, it is probable that the tributaries on the west side of the Yukon river in American territory offer as good inducements and advantages as any other for gold, particularly when capital can be had for development. The indications are that there will be a considerable development of copper in Alaska along the islands of the coast and in the interior also.

The ore from the Empire mines, Grass Valley, Cal., contains chiefly zincblende, a small amount of chalcophyllite, a smaller amount of pyrite and a bright, scaly, metallic mineral having the luster of bright galena, but which is semi-sectile and is probably nagayagite, a sulpho-telluride of lead and gold, and, according to Dana, containing also about 7% antimony. The mineral occurs in such small amounts that tests are difficult to make, but it seems to answer to all the properties ascribed to nagayagite. Free gold is also present in the specimen. The only gangue mineral observed is quartz. This visible gold is for most part closely associated with the blende.

The mineral from Oro Fino, Siskiyou county, Cal., carrying gold is baryta (barium sulphate), often called heavy spar. A small amount of strontium sulphate (celestite) is also present. This is a combination seldom gold bearing. The honeycombed structure is due to the removal of some soluble constituent.

There are a great many kinds of copper ore, but the ores producing the greatest amount of copper are the low-grade chalcophyllite ores of many mining districts all over the world. Copper glance and bornite are also mined extensively, but in much less amount than chalcophyllite. The oxidized ores—malachite, azurite and the black and red oxides—are of comparatively little importance, though they constitute the principal source of the metal in some districts.

# Mining and Metallurgical Patents.

PATENTS ISSUED MARCH 14, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

ELECTRIC HEATER FOR OIL OR GAS WELLS.—No. 784,454; F. B. Waring, Lima, Ohio.

Heater for oil wells comprising pair of supports having plurality of openings, plurality of tubes having ends extending in openings and hermetically connected to supports, heating devices extending through tubes and out of contact therewith, means carried by supports for centering heating devices within tubes, binding posts carried by one of supports and connected with heating devices, and leading-in wires connected to binding posts.

WELL DRILLING MECHANISM.—No. 784,571; J. C. Knupp and J. G. Greene, Warren, Pa.

In device of class described, driven shaft carrying band wheel and tug wheel, shaft having crank, walking beam, pitman connecting walking beam with crank, sand reel carrying shaft, permanent support for one end of shaft, box forming bearing for other end of shaft, box having upward and downward extending trunnions, longitudinally slidable frame having bearings for trunnions, friction wheel upon sand reel shaft adapted to engage band wheel, brake block adapted to engage friction wheel, and means for manipulating slidable frame.

METHOD OF EXTRACTING METALS FROM ORE BY ELECTRICITY.—No. 784,885; E. L. Priest, Oakland, Cal.

Method of extracting metals from ores by electricity, consisting in forming body of comminuted ore

into coherent mass, associating electric conductor with same, and positioning mass with its conductor in contact with liquid electrode and passing electric current through same to form arc therebetween.

CYANIDE AGITATOR.—No. 784,598; E. Stevens, Leadville, Colo.

Combination of containing vessel provided with frusto-conical portion, basin engaging frusto-conical portion, basin being provided with bearing, tubular member disposed within containing vessel, and revoluble shaft provided with carrier thread disposed within tubular member, revoluble shaft being provided with journal engaging bearing within basin.

METHOD OF SMELTING ORE.—No. 784,651; R. Bagaley, Pittsburg, Pa.

Method of producing matte which consists in forming molten bath of matte and charging body of ore in such limited quantity that it will float with bottom above bottom of furnace, and blowing air into bath.

MEANS FOR COUPLING MOTORS TO ROCK DRILLS.—No. 784,757; J. H. Redfield, Denver, Colo.

Combination with guide shell, of rock drill or similar machine, of electric motor yieldingly suspended therefrom, and operative connection between motor

and drill, including tubular telescoping parts whereby coupling is extensible to compensate for back-and-forth movement of drill body on guide shell.

DUMPING BUCKET.—No. 784,815; G. L. Stuebner, Flushing, N. Y.

In bucket combination of hinge, bottom swinging from hinge and extending on opposite sides thereof, pocket in bucket, counterweight guided in pocket with its lower face arranged to bear against one of ends of swinging bottom, latch hinged to bucket and arranged to bear against top face of counterweight.

DETACHABLE TOOL HANDLE.—No. 784,772; W. Ashert, Des Moines, Ia.

Combination with tool having handle eye and also having notches adjacent to upper end of handle eye, of cross piece resting in notches and formed with central opening, handle socket having body portion introduced into handle eye, body portion formed with notch at upper end to receive cross piece and screw-threaded rod passed through cross piece and seated in socket.

MECHANISM FOR HAULING AND CONTROLLING OF CARS.—No. 784,898; J. G. Scott, Girardville, Pa.

In mechanism for hauling and controlling cars, track comprising single pair of rails for car and "barney," rails being provided with switch sections nominally open when "barney" is on main track, and adapted to be positively closed by movement of "barney" into its pit.

APPARATUS FOR SEPARATING AND CONCENTRATING MINERALS.—No. 784,999; G. A. Goyder and E. Laugh-ton, Adelaide, South Australia, Australia.

Apparatus for separating minerals and extracting some of them as concentrates consisting of vessel adapted to contain solution, floor of such vessel being partly horizontal and partly inclined and provided with means for heating solution, feeding hopper extending across one end of vessel adapted to feed ore or minerals in finely divided state, series of transverse rod rakes, and means for moving them at regulated speed along bottom of vessel from feed to discharge end, inclined deflectors along and above bottom of separating portion of vessel, trough receptacles arranged parallel with deflectors and at such distance from bottom of vessel as to enable gas raised particles of mineral to be deflected, guided, deposited and collected therein, sloping extensions of troughs and angular rakes for discharging concentrates from troughs through sloping extension of vessel.

## MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

### ALASKA.

The Mansfield G. M. Co. has resumed work on McGinnis creek, near Juneau. G. W. Otterson is manager.

Fairbanks, one of the newest centers of the northern rush, had 10,000 people last January, and expects to double that next year. The prices of some of the necessities of life there last January were as follows: Flour, per cwt, \$13; meat (fresh) per pound, 60c to 75c; pork, 50c; potatoes, 20c; dried potatoes, 60c; corn meal, 20c; rolled oats, 20c; rice, 20c; beans, 20c; sugar, 50c; dried fruits, 50c; lard, 33c; butter, \$1; canned vegetables, per can, 50c; condensed milk, for three cans, \$1.25; coal oil, per 5-gallon can, \$8.

It is reported that Fairbanks and Chena have lost their floating population in a stampede to the Little Delta district, 100 miles above Fairbanks, in Tanana valley. New strikes there are making a better showing than at any creek in the Fairbanks district. At Tenderfoot creek coarse gold running 11 cents to the pan has been found at a depth of 3 feet; at Little Delta it averages 10 cents, and along Gerstle river 8 cents. Three rival townsites have been staked, Roosevelt City having a population of 300. Tenderfoot will be another town. Not since the discovery of gold on Pedro creek, two years ago, has there been so much excitement in Alaska.

### ARIZONA.

(Special Correspondence).—The Twenty-third Arizona Legislature has adjourned, and all the bills affecting the mining industry failed of passage. The hullion tax bill, the bill providing for a mining inspector and the bill prohibiting the use of any form of evidences of indebtedness in place of cash in payment of wages all were safely side-tracked and pigeon-holed. Some of the legislation aimed at Arizona mines was meritorious, but the mining interests exerted every effort to prevent its passage and was powerful enough to be successful. The hullion tax law was the measure of greatest importance, framed with the idea that the big producing mines of the Territory were not contributing their share to Territorial funds. Affecting as it would only the producers, the law if enacted would not have had the deterrent effect on the mining industry, which, it was argued, it would have and would have added greatly to the revenues of the Territory.

Phoenix, March 20.

#### Cochise County.

(Special Correspondence).—C. B. James, general manager for the Cochise Con. Co., will purchase machinery for their concentrating plant to be built on their property near Paradise. A large quantity of ore is stacked ready for concentration. It is expected the concentrator will be ready for operation about July 1.

Paradise, March 20.

(Special Correspondence).—Contracts representing \$300,000 have been let by the Copper Queen Co. at Bisbee for the development of the Douglas smelter. Four engines to run the new blowers were ordered, each of which will have a capacity of 12,000 feet of air a minute. A contract was let for an air compressor with a capacity of 3000 cubic feet. A blower was ordered for a converter, to have a capacity of 12,000 cubic feet of air a minute. The production of hullion copper at the reduction plant of the Copper Queen at Bisbee for the month of February broke the record of production for the Southwest for any one month since the copper has been mined, being 7,012,000 pounds.

Bisbee, March 20.

#### Mohave County.

(Special Correspondence).—P. H. Smith, A. H. Smith and M. A. Sawyer have located a deposit of wolfram ore on the east side of the Cerbat range, 6 miles north of Kingman. The ore occurs in massive dykes of feldspar. Kingman, March 20.

The Mohave mine, near Vivian, has put in a hoisting plant and is sinking a shaft.—It is understood that A. J. Pickrell will develop the Maguire mines, south of Kingman.—The mine operators of Gold Road and surrounding camps are reported to have formed a mine operators' association similar to that at Cripple Creek, Colo.

#### Yavapai County.

(Special Correspondence).—The Yaeger Canyon copper mine in the Black Hills district, near Prescott, has sunk the main shaft down to the 800-foot level, and a drift has been run 600 feet along the foot wall of the ledge. The recent rains have made hauling difficult and the company's ore bins are overflowing. The company has a hoisting engine of sufficient capacity to work to the 1500-foot level. R. E. Sloan is manager. The formation is diorite and slate, showing three principal ore bodies occurring as fissures in diorite.

Prescott, March 20.

### CALIFORNIA.

#### Amador County.

The shaft of the Climax mine, 5 miles east of Jackson, is down 200 feet. The ledge matter has widened to 6½ feet. Drifting will begin 100 feet below the upper levels. A 10-stamp mill will be built to take the place of the 2-stamp mill. The company will employ between twenty and thirty men when the new mill is put into operation. P. B. Aiken is superintendent.—At the Zella mill, near Jackson, forty stamps are dropping. New levels are being opened up at 1450 and 1550.—The Central Eureka mine at Sutter Creek produced in January 4800 tons of ore valued at \$29,200. The ore averaged \$6 to \$8 a ton. The main shoot has been sunk on an incline to a depth

of 2380 feet, all in ore from the 1000-foot level. A ten-years' contract has been let for electrical power to run the 40-stamp mill and rock breaker, and later on it is expected to operate the hoist by the same power.—The drift being run from the Lincoln shaft to the Mahoney mine at Sutter Creek is in 650 feet.

#### Butte County.

H. H. Yard and W. P. Hammon of Oroville are making arrangements to work auriferous gravels in Butte and Plumas counties by means of steam shovels which will load the dirt and gravel in flat cars, by which it will be carried to convenient sluiceways, where it will be unloaded by water from hydraulic nozzles. Preliminary estimates of cost place digging at 5 cents per cubic yard, hauling 1 cent per cubic yard and unloading and sluicing at 3 cents per cubic yard.

#### Del Norte County.

The Klamath River Dredge M. & D. Co. intends working 2100 acres of mineral land extending from mouth of Klamath river inland, 22 miles, in Del Norte and Humboldt counties. The principal place of business is at Dunsuivre. J. B. Dougherty is president and D. O. Tupper secretary and treasurer.

#### Calaveras County.

Shaft sinking has been commenced at the Port Arthur mine, near Altaville, by Superintendent Lewis Lane.—The shaft of the San Andreas Blue Gravel Co. has been enlarged and retimbered to a depth of 75 feet and is now being continued to bedrock by Superintendent G. A. Stewart of San Andreas.—The Benson mine, 4 miles west of San Andreas, has put in an engine and air compressor.

#### Lassen County.

(Special Correspondence).—A rich vein has been struck on the 300 level of the Lassen M. Co.'s mine on Hayden Hill. The vein is from 2 or 3 inches to a foot in width and runs \$250 per ton gold. There are two principal fissures in this mine crossing each other at an angle of about 30° to 40°. There seems to have been some displacement at the intersection, resulting in the brecciation of a considerable mass of rock, which has been since altered and much decomposed, with the infiltration of silica and gold, a large valuable ore shoot being formed, which has been extracted. In the progress of development it has been observed that pockets of gold formed on and near the walls of this ore chamber where several seams or veins entered it from the surrounding barren walls. Several of these seams have been drifted upon and in almost every instance the seams have led to rich deposits or veins of gold-bearing rock. The recent strike is one of these occurrences, but has the appearance of being more permanent and valuable than the most of those formed heretofore.

Hayden Hill, March 18.

#### Mariposa County.

The Champion mine, 1 mile north of Coulterville, has been hounded to C. E. Van Meter and the work of unwatering has been finished. The shaft is 200 feet deep.—The Columbus Con. G. M. Co. has completed surveys and maps of their property, near Coulterville, preparatory to commencing work on an extensive scale.—At the Mt. Gains mine, east of Hornitos, the old dump is being milled with a Huntington mill. F. E. Long is the general manager.—W. H. Cavin is running the Organita mill on ore from the Grimshaw mine, near Mariposa. At the Grimshaw ten men are at work. The shaft is down 200 feet.

#### Placer County.

It is reported that P. S. Lozano of Ophir intends putting machine drills on the Bellevue mine.

#### San Francisco County.

The auxiliary electric power plant which is intended to supply power for the operation of the United Railroads in the event of any interruption in the long-distance transmission lines of the California Gas & Electric Corporation, after that company enters upon its power contract with the railway corporation, is being built on the bay shore at South San Francisco. According to the company's plans for the big power plant, there will be installed at the South San Francisco works the largest gas engines ever constructed in the United States. There will be three of these engines, each of 5333 H. P., or a total of 16,000 H. P., as against 12,000 H. P. now developed at the power stations of the United Railroads. These engines will each be directly connected to a three-phase, 4000 kilowatt, 25-cycle alternator. There will also be two motor-generator frequency changers, having an output of 4000 kilowatts each. The main building of the power station will be 200 feet in length by 90 feet in width, which will accommodate three engines, motor generators and exciter sets, with an addition 36x80 feet in size, in which will be installed a storage battery, high-tension transformers, pumping apparatus and the general operating switchboard of the station. Outside of the main building there will be storage tanks, cooling tanks and other apparatus. In connection with the gas engine station there will be an oil gas plant for the manufacture of oil gas and a storage gas holder of 1,000,000 cubic feet capacity. The construction of the power plant, buildings and gas engine units, together with the high-potential transmission lines connecting the power station with the seven water power plants of the company, will be in charge of F. G. Baum, transmission engineer of the company. The erection of the gas plants and their equipment will be in charge of E. C. Jones, gas engineer of the company.

#### Shasta County.

The Rising Star mine of the Bully Hill Copper M. & S. Co. at Winthrop is supplying the furnace with 125 tons daily. The Northern Light, adjoining the Rising Star, is bonded to the Bully Hill Co. and is being prospected by drifts running from the Rising Star. In the Bully Hill claim the shaft is down 870 feet, where a station large enough for a hoist is being cut. J. B. Keating is superintendent, H. C. Anchor assistant superintendent Rising Star mine, M. Thomas assistant superintendent Bully Hill mine, H. Hanley engineer and surveyor, Ed Wilson assayer, Geo. Nagle and Geo. Krause smelter foremen. Bully Hill rises 1200 feet above the surrounding country and is composed chiefly of rhy-

olite, with three mineral veins striking north and south. The ore occurs in shear zones in rhyolite and metabasite dikes, all of superficially slaty structure, the lenses having a clay gouge of 1 to 30 feet on one or both walls. The main ore bodies below the zone of secondary enrichment carry chalcopryrite associated with pyrite, also hornite and chalcocite, with occasional carbonate and oxide ores and native copper. It is expected that the 300-ton smelter will be running full capacity by July. The smelter is 39x100 feet in size, with a 90-foot stack. The reduction plant is terraced, handling all material by gravity, and has roast stalls in series, with two McDougall caking furnaces and two 42x120-inch blast furnaces, making matte of 35% to 50% tenor, which is taken in ladles by a 20-ton electric traveling crane to the conversion department, which has two stands of converters, turning out 98% blister copper, which is shipped to New Jersey for refining.

Following the announcement of the granting by the United States Circuit Court of a permanent injunction, enjoining the Mountain Copper Co. from allowing the fumes to escape from its smelter at Keswick to the destruction of vegetation, the Mountain Copper Co. has notified those mines which have been furnishing siliceous ores for fluxing purposes that no more ore would be received. Several of the mines affected are contemplating putting up stamp mills to treat the ores at the mines. The Crown Deep mines on the Shasta road, west of Redding, J. Hulme, managing owner, and the Reid mine in Old Diggings, near Redding, under bond to J. Sallee of San Francisco and D. B. Hunt of Redding, are among those affected.

It is reported that Delamar's Bully Hill mine and smelter have been sold to the General Electric Co. of Schenectady, N. Y., for \$1,000,000. Anticipating the deal, H. A. Cohen, former consulting engineer for Delamar, filed an attachment for \$50,000 on the land embraced in the Delamar holdings. The Bully Hill property includes seventeen lode claims and one placer claim, all patented, aggregating 213 acres. The ore lies in lenses connected by narrow seams of ore. Limestone and ironstone for fluxing are obtained on the McCloud river, about 6 miles distant. Sufficient silica is obtained from the mine.

#### Siskiyou County.

At the New York quartz mine at Indian creek, 30 men are at work. The ledge has been developed to a depth of 900 feet and the 10-stamp mill is in operation constantly, being run by electric power from the Siskiyou Electric Power Co. J. B. Scott is superintendent.—A. C. Brokaw is crushing the ore from the Golden Eagle quartz mine at Indian creek, with a steam power stamp mill, which he expects to enlarge and run by electricity when the ledge is more thoroughly developed.—Baker & Co. have a ledge on Indian creek, which they are developing with a small steam power mill. Bryant & Co. have completed a 10-stamp mill at Deadwood. Perry Elmore has leased his mine on north fork of Humbug to Louis A. St. John and A. H. Lamm for Eastern capitalists, with option of purchasing.—The Yreka Journal says that the project of dredging Oro Fino creek is likely to prove a paying enterprise, as it has always paid by hydraulicking the banks.—Men are working the Gardner & Eastlick hydraulic mine at Oro Fino. They have plenty of water for the elevators and are running night and day.

#### Trinity County.

A storm in Trinity county carried out the ditch furnishing the Fairview mine at Minersville with water, and milling has been suspended.

#### Tuolumne County.

Superintendent M. D. Kelly has started twenty stamps at the Jumper mill at Stent.—A steam hoist has been put on the Omega, near Jamestown, and sinking is being continued in the shaft. Machine drills are to be used. C. W. Ayers is superintendent.—Electric power is to be used at the Clio mine, near Jacksonville.

C. F. Brownlee has deeded to W. P. Huston of Angels a half interest in the Wickham quartz mine, near Tutletown.—A rich shoot of ore has been struck at the App mine at Quartz. In the mill 60 stamps are dropping.—It is reported the Platt & Gilson vein has been struck at the Soulsby mine at Soulsbyville.

#### Yuba County.

Roberts & Brown are putting up a 5-stamp mill at Brown's Valley, to work ore from the dumps.—Stephens & Whittier are taking out ore from the Last Chance and will haul it to the new mill at Brown's Valley.

### COLORADO.

(Special Correspondence).—As the long continued governorship contest has at last been settled, it is earnestly hoped that the mining and business interests of the State will continue to improve. From information gathered from the manufacturers and sellers of mining machinery and supplies, the inquiries for machinery of different kinds and prices thereon have been heavy the past month or two, and they are of the opinion that the orders will now commence to come in. The Governor, Jesse F. McDonald, is a mining operator of Leadville. Indications point to a large number of new mills going up this coming season. Last year mill building in Colorado was at low ebb. A large number are now under construction and plans are being made for several others.

Denver, March 20.

#### Clear Creek County

Work has been resumed on the American Sisters mine, near Georgetown, which has been idle since August 28, 1893, when the mine buildings and machinery were destroyed by fire. Machinery is being put over the Headlight shaft. The shaft is now 160 feet deep and will be sunk another 150 feet.

The Rockford tunnel of the Colorado D. & I. Co. being driven on Clear Creek, 2 miles above Idaho Springs, to open up the Turkey Creek claims, is in 800 feet. The Rockford tunnel is 5x7 in the clear and has cut four veins. Machine drills and a 4-drill compressor are to be put in, to drive 3000 feet farther. Arrangements have been made to develop the Centurion and Golden Hills mines through the tunnel and transport ores that are now being hoisted.

OFFICIAL ESTIMATE OF THE VALUE OF COLORADO'S MINERAL PRODUCTION BY COUNTIES FOR 1904.

COUNTY.	Gold.	Silver.	Lead.	Copper.	Zinc.	Total.

NOTE.—In the above table the calculation is on the average market price of the metals for the year: Gold, \$20.37; Silver, \$0.5723; Lead, \$0.913; Copper, \$0.1223; Zinc, \$0.954. Zinc is figured on actual spelter recovered.

Denver County.

Directors of the American Mining Congress, in session at Denver, have decided to erect a mining temple in Denver to be used as headquarters, and also to gather together a permanent mining exhibit. The following directors were present: Thomas Ewing of San Francisco, Cal.; G. W. E. Dorsey of Fremont, Neb.; E. Buckley of Rolla, Mo., and A. W. Gifford of El Paso, Tex.

Fremont County.

W. H. Murray of Parkdale has sold the Isabella mine in Smith gulch, near Canon City, to Boden and Haskins of Leadville, for \$20,000. The mine will be operated on an extensive scale, arrangements having been made by the new owners to sink a 300-foot shaft and begin the work of production.

Gilpin County.

It is reported that the California mine, near Nevada, is to be reopened. The main shaft is down 232 feet and is said to be the deepest gold mine shaft in Colorado.

F. C. Young, manager of the Gunnell M. Co. of Central City, says that the company is operating all their mills on Clear creek, and that by summer they intend to have the shafthouse of the Gunnell mine in Eureka gulch, which was destroyed by fire last summer, rebuilt, and active operations on the property will then be resumed. A new plant of machinery will be installed to replace that which was also damaged by the fire.

The Caledonia mine in Lake district, near Central City, owned by the New National Tunnel M. & M. Co., has been started up under the management of G. W. Adams. The property is equipped with a gasoline hoisting plant and the shaft has been timbered and put in good condition from top to bottom, a depth of 400 feet. Sinking operations have been carried on to carry the shaft down 200 feet farther. Drifting is being carried on in the 300 west and in the east and west 400-foot levels, stoping being carried on in the 400-foot west level. Shipments are made to the Rocky Mountain concentrating works in Black Hawk. The tunnel is in 2100 feet. Machine drills may be put in.—John Eilmann and F. Wenzel, both of Central City, have struck high-grade ore in the Susan Mary mine in Lake gulch.—The Register-Call reports that drifting is being carried on in the 400 and 500-foot west levels of the O'Neill mine on Bortail hill, operated by the Ontario-Colorado M. Co., with H. C. Eastman as manager. The 500-foot level is being extended to get under the large ore body, but Superintendent H. Bowden says it will be necessary to drift 180 feet farther in this level before they can get under the ore body from which they are taking out shipping ores in the 400-foot level. Rand air drills are being used in these two levels and good headway is being made.—A 3x4x12 Jeaneville pump, size 6, is being put in by the Boston-Occidental M. Co. at American City, in the Pine Creek district.—Central City parties are working the Dump mine on Bortail hill under a lease and bond from the Arrighi estate, and they are keeping up both development work and extracting a good grade of ores. The shaft has been sunk 300 feet. Drifting is being done in the east and west levels at a depth of 280 feet. They are at present operating with a whim for hoisting, but may put in a small plant of machinery for deeper operations.—It is reported that active operations are soon to be resumed on the Chemung-Belmont, which will include the deepening of that shaft. The property is owned by Black Hawk people and is under lease and bond to the Central Bonding & Leasing Co. The present shaft is down 700 feet.—The Puzzle mine in Gregory district is being operated under a lease by W. Martin of Central City.—Superintendent Kirk will sink 100 feet from the 400-foot level of the Castleton mine on Pewabic mountain, near Central City, as soon as the new hoisting plant is completed.

Gunnison County.

(Special Correspondence).—The Continental gold mine at Vulcan is to put in a mill. J. Schreier, Jr., an owner, has returned to after a two months' visit at the mines. D. C. Tobin is superintendent.

Vulcan, March 21.

The Baalbeck M. Co. has its tunnel on its properties below Hancock in 900 feet. A drift on the big fault encountered for 100 feet caught the ore shoot again and the company expects to soon be shipping ore. T. B. Crawford of Denver is interested.—T. C. Clayton of Denver will soon commence a tunnel into Brittle Silver mountain, east of Sberrod.

At Pitkin Linn, Langill & Smith are drifting and sinking on the Sultana.—The incline shaft of the Cortland mine, near Pitkin, is down over 230 feet, with a vertical depth of 185 feet, in the bottom of which is showing a 10-inch vein of high grade silver ore.—The Gold Links tunnel is in 1100 feet and being driven as rapidly as possible with three drill shifts of one drill each. Some days as much as 10 feet are made.—Work on the Grand Prize is under the supervision of W. Friend of Pitkin.

F. O. Ensign is sinking 100 feet on the Cortland mine, near Obio City. The Cortland dump is to be treated in the Jersey Blue mill. Near Obio City work has been resumed at the Golden Eylet, Chloride and Philips.

Lake County.

The Belgian mine, in Adelaide park, near Leadville, has arranged with the Yak tunnel people to drive a lateral from the tunnel level 1500 feet to the shaft of the Belgian. This means that the property will be drained of water, as well as the other claims in the neighborhood, and when the lateral reaches the shaft a raise will be made to connect the two. When the Belgian is reached and the ore body opened all of it will be taken out through the tunnel.

The Nil Desperandum Co., at Leadville, has put in extra boilers and pumps to handle the water so that sinking can be resumed in the shaft.—The Penrose Co., at Leadville, has put in new pumps to reduce the water level in their mine.

The Manhattan M. & P. Co. has resumed work on its crosscut being run to cut the Keystone ledge at Willis Gulch, near Twin Lakes. O. P. De Ford is president.

Ouray County.

D. L. Brown has commenced work on the Bullion property on a lease and is cleaning out the shaft and making ready for running on the vein.—Lack of coal has caused the Treasury tunnel, near Ouray, to be closed down.—It is reported that the Bagley tunnel, near Animas, is in 400 feet and has intersected a body of lead-silver sulphides of good values. Ten men are at work.—W. R. Kramer has started work on the Governor, near Ouray.—The Revenue Tunnel Mines Co. of Ouray are working 250 men, and will probably increase the force to 400. The water is under control.

San Juan County.

The Green Mountain Co.'s new 75-ton concentration plant near Howardsville is expected to be in operation by July 15. Ed. Walter is manager.

The Boston & Silverton M. & R. Co., at Silverton, have struck good ore in the Yukon tunnel, at a vertical depth of 1500 feet, 2135 feet from the tunnel mouth. A. A. Lamont is superintendent.—The Mollie Mack group, on the northwest slope of Boulder mountain, is to be worked by the Little Rea G. M. & M. Co., of which E. W. Hunt of Silverton is manager. A 2000-foot tunnel will be driven to work the vein.

San Miguel County.

The 50-stamp mill of the Ophir Con. M. Co. at Ophir Loop has been remodeled to handle the tungsten ore and is expected to start May 1.—The 80-stamp mill of the Liberty Bell mines at Telluride is expected to be ready for work on April 10. More men are being put on at the mine and the force will probably be increased further when the mill is started. The Stilwell tunnel being run to cut the Liberty Bell vein, 900 feet below the upper workings, is in over 1000 feet.—Wagner Bros., lessees of a portion of the Smuggler-Union mines and dumps at Telluride, who are working twelve men, will be employing seventy-five men, it is reported, by April 1. They expect to work the dumps extensively. It is calculated there are 3,000,000 tons of mineral in the dumps, some of which carries higher values in gold and silver than the bulk of the mineral which is being extracted from the mines at the present time.—King & Lindsey, lessees of another portion of the Smuggler-Union, with a force of 100 men, are taking out and sending to the Smuggler-Union mills, at Pandora, for treatment an average of 200 tons of ore every twenty-four hours. Besides the milling rock, they are sacking considerable high grade ore as it is taken from the mines, which is shipped direct to the smelters. They have thirty men working on their lease on the Sheridan mine, and will soon begin shipping.—At the Butterfly-

Terrible mines and mill, at Ophir Loop, Manager F. J. Keating reports that the mill is running to its full capacity and treating ten tons daily.

Teller County.

The Isabella Mines Co. of Cripple Creek has ordered a hoisting plant for the Empire State shaft, and a compressor and drills. The hoist is of first motion, good for 2000 feet. Sinking will begin at the 800-foot level and conclude at 1300 feet.

The Snowshoe M. & M. Co., on Sheep mountain, north of Gillett, will start work April 1 on the shaft of the Snowshoe claim No. 1, which is now down 200 feet. Crosscutting will be started to cut the vein which was uncovered at a depth of 100 feet. On the Snowshoe No. 2 the shaft, which is down 75 feet, will be sunk to the 150-foot level. Manager J. Parfot will work twenty-five men.—The Mountain Boy Leasing Co. has a two-year lease on the Mountain Boy and Bogart claims, on Raven bill, Cripple Creek. The company will operate through the Opbelia tunnel, which has cut the claims at depth of 1000 feet.—The Sioux M. Co. will start operations April 1 on the Flourine property on Copper mountain. The company is raising from the tunnel to make a connection with the old open stope. This will permit of the pay dirt being banded to the mill at a comparatively small cost.

J. F. Wright is building an ore house on the Jo Dandy, near Cripple Creek, preparatory to doubling his shipping output.—J. Whiting has charge of the work on the new lease of the Constantine, near Cripple Creek.

Sinking has been resumed at the Fortuna mine, Cripple Creek, preparatory to developing the property.

An electric hoist has been put on the Mary Cushen mine at Victor by Lessee Muelhausen.—J. Crawford has charge of unwatering the Sunset-Eclipse, on Battle and Squaw mountains, Cripple Creek. Ore will be taken out from the 350-foot level and sinking will be continued from the 500-foot level.—L. G. Henry is taking out good ore from his lease on the Peggy mine, on Gold Hill, Cripple Creek.—The Gold Sovereign Co. at Cripple Creek is sinking its shaft another 100 feet, which, when completed, will give it a total depth of 800 feet from surface.—Briggs and associates, who were operating under lease the south end of the Dante mine, have put a second shift to work driving the face of the Trail tunnel, which is nearly 100 feet from their ground. By driving this tunnel 100 feet ahead it will permit them to work their ground at a good depth, which will be much cheaper than sinking the shaft to gain the depth.

IDAHO.

Idaho County.

The Mercantile Finance Co. of Chicago have had twenty men working the Moose Creek placers in the Newsome mining district, on the road from Elk City to Stites, since Feb. 15. This property consists of 300 acres on the banks of the south fork of the Clearwater river, the more important gravel deposits being the remaining portions of sub-glacial river channels. C. H. Parsons of Newsome is manager.

In the Four Mile district, the Acacia B. M. & M. Co., owned by P. H. Leach and F. Ritchet of Grangeville, and near the Hogan properties, have done extensive development this winter. It is free milling ore.—Wm. Hogan of Elk City will have the mill working by April 15. A cyanide plant has been put in.

Owyhee County.

F. Barnes, superintendent of the B. N. & O. and Idaho Northern railways, and E. Matheson of Murphy, have located a deposit of tripoli 1 mile from Murphy. It is 85% silica and 15% lime. It is reported that Superintendent Orford of the De Lamar mine at De Lamar will work the mine from the lower tunnel.

Shoshone County.

J. H. Heward & Co. of Mullan have been working the upper level of the Snowstorm mine for nine months and paid the company in royalties on the ore shipped \$25,121.80, representing 15% of the net smelter returns on the ore, \$167,478.66.—As soon as the snow will allow, the Washington Light & Power Co. will extend its wires from Burke to the Oom Paul mine to furnish power for the electric hoist, which is to be built on that property. The Oom Paul management did intend to put in an electric pump, but this plan has been abandoned for the present, as the water in the shaft can be handled by hauling to a depth of 150 feet.—E. P. Spaulding, manager of the Monarch M. Co. at Murray, states that the new concentrator works satisfactorily. The bins are full of ore and the amount exposed in the mine assures a long and steady run. Water power is used to run the mill, but an auxiliary steam plant will be put in this summer.

MISSOURI.

Jasper County.

E. Boyd of Carterville will build a 100-ton mill for the Trossac M. Co. at Alha.—The Batavia mill, south of Carterville, has been started.—The Quaker mill at Chitwood is running full time and making ten tons of ore per shift.—G. W. Landreth and others are sinking a shaft on a lease south of Chitwood. They are down 160 feet.

MONTANA.

Gallatin County.

At a depth of 2300 feet an 11-foot vein of coal has been struck in the properties of the Amalgamated Copper Co., at Storrs. The Amalgamated Co. is the largest consumer of coal in the State, and the finding of such a large vein will mean a saving. As a result of the action of the railroads in making a proportionate rate, dependent upon the grade of the ore, the East Helena smelter is receiving vast quantities for treatment. The Florence mine at Neihart has contracted for the delivery of 10,000 tons of low-grade ores that could not have been handled except for the reduced freight rates.

Jefferson County.

The Red Bird M. Co. will start work on the Reliance mine in High Ore gulch, near Basin.—The Leadville M. Co. have decided to build a concentrator and smelter and to develop their mines at the head of Cottonwood gulch, near Basin. J. C. McFadden of Butte is manager.

## Lewis and Clark County.

The Whitlatch-Union mine, 4 miles south of Helena, is shipping ore regularly to East Helena. A new shaft has been sunk to a depth greater than the old workings and it is from the new ore bodies recently discovered that the shipments are being made.—The Helena mine, 2 miles west of Helena, is producing galena ore which runs 40% lead and good values in silver. On the Luby claim, which adjoins the Helena, a 4-foot vein of similar ore has been found. A 5-foot galena vein has been struck in the property of the South Bend M. Co., in the Ontario district.

## Madison County.

The shaft of the Green-Campbell M. Co., near Silver Star, is down over 400 feet. They plan to build a small stamp mill this season.—The Strawberry mine, near Pony, is to be started up.

C. Estes has leased the B. W. & G. mill in Nugget gulch, near Sheridan, to treat the ore from the Mollie Gibson.—At Brandon, a larger hoist is being put on the Toledo mine.

## Missoula County.

The Tarbox M. Co.'s group of claims, 3 miles north of Saltese, on Packer creek, is to be equipped with a 50-ton concentrator. Richard Daxon is president of the company.

## Silver Bow County.

The work of sinking the shaft of the Raven mine in Centerville, 5 miles from Butte, from the 600 to the 700-foot level, has been completed. A station is being cut and timbers put in. The company has bought a large engine that will enable them to sink 1700 feet. Since the work of sinking the shaft was commenced, an excellent streak of ore has been uncovered on the 600-foot level that promises to develop well. H. Tonkin has charge of the work.

## NEVADA.

The Sundry Civil Appropriation Act, approved by President Roosevelt on March 3, provides that out of \$400,000 for surveys and resurveys of public lands, there may be expended for surveys in the mining regions of Nevada situated south of the first Standard parallel north of the Mount Diablo base line not to exceed \$25,000. It is the intention of Surveyor-General Kyle to let contracts to deputy surveyors for the survey and subdivision of the townships embracing the chief mining districts of Nye, Esmeralda and Lincoln counties to the full extent of the appropriation. The Act also provides \$15,000 for the completion of the public building at Reno.

## Esmeralda County.

(Special Correspondence).—The New Western Reduction Co. sampler and custom mill at Goldfield is ready for the machinery and may be running within thirty days. The full capacity of the sampler—100 tons—has been arranged for by local shippers and the 10-stamp mill is to be increased to twenty stamps. The Goldfield mines are steadily continuing in their output and appear to be proven to a depth of 300 feet, showing up strong values in sulphides and tellurides.

Goldfield, March 20.

A new strike of high-grade ore has been made by S. McGibbon of Goldfield for the Butte Goldfield M. & R. Co., 12 miles south of Thorpe's mill.—The Haseltine group, at Bullfrog, has been sold to W. A. Sherman, J. P. Loftus and J. R. Davis, who will develop the property under the direction of N. P. Reinhard.

## Lincoln County.

G. C. Fetterman of Caliente has sold the control of the Caliente G. M. Co. properties at Caliente to D. R. Kilbourne, C. H. Kilbourne and J. J. Elwood of California and G. A. Paxman of Silver City, N. M.—It is reported that F. O. Wilkinson, superintendent of the Green Monster mines in the Yellow Pine district, in western Nevada, and W. J. Smith have located oil wells near Caliente.

## Nye County.

Work on the Paymaster mine at Lone Mountain has been resumed with W. Coulter as superintendent. —Manager F. A. Keith of the Tonopah M. Co. will put in a steam power plant, with an electrical transmission line, at the company's wells. These wells, in which an abundance of water has been developed, are 15 miles northwest of Tonopah, on the Tonopah railroad. The plant will consist of three McIntyre & Seymour engines and four B. & W. hoilers. The engines will have a total capacity of 1005 H. P., and there will be a sub-station on the Mizpah ground for the distribution of power to the company's mines. There will also be an electric motor to operate the compressors, ore crushers, sampling works and machine shops. The wire for the electrical transmission will carry 22,000 volts. Work on the plant will be commenced at once. The new ore bins being built by the company are nearing completion and a spur from the railroad is now being placed alongside of them.—W. Watt of Tonopah has uncovered a 4-foot ledge of copper and gold ore 5 miles northeast of Coaldale.

## Washoe County.

Reno reports that the freight embargo has been raised on all goods consigned to the mining camps in the southern portion of Nevada, and every department of the Virginia & Truckee, Carson & Colorado & Tonopah railroads are working to full capacity.

## OREGON.

## Baker County.

Superintendent Hansen of the South Pole mine on the head of Rock creek, near Baker City, says that he will begin shipping to the Sumpter smelter as soon as the roads are passable. The mill will be operated on sorted ore.

President F. P. Hays of the United Elkhorn Co., owning the Baisley-Elkhorn mine, near Baker City, says that deep sinking is to be started. The Baisley-Elkhorn is opened by an adit system above the level of the mill, and a shaft sunk 300 feet below this tunnel.

A new pumping plant is to be added to the I. X. L. mine, near Greenhorn, by Manager F. T. Kelly.—Bad roads are interfering with the delivery of ore to the smelter at Sumpter. The smelter bins are full of ore, and it is expected that with what is on hand and can be deliv-

ered there will be no danger of a shortage during the time roads are in the present condition.

Work at the Thornburg placers, operated by W. L. Vinson of Baker City, on the north fork of the John Day river, is being pushed. The tunnel through which water is to be carried to the placer ground has been completed and the pipes to connect with the flume are being laid preparatory to hydraulicking.

## Douglas County.

G. W. Lloyd, president of the Crystal Con. Co., near Bohemia, says the Crystal Co. has enough water for the summer. The new milling plant will be started this spring.

It is expected that the wagon road will be finished this spring from Oakland to the Bohemia district.—W. W. Shane has charge of development work on the Pittsburg group at Bohemia.—The Frisco Con. Co. of Bohemia is trying to save zinc and lead values occurring with the gold in their ores. Concentrators will probably be used.

## Harney County.

Production of borax at Lake Alvord, which is in the basin of the Dunder and Blitzen, near Burns, has become a permanent industry. California operators have developed the reduction work until they have a large tonnage, which is hauled 160 miles to Winnemucca, Nev., and thence taken by rail to San Francisco. The interior lakes of Harney and Malheur offer a large tonnage of saline products, and assurance is that extensive salt and borax works will be established in the region. At Abbot lake, near Paisley, Lake county, tests have been made which prove the worth of the waters for both borax and salt. Much of the land around this impregnated body of water is owned by the Pacific Live Stock Co., who have interested California men in reduction of both salt and borax, with success so far as the process was concerned, but the haul of more than 200 miles over bad roads proved too much of a handicap. Experimental work has also been done at Summer lake, Lake county. There work commenced on a dike, which was intended to confine the saline waters at the head of the lake in flood season, until the summer sun evaporated the water, when the salt and associated mineral would be scraped up and refined. Tests of the water were satisfactory, but the isolation of the district was too much. Numerous other lakes exist in the great interior country of Oregon, where important operations may develop when railway transportation gives a market for the product.

## Jackson County.

The 50-foot shaft of the Nellie Wright, near Goldhill, is to be sunk another 100 feet and new machinery put in by Manager Wetherel.

## Josephine County.

The Brantner placer mine, owned by Mansfield Bros. of Grants Pass, is shut down for this season, owing to the continued shortage of water. This mine is on the west side of Applegate river, 3 miles above Applegate postoffice, and water is had from Keeler and Chapman creeks.

A gold find has been made in Gold Ridge camp, the new district on Sucker creek above Holland, southern Josephine county. A number of the claims have been operated, the richness of the quartz showing good returns by the crude light mill, mortar or sluice method. On the White Swan a 1-stamp mill has been improvised. Near the White Swan, the Koepf claim is being worked with good profit by hand. A 20-foot shaft on the Little Gem claim uncovers a 4-foot ledge of good quartz. J. Barnett will develop it.

Mining at Eureka is contingent on the success of navigation of Snake river, at least until there is improved transportation to the district, says the Oregon Journal. Senator W. B. Heyburn's success in having an appropriation of \$25,000 made to improve the river between Lewiston and Eureka will result in clearing the channel over the worst rapids. Nothing definite has been received in the upper camps as to the time when Major Langfitt will be able to get the Wallowa dredge at this work. At the Eureka property fire partly destroyed the electric machinery. The management took the power drills out of the tunnel and put in single-jack shifts. The power plant will be rebuilt and new machine drills put in.—J. A. Hillicker, manager of the Western Union property, near Eureka, is building a road to the group and may put in a development plant this season.

At Grants Pass on March 20, B. Savage of the Alameda mine defeated Waters of Sumpter in a drilling contest of fifteen minutes straightaway, 29½ inches against 26 inches. Savage on Saturday drilled 36½ inches in fifteen minutes, but Waters did not drill on account of the rock splitting, and a return match was ordered to be drilled. Lockwood of Alameda turned for Savage and Seligo of the Granite Hill mine for Waters.

## Lane County.

Manager W. B. Dennis of the Black Butte quicksilver mine, near Cottage Grove, has his new experimental furnace completed.

## SOUTH DAKOTA.

## Lawrence County.

At the Hidden Fortune, near Deadwood, ore has been struck on the 200-foot level of the Bingham shaft by Manager T. J. Steele.

## Pennington County.

President A. R. Arundale, of the Gopher M. Co. is moving the Sunnyside mill to the Gopher property at Hill City to a site selected by Consulting Engineer A. H. Elltman of Hill City. The management may add five stamps.

## UTAH.

## Juab County.

The ore shipments from the Tintic mines for week ending March 18 were: Centennial-Eureka 91, Bullion-Beck 6, Gemini 15, Ajax 3, Carisa 1, Grand Central 7, Mammoth 13, Lower Mammoth 1, Victor 3, Marlow and Baxter 1, May Day 9, Yankee Con. 9, Uncle Sam Con. 3, Eagle & Blue Bell 7, Swansea 2; total, 171 carloads.

At the Centennial-Eureka mine, at Eureka, 300 men are working. In order to handle the increased tonnage another shift has been employed on the tramway which

is used to convey the ore to the two railroads. New ore bodies are being opened up in the properties on the lower levels, and it is the intention to sink the 2100 shaft to a greater depth.—The McKinley M. Co.'s tunnel is in 116 feet, and from the report of Superintendent E. Levin of Eureka it is expected that it will soon tap the vein towards which it is directed.—The shaft of the Victoria M. Co., in North Tintic, is to be sunk another 100 feet by R. S. Robertson, the superintendent.—The Rio Grande Western Railway will build a spur to the property of the Eagle & Blue Bell M. Co. near Eureka. The company will build a large ore house so as to handle the output of the mine.—West Tintic is to have a custom mill, according to C. W. Jones, superintendent of the Bonanza property. He has secured an option on some ground in the west end, and the mill will handle the product of the different properties.

## Salt Lake County.

The Bingham Con. Co. has 300 men at work at the Dalton and Lark group. The Mascot tunnel is almost under the Dalton and Lark workings, being in nearly 8000 feet. A new electric locomotive has been put in the tunnel. The compressed air plant is furnishing air to seventeen machine drills and seven hoists.

The Fortuna Co. at Bingham is working forty-two men, under the direction of Superintendent J. Start. In the Freedom tunnel connection has been made with the Portland incline, which gives good air. The Mayflower tunnel has been cleaned out, and will be further explored and developed.

G. R. Bothwell and R. E. McConaughy have resumed work at the Congor mines at Bingham.

Chas. M. McNeill, president, and Spencer Penrose, secretary and treasurer of the Utah Copper Co., are at Bingham to decide upon the erection of a new plant, also its capacity and location. The company has 100 acres on both sides of Bingham Canyon, formerly owned by the De Lamar-Wall M. & S. Co., 320 acres bought from the West Mountain Placer Co. and a 320-acre mill-site near Garfield Beach, Saltair, Great Salt Lake. The Bingham Canyon property is developed by tunnels and has been extensively prospected with diamond drills. The country rock is a soft friable porphyry, the ore being disseminated chalcopryrite said to average 2.3% copper, ½ ounce silver and .03 ounce gold per ton. The company's present plant below Bingham is reducing and concentrating 800 tons a day.

## Sevier County.

The Copper Butte M. Co. of Richfield has contracted with W. J. Shelton for an additional 100 feet of opening in the Shelton No. 2 tunnel. This tunnel is in 100 feet.—It is reported that the Perdue-Surprise Co. will resume work at Richfield.

## Summit County.

In the annual report of the Daly West Co., at Park City, F. W. Sherman, the mill superintendent, reports that the basis of concentration was 5.98 tons into 1. The assay value of the ore milled was 5.85% lead and 14.5 ounces in silver. The assay value of the tailings was fourteen one-hundredths of 1% lead and 4.1 ounces silver. Thus the theoretical saving was 98% of the lead and 71.7% of the silver, while the actual saving, based on the concentrate sold, was 99.3% of the lead and 70.5% of the silver. While the plant can save the lead values almost to an entirety, the recovery of the silver still presents a problem needing further solution. The tailings plant, which has been in operation since the first of last May, has produced 1680 tons of dry concentrates. There is no question that a further treatment of ore through an additional plant can be made to pay high profits. Plans for such a plant have been prepared and await instructions from the directors. As the different ore bodies are worked nearer to the surface, more chloride of silver is encountered; also the Daly vein, in the eastern portion of the mine, below the 1200 level, yields ore low in lead and high in silver values. These ores require a much finer crushing, and even the silver values are more difficult of recovery than the values in ores treated in years past. Manager Ernest Bamberger says the mine produced 58,268 tons of ore during 1904, from which were received \$1,804,672.83. There were 23,355 tons of crude ore extracted, which averaged \$31.32 to the ton; 14,440 tons of crude ore from the Quincy mine, averaging \$21.16 to the ton; 15,207 tons of concentrates were produced from the mill, averaging \$39.83 to the ton, while 267 tons of mill crude sold for \$30.58 per ton. From the foregoing were obtained 2,023,005 pounds of copper, 25,651,444 pounds of lead, 2376.36 ounces of gold, 3,064,224 ounces of silver and 13,025,408 pounds of zinc.

## Tooele County.

Superintendent T. W. Galliger of the Stockton Gold M. & M. Co. of Stockton states that the mine will start shipping from the new ore shoot on the 700-foot level. The mill has been running ten hours per day.

## Utah County.

The High Ball M. & M. Co. has been formed to work the High Ball claims in Rock canyon, Utah county, by J. E. Armistead, president, L. L. Bean, vice-president, and W. A. Johnson, secretary and treasurer. The company's office is in Provo.—The Mariot M. & M. Co. has been formed to work the Mariot. J. E. Booth is president.

## WASHINGTON.

In the report of C. F. Owen, State Inspector of Coal Mines for 1903-04, the coal production of Washington was 3,190,477 tons. Pierce county reported 47,916 tons of coke. Coal at the mine averaged \$2 per ton, coke at the oven \$5 per ton. The total value of coal and coke produced was \$6,620,534. To make this product the wage cost was \$3,982,184, the average of coal per employee per day being 2.13 tons. Coal is produced in several counties of Washington, Kittitas county producing nearly one-half of the total. There were 4876 employees, averaging wages of \$2.67 per day. One life was lost for each 127,619 tons of coal produced.

## King County.

The Apex mine, near Berlin, has been making regular ore shipments to the Ladysmith smelter on Vancouver Island, and will put in an air compressor and drills.

## Okanogan County.

The Copper World Extension M. Co., on Palmer moun-

tain, near Loomis, is preparing to do considerable development work. H. Bahr, superintendent, says the shaft is in 100 feet and will be continued 500 feet. A hoisting plant, air compressor and boiler are being put in.

J. H. Arnold of Columbus, O., has been at Chesaw in the interest of the Olenzang M. Co., of which M. A. Smalley of Chesaw is president and manager. The property is 4 miles northwest of Chesaw. A shaft has been sunk on the ledge 60 feet deep and a tunnel 200 feet long has been run. The company has purchased a whim hoist and sinking will be continued.

#### Pierce County.

W. R. Rust, vice-president and manager of the Tacoma Smelting Co., says that the Tacoma and the Everett smelters are to be consolidated, but that they will not be controlled by the American S. & R. Co. The electrolytic copper refinery at the Tacoma smelter has commenced operations.

#### Stevens County.

G. Almstrom of the Double Standard mine, on Sheep creek, near Northport, says the tunnel is in over 700 feet and will tap the ledge at depth of 250 feet.

Smelter returns from the first car of ore from the Ben Vennuo mine, containing 20½ tons, amounted to \$45.13 per ton, of which \$42.31 was in gold, the remainder in silver. The property is owned by H. W. & G. H. Sparks of Kettle Falls, and is 1½ mile from Meyers Falls station.—The Silver Queen mines, 2 miles south of Kettle Falls, are being worked by W. W. Warner of Spokane.

### FOREIGN.

#### AUSTRALIA.

From the returns available, the Australian gold production for 1904 was 4,111,462 fine ounces, or 113,213 ounces less than that of 1903. The figures from Queensland are incomplete. Western Australia produced 1,983,231 fine ounces; Victoria 765,600; Queensland 624,917; New Zealand 467,897; New South Wales 269,817; with a total of 4,111,462 fine ounces.

#### BRITISH COLUMBIA.

##### Boundary District.

The Montreal & Boston Copper Co. at Brown's Camp, 9 miles from Grand Forks, which recently bonded the Seattle mine, is making preparations to do development work. Aerial tramways are to be built at once.

T. H. Rea, general manager of the Betts & Hesperus mine, 4 miles west of Grand Forks, reports the compressor plant recently installed at the mine doing good work, and he expects that the mine will soon be shipping ore to the Granby smelter.—A steam plant has been put on the Bay mine, near Grand Forks.—Work has been discontinued at the Senator mine, near Grand Forks, by Foreman Rogers. This property was bonded to the Granby Co., and has been worked for several months, 3000 tons of ore having been shipped from the glory hole of the property. It is said the ore has given out.

The ore shipments and smelter treatments from the Boundary for the week ending March 18 were: Granby mines to Granby smelter, 12,385 tons; Mother Lode to British Columbia copper smelter, 3168 tons; Brooklyn to Montreal & Boston smelter, 2289 tons; Rawhide to Montreal & Boston smelter, 1949 tons; Mountain Rose to Montreal & Boston and British Columbia copper smelters, 132 tons; Emma to Nelson and British Columbia copper smelters, 217 tons; Oro Denoro to Granby smelter, 99 tons; total for week, 20,239 tons; total for year to date, 176,723 tons. Smelters treated ore as follows: Granby smelter, 12,243 tons; British Columbia copper smelter, 4423 tons; Montreal & Boston smelter, 4368 tons; total for week, 21,034; total for year to date, 193,881 tons.

##### Nelson District.

The Yankee Girl, the Canadian Girl and Yale fraction on Dundee mountain, 3 miles from Ymir, have been bonded for \$50,000 to C. J. Doyle of Chicago.

##### Roseland District.

The Trail smelter has torn down the last of the old Heinze gold-copper furnaces, and is putting in a new furnace, with a capacity of 350 tons a day. The old furnace had a capacity of about 150 tons a day. The smelter has now three large gold-copper furnaces, with a combined capacity of over 1000 tons daily.—The tonnage of ore shipped from the Roseland mines for the week ending March 18 was: Le Roi, 2275; Centre Star, 1440; War Eagle, 1620; Le Roi No. 2, 220; Spitzee, 240; White Bear, 125; White Bear (milled), 600. Total for week, 6250 tons, and for the year, 74,676.

The manager of the Le Roi No. 2, at Roseland, has recommended that they start sinking in the main shaft from the 900-foot level to a depth of 1450 feet. They have made a contract with the Trail smelters to reduce its ores.—The Mavis, adjoining the Bay claim, in Skylark camp, has been bonded by D. B. Morkill, J. J. Strutzel, G. L. McNicol, W. X. McDonald, C. M. Campbell and J. A. Hanna of Phoenix for \$15,000.—J. C. Haas will start work on the Golconda in Deadwood.

##### Slocan District.

It is reported that the "L. H.," near Silverton, is to be developed this season.—The Rockland Copper Co., in which W. W. Sparks of Vernon and F. Watson of Spokane, Wash., are interested, will develop the Rockland, near Silverton, this spring.—N. F. McNaught of Silverton will start work on the Little Daisy.—The lead ores of the Galena, near Silverton, are being developed by a company in which C. H. Hand of Butte, Mont., and A. W. McCune of Salt Lake City, Utah, are interested.—Nicholson & Galloway of Silverton are working the Noonday under lease.—The Hewitt mine, near Silverton, is shipping steadily and developing ore reserves. M. S. Davy has charge. Thirty men are employed.—The Lorna Doone is being worked from the Hewitt tunnels. M. S. Davy has a bond and lease on this, as well as the Emily Edith, where he is working ten men.—G. Wyland of New Denver has eight men at work on the Standard-Surprise group.—It is re-

ported that the Wakefield mine, 4 miles above Silverton, on Four-mile creek, is to be started.—D. Brandon is working the Mountain Broomer under lease.—The Fisher Maiden, 7 miles above Silverton, is being worked by C. Twitchell of Spokane, Wash.

### CANADA.

#### Ontario.

According to a consular report, a vein of silver has been discovered on lands north of Massey and the Bruce mines, near North bay. Four carloads of ore shipped to New Jersey netted \$60,000.

#### INDIA.

The report of the Chief Inspector of Mines in Mysore, W. F. Smeth, for 1903-4 shows that the gold value during 1903 was £2,288,429 for the fine gold. During 1903 five mines (Champion Reef, Mysore, Oorogum, Nundydroog and Balaghat), producing 98% of the total output, paid dividends: three. Coromandel, Mysore West and Mysore Wynaad, produced £43,927 worth of hullion; six. Road Block, Oriental Gold, Kempinkote, Kadur-Mysore, Gold Fields of Mysore and Nine Reefs, worked without production, and the Mysore Nagar closed down. Active development has been carried out at the Bellara Block and in the East Betarayawami and Bodimardi further prospecting is contemplated. On an ore carrying very little base material, the following are some of the cost items for 1903: Value per short ton milled, 88.25s.; total cost per short ton milled, 28.205s.; mining cost per short ton milled, 20.25s.; milling cost per short ton milled, 3.77s.; cyanide cost per short ton milled, 1.77s. Coal costs the mines 21s. a ton—while most of the electrical power used was charged for at £29 per horse power per annum, though this figure is to be reduced this year to £18. The average weight of the stamps in the six chief mines of the field is 1037 pounds, giving a duty of 3.63 tons a day, against the Transvaal figure of 4.8 tons for a somewhat heavier average head. With the exception of preliminary breaking in the rock crushers, the stamps do the whole of the crushing, the ore being amalgamated in the mortar boxes and the pulp passed through 34.7 mesh. This is the finest crushing it receives. The pulp is then stacked in heaps for some months to weather before cyaniding, in order to obtain further comminution of the particles by atmospheric action. Cyaniding yields an average extraction of 61½%, with the result that the residues contain from 4s. to 5s. of gold. Spitzkasten are being experimented with; secondary rock breakers are being tried at Ooregum, a tail rope is to be tried in the new Oakley shaft at the same mine, and the continuation of the shaft on the incline is in the foot wall instead of in the lode itself. The total labor force was 27,355, divided as follows: Whites, 239 below ground, 290 above; Eurasians, 99 below ground, 303 above; natives, 17,237 below ground, 9729 above. The number of fatalities per 1000 below ground was 3.29, and above 1.13.

### MEXICO.

#### Chihuahua.

The Parral Miner reports that A. de Lantreppe of Parral has taken charge of the Buen Viento mine, north of Palmilla hill, the contractors, Weisel & Koch of Parral, having finished the 300-foot two-compartment shaft. Ore was struck at a depth of 115 feet in a crosscut driven towards the vein, which proved to have a width of 16 feet. The first shipments were made in December last averaging 800 to 900 grams silver. Another crosscut has been started, which is to cut another vein. On the El Faro claim Weisel & Koch have sunk the three-compartment shaft 160 feet, and will be continued to cut the San Patricio vein at a depth of 300 feet. When finished they will put in a 100 H. P. gas hoist and producer. The three-compartment shaft being sunk on the Gran Bretano by the same firm to cut the Refugio vein is down 40 feet, and will be equipped with a 50 H. P. gas engine. These claims belong to the Buen Viento Co. of New York, who have also bought the San Rafael and San Cristobal properties.

The Parral Deep Levels Co. is developing the Florentina property under the management of J. F. Flynn of Parral.—It is reported that the Hidalgo M. Co. will work most of their mines in the Parral district this year.—The United States M. Co., under the management of J. W. Marshall, is shipping to the Parral Milling Co.

#### Durango.

The Guadalupe mines at Inde, belonging to D. G. Benton, have been examined by H. J. Jessop. The Guadalupe, Fundicion Plomoso, Potrillo, La Luz, Raton and Marias mines are all being worked at Inde.

J. Rawlings, manager of the Socaban mines for Hearst & Haggin at Tayolita, is to build a 40-stamp mill at the mines. The present mill is of five stamps.

#### Guanajuato.

The cyanide plant of the Guanajuato Con. M. & M. Co. at Guanajuato is treating ore from the Sirena y Anexas. The silver value is greater than the gold. Manager M. E. McDonald has done considerable development work in the mine.

#### Hidalgo.

The Argentine y Anexas M. Co., City of Mexico, proposes to build a 20-stamp mill and concentrator at their mine at El Chico, Pachuca.

#### Jalisco.

J. R. Bickerdike of Guadalajara, one of the owners of the Rosa Amarilla mines, reports that the company has a concession for an electric line from the mines to the Pacific port of Navidad, and plan to extend the road to Autlan.—N. W. Kinross, manager of the Chatterton M. Co. operating at Tapalpa, states that 50 men are developing the veins on the property. The mill and concentrators will be started.—The Jalisco Times reports that H. H. Sawyer of Philadelphia has bought the mines of the Bautista M. Co. in Bautista, 75 miles south of Ameca. B. McLellan has been managing the mines. J. H. Howard has been secretary. Steam hoists and steam pumps have been put in and the high grade ore mined has been shipped to the smelters. It is the intention of

Sawyer and associates to build reduction works and treat the ore at the mines.—F. C. Helm has bought the Agua Blanca copper mine, near Santa Rosalia, from D. Furness of Guadalajara and B. M. Esler.

#### Michoacan.

It is reported that the copper mines at Inguaran are to be worked by the Paris Rothschilds. M. Rohellar is at the property to determine plans for operations.

#### Sonora.

(Special Correspondence).—The production of copper by the Cananea Copper Co., at La Cananea, for February was over 5,000,000 pounds, an average of ninety tons per day. So much rain has fallen that the water has seeped through the ground to the workings, greatly hampering the mining. The ore in the chutes is so soggy it will not run and has to be loaded into the cars by hydraulic pressure. Slides have occurred on the railroad and for several days Puertocito could not be reached, delaying the delivery of lime, wood and clay for the converter linings, and greatly inconveniencing operations at the smelter.

La Cananea, March 17.

### RHODESIA.

Superintendent T. G. Davey of the Rhodesia Broken Hill property, in northeast Rhodesia, says that the mine is on a high plateau, at an altitude of 4000 feet. The metals are lead and zinc, which occur as carbonates, silicates, oxides, and a small percentage of sulphides, distributed over a considerable area, and conspicuously so in a number of large outcrops or kopjes, of which these minerals constitute the predominant proportions.

## Commercial Paragraphs.

R. J. CORY, 244 Equitable Building, Denver, Colo., has an order for a silver-lead smelting plant to be shipped to the Los Arkos S. & M. Co., Toluca, Mexico.

E. H. BANGS has resigned as engineer and salesman of the Byron Jackson Machine Works of San Francisco, to take a similar position with the United Iron Works, 32 Fremont St., San Francisco, Cal.

CARY & FIELDING, 1711 Tremont St., Denver, Colo., report the sale of two Cross-compound steam and air Rand compressors, 10 drill each, for shipment into Colorado; they have also an order for addition to cyanide plant of Dorcas mill, Florence, Colo. They report good sale on Cameron pumps, of which they have the Colorado agency.

THE Sullivan Machinery Co. of Chicago announces the establishment of a new branch office in Salt Lake City, Utah, room 128 Keith building, John C. Taylor, formerly of the Denver office, manager. The new office will carry a full line of Sullivan straight line air compressors and rock drills, with mountings, equipment and duplicate parts in stock.

THE Risdon Iron Works of San Francisco, Cal., has secured the right to use the pump patents of Sulzer Bros., builders of the Sulzer centrifugal pump exhibited at the Paris Exposition of 1900. They have incorporated these ideas in the design of a centrifugal pump to be known as the "Risdon-Sulzer," and have finished a careful series of tests with one of their standard belt type, two-stage machines. Invitations were recently issued to pump builders and several leading business men, interested in pumping machinery, to visit the works and see this pump in operation and under test. The Risdon Iron Works reports that on that occasion the pump showed high efficiency: "During the test the pump delivered from 450 to 725 gallons of water per minute, to heads ranging from 100 feet to 260 feet, with an efficiency ranging from 72½% to 79%. No allowance for work lost by belt and shaft friction was made, although this is generally taken into account in testing centrifugal pumps. It is safe to say that this would account for at least 2½%. In other words, had the pump been direct connected to an electric motor, the test would have shown 75% to 80% efficiency, a most unusual result for this class of pumps."

## Books Received.

"Biennial Report of the Missouri State Geologist," by E. R. Buckley, gives an account of the objects of the Missouri Bureau of Geology and Mines, a review of what it has accomplished, and a brief account of the State's mineral resources.

Denny's prospectors' map of Nevada mining districts and part of southeastern California shows wagon roads, trails, railroads, watering places, etc., and is compiled from late authentic data. It will be sent postpaid anywhere on receipt of 75 cents at this office.

## Trade Treatises.

Catalogue No. 15 of the Union Steam Pump Co. of Battle Creek, Mich., describes the Burnham steam pump. In addition it contains much valuable information on capacities of pumping plants.

The Hardsocg Wonder Drill Co. of Ottumwa, Iowa, and 1744 Broadway, Denver, Colo., send a well illustrated booklet describing the Little Wonder air hammer rock drill and the Herron & Bury compressors.

Gold milling machinery of the latest types is attrac-

tively set forth in Catalogue No. 16 of the Joshua Hendy Machine Works of San Francisco, Cal. The illustrations of crushing and milling machinery are especially fine.

The Wellman-Seaver-Morgan Co. of Cleveland, Ohio, issue a neat booklet describing and illustrating the Dewhurst slag ladles and cars.

## Personal.

A. B. CANFIELD of Bakersfield, Cal., is in San Francisco, Cal.

L. S. SHOENFELD is manager Boulder Reduction Co., at Jamestown, Colorado.

F. J. TOUSSANT is manager La Chumata silver mine near Arizpe, Sonora, Mexico.

LEONARD SIVYER of Los Angeles, Cal., is at Prescott, Ariz., on professional business.

D. C. JACKLING has been made manager Bingham Central Co. at Bingham, Utah.

THOMAS FIELDING of the firm of Cary & Fielding, Denver, Colo., is in Chicago, Ill.

J. T. BOGAN has returned to Park City, Summit county, Colo., from Stockton, Utah.

B. C. RIBLET, manufacturer of the Riblet tramway, Spokane, Wash., is in St. Louis, Mo.

A. M. LIGHT has charge of work of the Standard Group Marble Co. near Bossburg, Wash.

ARTHUR W. JENKS, M. E., of Salt Lake City, Utah, is in Nevada examining mining properties.

CHAS. CHAMPLIN has returned to his dredging property on Footh creek, near Gold Hill, Oregon.

N. TREWEEK, SR. of Lead, S. D., has been appointed State Inspector of Mines to succeed T. Gregory.

C. H. MUNRO is superintendent Oroville Gold Dredging & Exploration Co., Oroville, Butte county, Cal.

F. R. BALDWIN, superintendent Maitland property, has returned to Deadwood, S. D., from Chicago, Ill.

JOHN DEE is manager Cacomia M. & S. Co.'s additional mines and smelter, near Autlan, Jalisco, Mex.

T. T. HARDING is manager Gladstone M. Co., owning the Macedonian mines, 12 miles northeast of Nogales, Ariz.

WM. THOMPSON, consulting engineer for the Velvet-Portland M. Co., has returned to Rossland, B. C., from Ocampo, Mexico.

J. L. BRYSON of San Francisco, Cal., has gone to Goldfield, Nev., to take superintendency of the Goldfield-Badger property.

C. J. STONE (with Dickman, Mackenzie and Potter, 1120 Rookery), Chicago, Ill., is inspecting mining properties in Colorado.

J. C. GOODIER is manager and T. S. Davidson is superintendent Abundance M. & M. Co. at Breckenridge, Summit county, Colo.

TODD C. WOODWORTH of the New Western Reduction Co., Goldfield, Nevada, has returned to that busy camp after an Eastern visit.

GEO. L. HOLMES has removed from Folsom, Cal., to Oakland, Cal., and contemplates gold dredger mining practice in San Francisco, Cal.

ED. HOFFMAN, formerly superintendent Silver Shield at Bingham, Utah, has been appointed superintendent Carisa M. Co. at Eureka, Utah.

J. B. JENSON has resigned as manager Pioneer Smelting Co. at Sandy, Salt Lake county, Utah. A. J. Cushing has resigned as superintendent.

R. P. AKINS, representing the Colorado Iron Works Co., Denver, Colo., has returned there from an extended trip through Nevada, California and Arizona.

E. J. WILSON, formerly superintendent Le Roi smelter at Northport, Wash., has been appointed superintendent of the Yampa smelter at Bingham, Utah.

W. C. MILLER of Wallace, Idaho, succeeds E. J. Roberts as general manager Federal M. & S. Co. The latter resigns to become chief executive officer Spokane & International Ry. Co.

J. H. FENNESSY, president, and A. H. Seep, vice-president of the Mine & Smelter Supply Co., Denver, Colo., have gone on a three months trip to Havana, Vera Cruz and City of Mexico.

H. E. WEST, late superintendent La Leonessa mine, Matagalpa, Nicaragua, C. A., has accepted a position on the engineering staff of R. M. Raymond, general manager El Oro mine, Mexico.

CHAS. H. MCMAHAN has resigned the general superintendency of the Montezuma Lead Co., Santa Barbara, Chihuahua, Mexico, and removed to El Paso, Texas, where he will engage in engineering practice.

## Obituary.

C. V. LOGAN of Denver, Colo., was shot and killed in an Indian hut at Lida, 20 miles south of Goldfield, Nev., on March 19.

MEYER GUGGENHEIM, one of the most eminent and conservative financiers of the United States, died at Palm Beach, Fla., March 16, of pneumonia. He was the creator and builder of the firm of Guggenheim's Sons of

New York, well known in the smelting business and mining world.

JOHN G. RHODIN died March 21 at Park City, Utah, where he had charge of the American Flag mine. Rhodin was engaged in mining for a third of a century and had worked in California and Oregon mines a great many years, being at one time superintendent of the Virtue mine at Baker City, Or.

## Latest Market Reports.

SAN FRANCISCO, March 24, 1905.

### METALS

SILVER.—Per oz., Troy: London, 26½d (standard ounce, 925 fine); New York, bar silver, 58½c, refined (1000 fine); San Francisco, 58½c; Mexican dollars, 48c, San Francisco; 48½c, New York.

COPPER.—New York: Standard, \$15.50; Lake, 1 to 3 casks, \$15.37½; Electrolytic, 1 to 3 casks, \$15.37½; Casting, 1 to 3 casks, \$14.87½. San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18½c. London: £67 17s 6d spot per ton.

The copper market remains firm and practically unchanged. The total stock on hand reported March 1 was 12,000 tons with a visible supply due to shipments afloat from Chile (3571 tons) and Australia, (1550 tons), a total of 17,125 tons. An English authority says of the market: "The present level of prices for copper appears to be now firmly established and a further advance in price is very probable in view of the increased consumption in the United States, the large shipments to China, and the activity in the shipbuilding, engineering and electrical trades, both in England and on the Continent, with no immediate prospect of any material increase in the supplies."

Following are the figures of German consumption of foreign copper for the month of January, 1905, compared with the same period of time for 1904-1903:

	1905. Tons.	1904. Tons.	1903. Tons.
Imports.....	7,500	9,391	6,828
Exports.....	925	676	795
Consumption.....	6,574	8,715	6,034

Out of the above, 6169 tons were imported from the United States.

LEAD.—New York, \$4.60; Salt Lake City, \$3.50; St. Louis, \$4.12½; San Francisco, \$3.70, carload lots; 4½c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5½c; pig, \$4.85. London: £12 8s 8d per long ton.

SPELT.—New York, \$6.15; St. Louis, \$6.15; London, £23 7s 7d per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

TIN.—New York, pig, \$29.70@29.90; San Francisco, ton lots, 31c; 500 lbs., 31½c; 200 lbs., 32c; less, 33c; bar tin, 3½c, 35@37½c. London, £136 5s.

PLATINUM.—San Francisco, crude, \$18.50 per oz.; New York, ingot, \$19.50 per Troy oz. Platinum ware, 75@82c per gram.

QUICKSILVER.—New York, \$40.00@41.00, large lots; London, £7 12s 6d; San Francisco, local, \$38.00 per flask of 75 lbs.; Denver, \$45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 19.75c; San Francisco, Plumbers', 100-lb. lots, 16.50c.

ZINC.—Metallic, chemically pure, 50c; dust, 3½c, 10c; sulphate, 3½c, 10c.

NICKEL.—New York, 55@60c per lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c per lb.; 100 lbs., 35c; 1000 lbs. 34c; ton lots and over, 33c, Pittsburgh. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburgh.

### STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$16.35@16.85; gray forge, \$16.65; San Francisco, bar, 3c per lb., 3½c in small quantities.

STEEL.—Bessemer: hillets, Pittsburgh, \$23.00@27.00; open hearth billets, \$23.00@27.00; San Francisco, bar, 7c to 12c per lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, ½c per lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LUMBER.—(Retail): Pine, ordinary sizes, \$24.00@5.00; extra sizes higher; redwood, \$28.00@30.00; lath, 4 cts, \$4.50@5.00; pickets, \$21.00; shingles, \$2.50 for No. 1 and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00@35.00.

NAILS.—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.55; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d, Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4d and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

LIME.—Santa Cruz, \$1.25 country, \$1.25 city per bbl.

CEMENT.—Imported, \$2.15@2.65 per bbl.; California, carload lots, \$1.90 f. o. b. at works; small lots, \$2.20 per bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

### GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 7½c; Hallett's, 7½c; San Francisco, 1000-lb. lots, 9c; 300@500-lb. 9½c; 100-lb. lots, 10½c.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lot, Eastern and foreign: Wallend, \$7.50; Brymbo, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8.00; Cumberland, \$13.00; Cannel, \$8.50; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13.00 in sacks; Sunnyside, \$8.50, long ton.

POWDER.—F. O. H. San Francisco: No. 1, 70% nitro-

glycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1\*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1\*\*, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg.

CAPS.—3x, \$5.50@6 per 1000; 4x, \$6.50@7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

FUSE.—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c per set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c per lb.; carloads, 23@23½c; in tins, 30c; soda ash, \$2.00 per 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c per lb.; Cal. s. soda, bbls., \$1.10@1.20 per 100 lbs.; sks., 90c@1.00; chlorate of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2½c; powdered sulphur, 2½@2½c; flour sulphur, French, 2½@—; alum, \$2.00@2.25; California refined, 1½@2c; sulphide of iron, 8c per lb.; copper sulphate, 5½@5½c; chloride of lime, spot, \$2.50@2.75; sulphuric acid, in carboys, 66% B. 1½@2c per lb.; nitric acid, carboys, 8c per lb.

OILS.—Linseed, boiled, hbl., 60c; cs., 65c; raw, hbl., 58c; cs., 63c; Lucol oil, boiled, hbl., 51c; cs., 56c; raw, hbl., 49c; cs., 54c. Kerosene—Pearl, per gal., 19c; As, tral, 19c; Star, 19c; Extra Star, 22c; Eocene, 21c, Elaine, 25c; Water White, in hulk, 12½c; Mineral Seal iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Minera; Sperm, cs., 26½c; Deodorized Stove Gasoline, hulk, 16c, do., cs., 22½c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in hulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 63c; Bleached, do., 57c; Whale Oil, cs., 52@57c.

BORAX.—Concentrated, 6@7c per lb.; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5@6c per lb.; No. 1, 4@5c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c per lb.

MOLYBDENUM.—Best, \$2.75 per lb.

CHROMIUM.—90% and over, 3½c, 80c.

PHOSPHORUS.—American, 3½c, 70c.

SODIUM.—Metal, 3½c, 50c.

BISMUTH.—Subnitrate, 3½c, \$2.10.

URANIUM.—Oxide, 3½c, \$3.50.

MERCURY.—Bichloride, 3½c, 77c.

TUNGSTEN.—Best, 3½c, \$1.25.

SILVER.—Chloride, 3½c, 90c@1.00; nitrate, 55c.

RED LEAD.—500 lbs. and over at one purchase, 3½c, 7c; less than 500 lbs., 7½c.

MANGANESE.—Per lb., \$2.75.

MAGNESIUM.—Pure, N. Y., \$1.60.

FIRE BRICK.—Domestic, carloads 1000, f. o. h., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skewback, \$30.00; circle, \$32.00.

FIRE CLAY.—Domestic, 3½ ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. h., factory, \$8.50.

## New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING MARCH 14, 1905.

781,728.—TABLE.—S. Astalos, Silverdale, Wash.  
781,976.—STEAM BOILER.—G. H. Blowers, San Francisco.  
784,918.—GARMENT.—M. Buesick, Phoenix, Ariz.  
784,984.—TOOL.—W. L. Carson, Seattle, Wash.  
785,035.—LOCOMOTIVE.—P. F. Dundon, San Francisco.  
784,995.—NEEDLE.—T. C. Edwards, Salinas, Cal.  
784,790.—BATTERY STEM GUIDE.—C. P. Hawley, Heppner, Or.  
784,676.—CARBURETER.—J. F. E. M. Hilscher, Fullerton, Cal.  
784,859.—SEWE.—M. W. Hunt, Portland, Or.  
784,665.—COMPENSER.—J. M. Keller, Los Angeles, Cal.  
784,689.—GAS BURNER.—Kistler & Symonds, Los Angeles, Cal.  
785,045.—BOOTJACK.—J. J. McDonald, Port Madison, Wash.  
784,586.—HOISTING DEVICE.—R. McGahey, Walla Walla, Wash.  
784,751.—SHOW CASE.—W. W. McKee, Tacoma, Wash.  
784,801.—CARPET CLEANER.—A. E. Moorhead, Oakland, Cal.  
784,855.—EXTRACTING ORE.—E. L. Priest, Oakland, Cal.  
784,808.—ENGINE.—C. A. Sawtelle, San Francisco.  
784,802.—FIRE FABRIC.—S. Scarles, Stockton, Cal.  
784,763.—SHAVING BRUSH.—Silverman & Vincent, San Francisco.  
781,710.—HOOK AND EYE.—G. G. Tandy, San Francisco.  
781,769.—HAMMOCK SUPPORT.—W. Vincent, San Francisco.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

SANITARY SHAVING BRUSH.—No. 784,763. March 14, 1905. L. Silverman of San Francisco, Cal., and Wm. Vincent of Oakland, Cal. The object of this invention is to provide a simple, practical sanitary brush which may be taken apart after each period of use, the bristles opened out and thoroughly cleansed and sterilized, and which permits the parts to be again easily assembled.

COMBINATION HAMMOCK AND CANOPY SUPPORT.—No. 781,769. March 14, 1905. William Vincent of Oakland, Cal. My invention relates to improvements in supporting means for hammocks, canopies, tent coverings and the like. Its object is to provide a light, collapsible and adjustable support of this character which can be set up quickly and made into a rigid structure or be knocked down and folded into a small compass convenient for carrying and shipment. It consists in the various details of construction adapted to bring about the required result.

REVOLUBLE EXPLOSIVE ENGINE.—No. 784,808. March 14, 1905. C. A. Sawtelle, San Francisco, Cal. Assigned to the Sawtelle Rotary Motor Co. of San Francisco, Cal., a corporation of California. This invention consists essentially of a plurality of cylinders mounted radially about a crank shaft and having the connecting rods of each extending from their pistons to a crank sufficiently distant from the crank shaft to insure the reciprocation of each piston in its cylinder as the cylinders are revolved around the shaft. The cylinders are connected with a central chamber forming a crank casing which is turnable upon the shaft and which casing has sleeves extending to both sides, through which the shaft passes, one of said sleeves carrying a gear engaging a similar gear and adapted to transmit power to the power shaft. The crank shaft also carries a gear and by the disposition of these gears both the crank casing and cylinders and the shaft are revolved in opposite directions when power is applied, and the motion of each will be transmitted to a power shaft or shafts.

## Cananea, Mexico.

The city of Cananea and its huge activities have sprung into existence "in a day," as it were. Five years ago the site of the present populous and prosperous town was merely a collection of adobe houses and rude Mexican huts. The accompanying illustrations convey some idea of the change which has taken place in this brief time. The great mines and reduction works are in the vicinity of the town. The holdings of the Cananea Copper Co. exceed 10,000 acres of land in this mineral belt, which extends southeastward into Mexico and northwestward into Arizona. The smelters are turning out millions of pounds of copper monthly, and the concern has become one of the most important copper producers in the world. The company owns a railway system connecting the most important mines with the smelters, and with the main line of railway to the northward. The town has all of the essential features of metropolitan cities of the sixth class in the United States; has numerous public buildings, handsome private residences, and other substantial improvements. The climate is fine, and there is no more healthful locality in the mines of the Southwest. The greater number of inhabitants not engaged in merchandising are directly connected in some capacity with the copper mines, reduction plant or the railway. Besides the holdings of the Cananea Co. the Copper Queen Co. of Bisbee, Ariz., has purchased a number of promising mining locations, which they are developing. There is gold and silver in the dis-

General View of the Town of Cananea, Mexico. (See Page 200).

trict, also, but the mines are chiefly valuable for copper. In the region lying to the westward of the Cananea mountains gold mines have been developed in a superficial way, but their richness has not, as yet, been of such a character as to attract much attention outside the district. Mining is carried on there in a primitive way, mostly by Mexican miners, many of whom make a livelihood by working the placers by employing various types of dry-blowing machines.

This section of Mexico is receiving an increasing amount of attention with each passing year. The copper mines of Nacozari are only a few miles distant to the southeastward, and are apparently on the same mineral belt with Bisbee and Cananea. There are also numerous other copper prospects which have been well spoken of, and the copper output from this part of Mexico gives evidence of being increased for some time to come. The ores of the district are both oxidized and sulphide. Much of the material is sent to the smelters direct from the mines, but the sulphide ores are concentrated and the concentrates sent to the smelters for further treatment.

Smelters and View of a Part of the Town, Cananea, Mexico. (See Page 200).

## "Reforms Needed in Mining."

As a class, mining engineers are proud of their profession, and they have every reason to be, for the mining industry is the basal industry of this country, the foundation upon which all other industries are built and, through it, maintained. This does not refer particularly to the business of gold and silver mining, but also to copper, iron, coal and all of the other varied branches of the great industry of mining.

Is the imputation made elsewhere (see page 202) by a correspondent true—that mining engineers have become apathetic and have shown little progress in making a substantial advance, and that the professional mining engineers have not kept pace with practical miners during the past thirty years?

An analysis of the situation fails to show that such is the case. Rarely have mining engineers undertaken to claim credit for that which they did not inaugurate or create. Nearly all of the advance in mining science is directly attributable to mining engineers.

In the contemplation of this subject the mining engineer must not be confounded with the promoter. The latter is quite a different personage, having usually little to do with the practical business of mining. It is the business of the mining engineer to carefully consider the best interests of his company, to equip the mine with proper machinery, to exercise his judgment in this and every other direction, and to produce the very best possible economic results with the available means under existing conditions. Mine managers are not all mining engineers, but this is written in reference to mining engineers, whether managers, consulting engineers or superintendents. A mining engineer will have the books of the mine kept in such shape that he may at any time ascertain the cost of doing any particular work, whether drifting, sinking, stoping, milling or whatever it may be. He should be, and usually is, a good judge of the amount of work men in the various departments under him should reasonably perform in a day. Having determined this quantity and demonstrated it practically he must see to it that this result is obtained. If the manager does not make it his business to look after these small matters they will probably not be looked after. When the cost runs up he demands an explanation of the foreman and shift

bosses. If a satisfactory explanation is not forthcoming there may be some changes in the staff.

There are those who may criticize adversely this method of running a mine, but it is not a subject for adverse criticism. It is a method applied in business of almost every kind where working people are employed. When the men accept employment it is with the unwritten understanding, without comment or agreement, that they will give their best energies to their work. A single laggard in a gang of men will spoil the whole crew, and often the summary dismissal of this undesirable individual will work an astonishing reform in the remainder of the crew.

The mining engineer does not lack inventive genius, or initiative. He may not be an inventor, in the strict sense of the word, but he is certainly quick to perceive that a given invention can be applied to advantage in or about a mine. The steam shovel was designed originally to excavate banks of gravel. Probably nothing was further from the thought of the original inventor than putting a steam shovel several hundred feet underground to handle rock, but the mining engineer has applied it successfully to this class of work.

The charge that since the invention of the square-set system nothing of consequence or value has been done by mining engineers is without foundation. It is true that the square-set system, as invented and perfected by Phillip Deidesheimer, in the Ophir mine on the Comstock Lode, at Virginia City, Nev., in 1860, was one of the most fortunate and valuable contributions to the science of mining that the world had ever seen. It made it possible to operate mines which could not be worked previously by any known method; but within the past ten years economic conditions in some mining districts have demanded that the ore bodies be extracted at less expense, and, the square-set system being too costly, methods of stoping and filling have been introduced at some mines, where less than one-fifth the timbers required by square-set method are now used, and the ore is successfully extracted without loss of ore or injury to the workmen. Notable instances are at the Homestake mine, South Dakota (described in the MINING AND SCIENTIFIC PRESS in the issues of March 5 and 12, 1904), and at the Broken Hill mines, N. S. W. (MINING AND SCIENTIFIC PRESS, July 18-25, 1903), and D. G. Del Prat mined underground a mass of iron ore several hundred feet in width in Spain without using any timber at all. Surely these results of mining engineers' versatility and application are worthy of consideration and credit, and the very thing suggested by the correspondent has already been accomplished, but apparently without his knowledge. The mining method adopted by Gardner F. Williams in the Kimberley diamond mine is unlike any mining methods elsewhere. It is simple and inexpensive and requires no timber; but this method is due to the peculiar conditions obtaining there and can not be employed in all cases.

The suggestion that the distance between levels be reduced from 100 to 50 feet is that of one unacquainted with the additional expense required to open a level in a mine, and it is owing to this expense that in many well managed mines the levels are being cut 150 to 200 feet apart, a greater rather than a less distance.

The "three problems which must be solved," as suggested by the correspondent, viz., 1, Abolishment of timbering; 2, Reform in the system of overseeing; and, 3, Installation of reduction works in the mines, are rather amusing than otherwise. The first has practically been solved and a broader application of the idea may be looked for. In answer to the second, it may be suggested that no system of overseeing which fails to get an honest day's service from workmen can, nor should it endure. The owners look to the manager to accomplish reasonably good economic results. The manager necessarily places the situation before his foremen and shiftbosses, and it is their business to see that the men do their work properly. Men will not usually attempt to take advantage of a shift boss or foreman if they know that these under bosses are practical men who fully understand what a day's work really is. There is no doubt that there are instances where the power of the under bosses is used in a tyrannical and unjust manner, but these instances are comparatively rare. If a man is an incompetent workman or is physically

unable to perform the duties required in his position, the "boss" will quickly discover it. He usually gives a friendly warning, which failing of the desired result, the offender is given a time check and sent to the surface. The third proposition, that reduction plants be placed under ground, is so impracticable and so devoid of common sense that no argument will be advanced against it.

The charge that shift bosses are placed in the mine principally owing to their qualifications as "fighting men" is untrue, with very rare possible exceptions. When the under bosses lack knowledge and experience in their work the miners can "soldier" ad libitum and the shift boss will not be aware of it. The only way in which shift bosses and other overseers may be dispensed with is by substituting the contract system. In this case every man has every other man on the job urging him to greater endeavor instead of but one as before, for all are now interested in seeing the best work done, that the profits may be larger for all.

The suggestion that the limitations of winding by single stage was reached, and overreached, at 4000 feet, is not substantiated by facts. There are a number of vertical shafts down below 4000 feet in the world, and at least two are within a few feet of a mile in vertical depth, and the loads are lifted from the bottoms of these shafts with a single winding and with apparent ease. That 5000 feet will mark the limit of depth to successful mining with single stage winding is not apparent.

The transportation problem deserves a word in this connection. Twenty years ago nearly all underground transportation was done by men who pushed single cars loaded with ore to the stations. Here and there was found a mine where a locomotive of some sort had been introduced to replace the trammer, and the cars were hauled from some central point in trains. Now nearly all large mines have either mechanical, electric or compressed air haulage plants in successful operation. All of these improvements are the direct result of the efforts and demands of the mining engineers and not of the laboring miners. These and many other mechanical devices, as well as improvements in the system of mining, have lowered the cost of mining step by step, until we see to-day mines successfully and profitably operated which would have fallen far short of it even a decade ago. The outcome is that work is afforded thousands of miners who otherwise could not be employed. It is not a fact that an increase in the wages results in an increase in the work of the miners. Good miners will seek the camps that pay the highest wages. This is true—and it is also true that these better workmen will crowd out and replace those who are their inferiors. This is the result of the natural adjustment of the conditions. The incapable miner gains little by an increase in wages, except under certain conditions where organization dominates common sense.

As to the relation of the mining engineer to fraudulent promotions, it does not concern him particularly. No mining engineer of good reputation will lend himself to what he knows to be a swindle, and his voice raised against it would fail to reach those who would fall victims to the wiles of the wildcat promoter. Technical journals stand in the same position exactly. The people who read the leading technical and mining publications are not those who are taken in by a fraudulent mine promotion. Without doubt the worth of a single upright mining engineer is far greater than that of any number of fraudulent promoters, but the prospective victims of the latter are beyond the reach of the former.

The overcapitalization of mining corporations is the result of the operation of financial directors, and cannot be charged to mining engineers. It is impossible to tell the value of a mine without a careful and exhaustive examination, not only of the mine itself, but of all the conditions having a bearing on its benefication. Mines sometimes exceed the expectations of their promoters and return more than was anticipated.

The communication on page 202 is apparently written in ignorance or defiance of plain facts. It is intemperate in tone and its strictures are almost wholly undeserved. To further comment upon it would probably be unnecessary to those who could understand it—and useless to those who could not.

## CONCENTRATES.

**NICKEL** occurs often in association with pyrrhotite, a magnetic iron sulphide.

**METALLURGICAL TESTS** of any kind should be made in a manner as closely approximating the treatment on a commercial scale as possible.

**TOPAZ** is associated with cassiterite at a number of places, known localities being Altenberg and Zinnwald, Saxony, and Mount Bischoff, Tasmania.

Two terms of mining leases should be clearly understood and reduced to writing to avoid future possible difficulties. If the lease is for a longer term than one year, it should be written in order to avoid the "statute of frauds."

**TOURMALINES** occur in coarse-grained granite (pegmatite) dikes. All tourmalines are not transparent. Some are black and opaque. This variety is known also as jet. The colored tourmalines when transparent are valuable as gems, and for optical purposes.

No secretary has as yet been appointed for the California Miners' Association to succeed E. H. Benjamin, who was elected to the presidency of the Association last December, and who is acting secretary at present. His office is at 331 Pine street, San Francisco, Cal.

**IRON AND STEEL TOOLS, RAILS, ETC.**, left in copper mines which subsequently become filled with water, often are replaced to a greater or less extent by copper, depending on the length of time the iron or steel objects remain in contact with the copper-bearing water.

The scouring of inside plates in stamp batteries may be reduced materially by placing over the plates a grating of either cast iron or heavy wire screen. This breaks the cutting and scouring force of the pulp splash and gives the amalgam an opportunity to accumulate on the plate.

The Printer Boy gold mine on upper California gulch at Leadville was the only quartz mine of consequence in operation in that district in the early 70's. The carbonate ores had not been discovered at that time. The ore was treated in a mill at the mine. The output was about \$8000 per month.

**MINING CLAIMS** are located and held in Alaska under the Federal mining statutes. Miners in any organized district of Alaska may make rules and regulations governing the recording of notices of locations of mining claims, water rights, flumes and ditches, millsites and affidavits of labor not in conflict with the general laws of the United States.

A **TURBINE WHEEL**, 56 inches in diameter, under a 13-foot head, will require 5250 cubic feet of water per minute, (about 3500 miners' inches) and will develop about 115 H. P., the wheel making 89 revolutions per minute. There would be no advantage in placing in the penstock either a larger or smaller wheel, as the former would run more slowly and the latter would not pass so large a volume of water.

An ore feeder cannot be allowed to run without attention. It has devices to regulate the feed fast or slow. It cannot be set and kept at one position with any probability of an absolutely regular feed being maintained unless the ore coming to it is uniform in size, character and amount of moisture. The stamp tappet is supposed to drop on the feeder rod when the ore is required, but feeders require looking after by the battery men.

The legalized ton is 2240 pounds avoirdupois, as fixed by the United States Statute (sec. 2951), but the ton in general use is 2000 pounds. Ores throughout the United States are weighed by the ton of 2000 pounds, and in some districts coal, also, is weighed by this standard, though in the anthracite regions of the East, at the mines, the ton of 2240 pounds is employed, but the retail trade is carried on on the basis of 2000 pounds to the ton.

A **RECENTLY** completed survey of the United States Coast and Geodetic Survey, which has extended from the Atlantic to the Pacific oceans, in which precise leveling was the most important feature, has established a discrepancy of 0.615 foot between the two oceans, the Pacific being the higher. It is thought the discrepancy is due either to an accumulating error in leveling or to inaccuracy in making tidal observations, which can only be done by taking the mean of a large number of observations.

**MONAZITE** is the principal mineral employed in the manufacture of the white mantles used on gas lamps. It was worth \$140 to \$150 per ton in 1903. Monazite varies somewhat in color, being light yellow to honey yellow, reddish, brownish, and yellowish green. It has a resinous to vitreous luster, is brittle and breaks with an uneven fracture. It is from 5 to 5.5 in hardness and is heavy, having a gravity of 4.64 to 5.3. It is found in

streams and is often associated with gold, though also found where there is no gold. It occurs in schists and granitic rocks.

**ELECTRICAL POWER** is now transmitted at a satisfactory commercial profit in California at an approximate pressure of 60 kilovolts a distance of 230 miles. It is assumed within possibility that electric power is susceptible of similar transmission, commercially, 500 miles if in sufficiently large volume—200 megawatts. It is of further assumption that when so transmitted in such stated bulk, it would be commercially profitable to use copper wire of such a diameter that there would be no dissipation of brush discharge though there were 170 kilovolts between them.

The proper consistency of the pulp in pan amalgamation can only be determined by experience. If the pulp be thinned too much with water it will be impossible for the miller to raise the quicksilver through the charge and poor amalgamation will result, a large percentage of values escaping in the tailings. If the pulp be too thick by reason of insufficient water, the mercury will be reduced to such a fine state of division that "flouring" will result and much of the mercury and amalgam will in all likelihood float away on the surface of the water, taking values with it. The latter is the worse predicament, as not only are the values in the ore lost, but the quicksilver as well. The "happy medium" must be determined by experience or experiment.

The question as to which is the better—to treat sulphides at the mine by chlorination or some other process or to ship them to smelters—should be determined by the relative cost of these two methods of treatment. The first involves the capital invested in plant and its deterioration, as well as the actual cost of handling, roasting, chloridizing, leaching and the various losses sustained, both mechanical and chemical, throughout the process. The latter requires the consideration of sacks and sacking, losses in transportation and cost of transporting to smelter, return and wear and tear on sacks, smelter charges, moisture charges, losses charged by the smelter, etc. The question should be easily settled by a comparison of figures. A large chlorination works should treat sulphides cheaper than a small one.

**ARSENIC** occurs sparingly in native state, and various arsenides occur widely distributed, but the principal ore of arsenic is mispickel (arsenical-iron sulphide). It may be considered as iron sulphide ( $\text{FeS}_2$ ) in which one atom of sulphur has been replaced by one of arsenic ( $\text{FeAsS}$ ). The ore is crushed in rock breakers as it comes from the mine, is then usually passed through two or more sets of rolls to reduce the mineral to fine powder, and then passed through a furnace—generally a horizontal rotary furnace like a Bruckner or White-Howell. The arsenic volatilizes and passes off in fumes which are condensed in a chamber and subsequently collected and refined. The presence of pyrite associated with mispickel is not disadvantageous unless occurring in so large amount as to make the percentage of arsenic too small to be commercially of value.

If the boiler water gives trouble by formation of scale, the first step in correcting this difficulty is by having an analyses of the water made by some one experienced in this line of chemical work. This chemist should also be able to advise the best combination to use to counteract the scale. Boiler scale is due to two things, the presence of some mineral or organic substance in suspension, or in solution in the feed water. Soda ash, which is an impure carbonate of soda, is often effective in removing or preventing the formation of an excessive amount of scale, particularly in waters containing sulphates of lime and magnesia. The soda ash is not seriously detrimental to the boiler, and, in fact, its presence is to be preferred to the scale resulting from the presence of lime and magnesia. An excess of soda ash causes foaming, and should be avoided.

**MOST** millmen clean the outside apron plates in quartz mills too closely when cleaning up. In many instances this is due to the demands of the office, but if it were realized that this close scraping of the plates is detrimental and is not offset by the additional amount of gold obtained as a result of the practice, it would in most cases be discontinued. After such a close scraping the plate is left in anything but the best condition to resume amalgamation when starting up the mill after the clean-up, and much time is wasted in unnecessary dressing of plates. This loss of time and loss of gold usually more than offsets the additional amalgam obtained by close scraping. Nothing harder than a hard rubber scraper should be used regularly on the plates. In most mills too little time is given to dressing the plates, and too close scraping of plates is a common practice. This is particularly the case in mills where the ore is low grade—just the place where the opposite policy should be pursued.

**PURE GOLD** is not so quickly attacked by chlorine as that which is alloyed with a base metal, as copper. In chlorination works there is usually a fixed time for contact of the ore with chlorine, but the progress of the formation of ter-chloride of gold can be determined by experiment (taking samples and assaying). In the works, however, it is customary to work somewhat by the result of experience on former charges. If it has been found that the charge is sufficiently gased at the

end of twelve hours, the succeeding charge will probably be given the same time of contact. Should it be found to require forty hours or more, this is the time given. Such methods often result in loss, for its success depends upon absolutely uniform conditions. The roasted ore must have received the same treatment; the gas must be of the same strength and volume, and the moisture should be the same, but in practice these conditions from one charge to the next are rarely attained with exactness, and the result is that the tailings from some charges are much higher than others.

The cost per cubic yard of hydraulicking gold bearing gravel is dependent on so many factors that it is impossible to give an arbitrary figure. These factors are chiefly character of gravel, whether free washing or cemented by clay, lime or other material, amount of water available for washing and the head or pressure obtainable; height of the available gravel bank (a high bank can be washed relatively cheaper than a shallow one. Another, and not the least factor, is the grade of dump available. Without good fall it is difficult and expensive to get rid of tailings. There are other matters to be considered, such as relative amount and size of boulders encountered, etc. Some hydraulic operations have been reported as making a substantial profit on material running as low as 6 cents per cubic yard. Dredgers of the largest size operate at about this cost per yard, and the capital invested in a dredging plant is usually much less than in a hydraulic mine and plant. In some hydraulic mining properties in California the cost of ditch systems alone has exceeded \$500,000.

TO DETERMINE the number of cubic feet required to make a ton of ore composed of lead and iron or copper and iron minerals in a gangue is difficult if the character of the ores is not given. An ore containing lead 60%, iron 15% and a limestone gangue would require, if the lead and iron be sulphide, about 5.1 cubic feet to make one ton. There would be about 1385 pounds of galena, 562 pounds of pyrite and 53 pounds of limestone. This is dry weight. If the ore be measured as it stands in the mine it would require somewhat more, owing to the presence of moisture. An ore containing 3% iron and 15% copper, if the copper and iron minerals be pyrite and chalcocopyrite, with a porphyry gangue, would require about 11 cubic feet to make one ton in place. A ton would contain about 110 pounds of pyrite, 870 pounds of chalcocopyrite and 1020 pounds of gangue. An ore containing 3.5% copper (in the form of sulphide) and 10% iron as pyrite in a porphyry gangue will require 10.6 cubic feet to make one ton. A ton will contain about 380 pounds of pyrite, 200 pounds of chalcocopyrite and 1420 pounds of gangue. Ordinary quartz ore with but 1% or 2% sulphide of iron or copper is usually figured at 13 cubic feet per ton in place.

The so-called open cut or glory hole method of mining is undoubtedly the cheapest that can be adopted if the topographical conditions admit of it. It is usually carried on through the medium of a tunnel run underneath the cut and connected with it by a raise; but the open cut system may also be employed where no tunnel to the surface is possible, the ore going through a drift or crosscut to a shaft to be hoisted to the surface, as at the Alaska-Treadwell mine. The limit to which open workings may be carried has never been determined. At the Kimberley diamond mines, South Africa, the work was carried on to a depth of about 500 feet. Great caves of rim rock resulted, which led to an abandonment of this method. If the sides can be kept at an angle which will prevent caves, there is no reason why open cut mining may not go much deeper than 500 feet. In such large excavations the principal source of trouble and danger lies in the storm water which falls and runs into the cut, though usually the latter may be prevented. In a region of abundant rainfall, this becomes in time a very serious matter, and has as much to do with the limitations of the method as the falls of rock from the sides of the cut. Where possible, it were better to work two or more cuts to moderate depth than one having such great depth.

THERE is often a misapprehension as to the meaning of the terms "bond" and "option," as used in connection with prospective transfers of mining property. A bond is a written agreement between two or more persons whereby one of the parties to the instrument agrees to pay to the other party a stated sum of money at a specified time, in consideration of some act on the part of the second party, (in this case the transfer of the property in question to the first party). From this agreement, neither the prospective purchaser nor seller can withdraw without the consent of the other. An option is of two kinds, "buyer's option" and "seller's option." In the case of the former, the seller must transfer a deed to the property in accordance with the terms agreed upon whether he feels disposed to do so or not. In the "seller's option," the mine owner is not bound to transfer the property unless he sees fit. In either case, there is usually a forfeit of some sort. In the case of the buyer's option, the seller usually receives a cash sum in advance, or at stated times earlier than the date of consummation of the contract, or he considers the development work, which may have been agreed upon between them, to be performed at the expense of the buyer, as a sufficient penalty. Under the seller's option, the seller usually puts up a cash forfeit to "bind the bargain."

### The Mines of Cananea, Mexico.\*

Cananea mining district is in the State of Sonora, Mexico, 40 miles southwesterly from Bisbee, Ariz. Here a mountain range rises out of the sandy desert plain, composed of a light-colored igneous rock, with quartzites and limestone uplifted on its mass at the western end of the range. These rocks have been deformed, crushed and sheared by great compressive stresses, and it is along the zone of fracture and shearing that the principal ore bodies of the district occur. One of the notable features of the mineralization is the great masses of limonite gossan which are found capping the copper deposits at the surface.

The ore deposits are chiefly on the north slopes of the range, the trend of which is northwest-southeast. The mineralization is confined to the southern part of the range, the zone running with the axis of the mountains.

One of the principal groups of mines of the Cananea Company is called the Capote. The Capote basin is illustrated in the accompanying panoramic engraving. The ore body here consists of a mass of crushed

the Puertecitos on the north, a distance of about 8 miles. These rocks do not all contain ore, but it occurs localized along favorable beds. This mineralization is especially great at the southeast end of the range. As the outcrops have been weathered and leached, they now form great ridges of gossan. The Democrata is the most easterly, and between this and the Capote vein there is the Veta Grande, a big iron vein, and a large number of small veins in the limestone series, while in the porphyry and quartzite to the west the Oversight and Capote mines are found.

The Capote ore body consists of a mass of crushed porphyry, altered to a white, clayey material, and carrying scarf-like masses, strings and bunches of soft, black copper glance, with some residual pyrite. The southwest and southeast parts of the ore body consist of a shattered mass of quartzite whose joints, fissures and interstices are filled by ore. This crushed material has all the characters of an inter-fault mass; but no boundary fault slips were observed, and, where the boundary of the ore was seen, the transition to solid and lean quartzite or pyritized porphyry was very abrupt. The evidences that the glance is of secondary origin are clear and conclusive, both in the faces seen in the mine and in thin

The ores of the different mines vary considerably in character and value. In general, it may be stated that the ore from the group of mines nearest the smelter, embracing all the bonanza mines of to-day, is quite siliceous, occurring largely in quartzite gangue or an altered quartz porphyry. The ore from the Puertecitos group is less siliceous, the gangue consisting largely of calcite and garnet. The intermediate mine, the Elisa, has a chalcopryite ore that is siliceous, but carries, I was told, good values of gold and silver. In the Veta Grande vein large bodies of low-grade ore were encountered carrying native copper in a very siliceous gangue. This ore will average about 2.15% copper, but also carries about .38 ounce gold per ton. It is this ore which can be so easily and advantageously concentrated—tests showing, I was told, a saving of nearly 92%, and the concentrates having 22% copper and 3.6 ounces gold per ton.

(TO BE CONTINUED.)

### To Search for Platinum.

Owing to the increased demand for platinum, the United States Geological Survey is about to make an

Panoramic View of the Mines in Capote Basin, Cananea, Mexico.

and altered eruptive rock, much of it changed to kaolin, through which is scattered grains, veinlets and bunches of copper ore, chiefly a soft, black copper glance. The normal ore is chalcopryite, but this mineral in the upper part of the vein has been altered into a variety of copper-bearing minerals—sulphides, carbonates and oxides. Native copper is of frequent occurrence. The ore deposits are thus described by W. H. Weed in the Transactions of the American Institute of Mining Engineers:

**THE ORE DEPOSITS.**—The ore bodies of the Cananea consist of great masses of chalcopryite (and its secondary products, glance, malachite, cuprite, native copper, etc.), occurring in the altered sedimentary rocks, and in veins or fractures in which secondary concentration has occurred. The contact bodies are not, however, confined to the immediate proximity of the eruptive mass and are, therefore, not of the true Kristiania type. The rocks consist of series of beds dipping east about 60°, the original bedding of the sediments being clearly recognizable, since original differences in composition have produced different mineral composition. This is especially well shown on the west side of the mountains, along the wagon road from Capote to the sawmill, and also along the road from Puertecitos to the Elenita mine.

There is a belt of these contact metamorphic rocks extending from the Cobre Graude on the southeast to

sections of the ore, where the disseminated pyrite grains (of an altered porphyry, forming a dike in the quartzite of the ore body) are partly replaced by glance. The ore body is very large, measuring 275x135 feet on the 100-foot level and 165x100 feet on the 200-foot level. The ore is soft, as much of the porphyry is rotted; heavy timbers in square sets are used and the space filled with waste, as in the Butte practice. Much of the ore will run 15% as mined. In the rock cuts along the narrow-gauge railway the true nature of several of the lesser veins is recognizable as altered strata impregnated with chalcopryite, with small amounts of galena and blende.

In the Cananea district the vein outcrops are the most prominent features of the landscape in the vicinity of the mines now being worked. The enormous masses of iron ore, the gossan caps of the veins, form high ridges of rough, brown rock, traceable for long distances across relatively smooth slopes. Where the streams have cut across these vein outcrops, the deep and narrow gorges show excellent sections of the veins and the enclosing rocks. It is in such places that the earliest mining was done. The drifts and tunnels driven in the veins disclosed large masses of native copper, carbonates and oxide ores, the existence of which made the region well known throughout Sonora for the last half century. As the gossan cap is penetrated, the ore beneath is found to consist of pyrite and chalcopryite, mixed with much earthy and soft black copper glance.

examination of the platinum resources of the United States. It is proposed to collect the heavy sands from all placer mines in the United States where evidences of platinum have been observed. The samples thus obtained will be used in determining the best methods of extracting the various minerals which have economic value. It is hoped that the separation and sale of these useful minerals, such as magnetite, chromite, garnet, monazite, rutile, zircon, gold, platinum, etc., will, in many places, become a permanent and profitable industry. As a preliminary step to this investigation, the Survey invites the owners of placer deposits to contribute for examination samples of material likely to contain platinum. These samples, which should be sent by mail, must weigh not more than four pounds each. It is suggested that the gravel be concentrated before it is mailed. Careful note should be made on the package, or in a letter accompanying it, of the total quantity of original gravel which the concentrate represents, in order that an accurate idea may be obtained of the value of the gravel for the purposes under investigation.

Each package of sand should be accompanied by exact information as to the name and postoffice address of the sender, the name of the mine or claim from which it came, and the State, county, city, village, or district in which the deposit is located. It is desirable that the owner of each deposit should state what efforts have previously been made to sepa-

\* See illustrations front page.

rate platinum from his sand or from other sands in his neighborhood.

After the Survey has made an examination of these samples, experts will be sent to all localities where preliminary tests give evidence of platinum. The expert will report on the size of the deposit and superintend the collection of representative samples for concentration. Experiments in the concentration of platinum sands will probably be carried on in connection with the exhibits of mining machinery at the Lewis and Clarke Centennial at Portland, Or., between June 1 and October 15, 1905.

As a help to prospectors, the Survey publishes the following facts about the qualities of platinum:

Pure platinum is a silvery white metal with a specific gravity of 21.5. With the exception of iridosmium it is the heaviest metal occurring in nature. It is almost as hard as iron and is very malleable. Platinum does not amalgamate with quicksilver, is not dissolved by potassium cyanide when cold, is not attacked by acids, except the mixture of nitric acid and hydrochloric acid known as aqua regia. It is more difficult to melt than gold.

Native platinum has been found most frequently in gold-bearing sands. On account of its weight it remains in the sluices with gold and other heavy material. It is most readily distinguished by the

has been detected by assay in sands from Lancaster and Montgomery counties, Pa. The richest producer of platinum in the United States is the Rambler mine of Albany county, Wyo.

**The Cost of Bailing.**

Mine drainage is one of the most important factors in the expense of operating a wet mine. There are many mines fortunately situated in this regard which may be drained by means of tunnels, which, having been driven, the drainage problem is no longer a source of expense. The greater number of mines, however, are less fortunately situated, and the water must be raised by pumps, skips, hydraulic elevators, or by air devices. In the selection of a method for handling mine water there are many things which require careful consideration. Pumps are so various in design, efficiency and cost of operation that it is not always an easy matter to decide. The expense of power is one of the chief considerations, but in recent years, in many districts, the power problem has been simplified and its cost reduced by the introduction of electricity. Many mining districts, situated where fuel of any kind is expensive, and power accordingly high, have been greatly benefited by the

of a new vertical shaft through the hanging wall country rock some years since, and practically all the water of the mine is now raised by a large skip through this shaft.

The shaft here referred to is nearly 1400 feet deep, the water being hoisted from 1360 feet. The skip is made of steel plates and angle iron and has a capacity of 1500 gallons. The amount of water raised in twenty-four hours is 250,019 gallons, this being the daily average during 1904. The cost of power is \$10 per day; engineers' wages \$3 per day. There are three engineers employed, but the superintendent, L. W. Shinn, states that but two engineers would be required if no water were hoisted, consequently the services of but one engineer is charged to water hoisting. The cost of repairs is about \$500 per annum, principally the cost of a new cable once a year, which has been the average during the past five years. No charge has been made for depreciation, that item having been small and covered by repairs.

Nearly all the men and tools are handled on this water skip, and this service more than pays for any depreciation. No interest charge has been included in this cost of hoisting water, but if it were placed at about one-third of the interest on cost and depreciation of hoisting plant the total cost of hoisting 250,-

Panoramic View of Mines in Capote Basin, Cananea, Mexico.

following characteristics:

(1) Its great weight. In panning it remains behind even gold in the pan.

(2) Its white color. It is whiter than lead and is distinguished from amalgam by its smooth surface, whereas the surface of amalgam as seen under a good glass is rough.

Native platinum is usually very impure; occasionally it contains so much iron and so many other impurities as to be dark in color and not easily distinguished from chromite, with which it is commonly associated. It frequently contains iridosmium, which occurs as flat, angular scales, while platinum grains are usually rounded, like gold dust. Platinum nuggets are usually smaller than gold grains. Large nuggets are very rare.

Platinum seems to be more generally distributed through California than through any other State. It has been found in Butte, Del Norte, Humboldt, Mendocino, Placer, Plumas, San Luis Obispo, Santa Barbara, Santa Cruz, Shasta, Siskiyou, Tehama, Trinity and Yuba counties. Curry, Coos, Lincoln and Josephine counties in Oregon have produced platinum. It has been discovered in Nez Perces county, Idaho. A nugget of platinum was found in Rutherford county, N. C., in 1847, and one in Clinton county, N. Y., in 1880. Platinum has been reported from Custer county, Mont., from Lumpkin county, Ga., and from the beach north of Lituya bay, Alaska. It

introduction of electric power, transmitted from a distance. This is the case on the Comstock Lode at Virginia City, Nev., where the introduction of electricity has reduced the cost of power from \$20 per horse power per month to \$7. There are many other similar instances where a greater or less saving has been effected. The power problem, however, is only one factor to be considered, for where mines are drained through shafts by pumping or bailing power must be employed. And this is also the case where the air lift is employed, for power is required to operate the air compressor. In the case of the hydraulic ejector the water used under high pressure is equivalent to a power, in some cases, sufficient to operate a pump of a capacity equal to that of the ejector.

In considering the matter of mine drainage it is always interesting to have responsible figures representing the cost of raising mine water under stated conditions, for the purpose of comparison. In many California mines drainage is accomplished by means of skips, operated either alternately, with ore skips, or continuously. The Utica mines at Angels, Calaveras county, Cal., is one of the most extensively developed mines in the State, and is operated wholly through shafts. In the old shafts at the north end of the property the water has always been handled by skips, though at the Stickle shaft a pump has been in operation for many years. The more extensive development and operation of the mine required the sinking

000 gallons of water daily from a depth of 1360 feet would fall well within \$20 per day.

In this connection the following is of interest to those who are giving attention to the subject of mine drainage. The figures are from an article by A. H. Goff in The Engineer:

RATIO OF WATER TO AIR REQUIRED.					
For Lifts Not Exceeding					
25 feet	2	volumes of air to 1 of water.			
50 feet	3	volumes of air to 1 of water.			
75 feet	4½	volumes of air to 1 of water.			
100 feet	6	volumes of air to 1 of water.			
125 feet	7½	volumes of air to 1 of water.			
150 feet	9	volumes of air to 1 of water.			
175 feet	10	volumes of air to 1 of water.			
200 feet	12	volumes of air to 1 of water.			
VOLUME OF FREE AIR, AIR PRESSURE, SUBMERGENCE AND HORSE POWER.					
Lift, Feet.	Submergence, Feet.	Air Pressure.	Free Air Per Minute, Cubic Feet per Gallon.	I. H. P. Per Gallon.	
25	38	17	0.3	0.0184	
50	75	33	0.4	0.0428	
75	113	49	0.6	0.0828	
100	150	65	0.8	0.1320	
125	188	82	1.0	0.1910	
150	225	98	1.2	0.2544	
175	263	115	1.4	0.3150	
200	300	130	1.6	0.3808	

For the proper working of an air lift a certain

amount of submergence is necessary. For the most economical and efficient results a submergence of 60% should be used—that is, 60% of the total length of the water discharge pipe should be below the water level in the well when pumped to its full capacity. For instance, let us assume that in a well 200 feet deep when pumping the water sinks to 40 feet below the surface of the ground, and it is desired to lift the water 20 feet above the surface of the ground. This gives a length of pipe 60 feet to the water level in the well, and as this does not include the submerged part of the pipe it is only 40% of the total length of water discharge pipe; the total length will, therefore, be 60 feet plus  $\frac{1}{2}$  times 60, or 90 feet submergence, making a total length of 150 feet of water discharge pipe.

It is not safe, unless under very favorable conditions, to figure on raising the water by the air lift system more than 200 feet above the lowest water level in the well. Nor is it always safe to extend the horizontal discharge more than 500 feet, as the air lift is not adapted to pumping horizontally to any great distance, unless reinforced by a pneumatic direct pressure pump, or an ordinary piston pump, either of which, however, could be operated by compressed air from the same pipe that supplies the well.

Suppose, for instance, that it is desired to lift 120 gallons of water 100 feet high per minute. It will be seen by the above table that this will require 150 feet submergence, thus making 250 feet of water discharge pipe, sixty-five pounds air pressure, 96 cubic feet of free air per minute and a compressor developing 15.84 H. P.

### Reforms Needed in Mining.

TO THE EDITOR:—An impartial, impassionate review of the mining profession, one embracing disinterested but decisive criticism, can not fail to be productive of much benefit, though it may bring forth bitterness. This is because the profession has not been subjected to thorough investigation. While it needs improvement, and radical reforms, it remains apathetic, unappealing and almost paralyzed. It shows little progress. This is not attributable to lack of affection of mining engineers for their profession or to their dearth of interest in exalting it, it being certain that it inspires in them boundless enthusiasm. On the contrary, the immobility of the profession is more likely due to the excess of enthusiasm of some of those devoted to it, rather than want of it. Very likely the marvellous advance of the mining industry has created a form of fanaticism among mining engineers and this, falsely identified with superfluous ardor, has blinded them so that they are unable to act as they should. But it is too true that they have not kept pace with miners for the past thirty years and that their profession has remained dormant or inert, while the industry which they are supposed to guard and govern has made extraordinary progress.

Mining engineers have been accustomed to appropriate most of the credit for the magnificent development of mining during the past thirty years. They have no right to do this, but in doing so they do less wrong to those from whom they wrest that credit than to themselves. The law of compensation causes the boomerang to recoil and in this case it has come back to strike the mining profession. Resting upon the laurels which they unrighteously pluck from the brow of the mining industry, mining engineers have suffered a serious setback which appears retrogressive. They have allowed the industry to go ahead of them with such strides that their cherished profession seems to be left standing still, if not falling backward. Their excessive enthusiasm has degenerated into devout meditation and the result is that their profession suffers from the results of indolence, the greatest defect it could have, and not from conservatism, which is a quality slightly known to it.

No other industry so depends for its purity and progress upon its high priests as mining does, in this epoch, especially. Many owners, operators and manipulators of mining property devote themselves too much to schemes for reducing wages of their employees and swindling of unsophisticated speculators. Law is powerless to protect mining from the scoundrels who befoul it. All depends upon the mining engineers who sometimes sleep at their posts. It is time that they be aroused to duty.

One cause of the apparent lack of inventive genius in the mining profession is facility to earn money in it, combined with indifference of mining engineers as to the methods pursued by operators to interest the public in their schemes. Some mining engineers are absolutely averse to invention. Perhaps if rewards were in sight they would exert themselves. Inventors in other walks of life do not keep gain so much in view as those in the mining profession. They do not make so sure of the commercial value of the products of their brains as mining engineers do. For this reason it seems that not until the ingenuity of other callings is exhausted can that of the mining profession be expected to develop. Up to date, nearly all machinery and systems in mines have

been invented by persons not so intimately connected with the mining industry, and evidently mining will depend for some time on outsiders for inventions advantageous to it.

Important inventions by mining men, properly so-called, are indeed rare. It is forty-five years since the square-set system of supporting undermined earth was invented. Since then nothing of equal value has come forth from mining engineers. That system itself exemplifies the barrenness of invention among professional mining men. It is primitive to such a degree that it appears to have no original. It exposes mining to the charge of being in its infancy. No sensible person, whether familiar with, or ignorant of, mining, can fail to question why a forest should be transferred to the bowels of the earth and there erected in multiquadrangular form for the simple purpose of preventing caving. Some other system far more simple could have been thought out as a substitute, not to avert caving, but to dispense with timbering.

The only offset to the square-set system, namely, the open cut or removal of ground, which would otherwise be left overhanging and likely to subside, in order to evade the necessity of timbering it, shows how cumbersome are the methods of and how unimaginative are mining men. As loss of ores through caving of ground is easily avoided and the only real objection to caving is founded on the peril to miners, it is evident, even to the uninitiated, that some system as simple as the design of a bicycle, but infinitely superior to squaresetting and overhang cutting, could be invented. If the supporting of masses of great weight was not peculiar to the mining industry and, therefore, does not call the attention of men not intimately identified with that industry, there is no doubt the invention suggested would have come forth long ago. Perhaps the mining world would not be willing to change the level system, now, as a general rule, necessitating stations every 100 feet, although the reduction of the distance between stations even to 50 feet would not involve much additional expense, even in old mines, while the effectual economy would send the industry ahead many revolutions simply through the removal of an uncalled-for burden.

Three extraordinary problems must be solved before any advance worthy the name can be made in mining. These are:

1. Abolishment of timbering.
2. Reform of the system of overseeing.
3. Installation of reduction plants in the mines.

Enough has been said of the first. The second calls for investigation with increasing emphasis day by day.

The system of overseeing is absurdly antiquated and quaintly inutile. It could advantageously be abolished without a substitute being supplied for it in advance. Like the system of 100-foot levels, it is sustained almost entirely by superstition in conjunction with the lack of initiative of mining men. It is a case of "as it is with us so it was in the days of our fathers and so it will be with our sons."

As a rule, "shift bosses" in mines are hired bullies. Having no more actual knowledge of and experience in mining than the toiling miners, they are placed in positions as overseers simply because of their domineering abilities. Miners who have earned reputations as pugilists are usually selected as shift bosses, at least in Australia, South Africa and the Rocky Mountains. Indeed, shift bosses boast more of their prowess as sluggers than of their ability as miners. They are employed, not to direct and aid miners, but to intimidate them.

Modern miners are of too high intelligence to require the dominating supervision of overseers who cannot boast that they depend on their skill for their positions. Miners, especially those of the United States and Australia, will not give to the exacting shift boss what he expects. Molested, they rest on their machines. It is the overseer who shows his authority least that secures the best results from the operator, but such a boss is not appreciated by his employer. The latter, blinded by the superstition that shift bosses are indispensable, expects that the more progress a miner makes the more he can be made to make by the urgings of the boss. Nothing could be more erroneous. The intelligent shift boss, exception though he be, knows that as a shift boss he is superfluous and, therefore, shows himself as little as possible to those subject to him. Miners feel as though they are considerably treated by the overseer only when the latter keeps out of sight. They are irritated by his visits, for each visit means so much loss of time to them. Even if they worked better with the overseer present than when absent, the latter would not be earning his salary, since he cannot devote more than half an hour of his time to each miner under him. But miners know what a "shift's work" is, and they usually accomplish it. The presence of the boss does not affect their exertions.

An overseer is necessary only for miners of little experience, and it is a curious mine in which there are enough inexperienced men to require an overseer. The skilled miner needs no boss. He is superior to his overseer. He knows better than any boss his machine, his ground and his duty. The less boss the more miner.

The abolishment of the system of overseeing, without any substitute being furnished for it, might disturb matters. If a substitute can be found, such as a monitor system, well and good. A complete reformation should be easily brought about.

Nearly ten years ago I suggested that reduction plants be installed in mines instead of on surface. Up to date the suggestion has not been acted upon. This is because of lack of initiative among mining men. No invention is necessary to effect the reform proposed. Inaction is the cause of its being neglected. However, another ten years cannot pass without steps being taken in the direction pointed out. This is not because mining men wish to avoid the unnecessary expense involved in hoisting material from great depths to the surface. They prefer the extravagance of old methods to the risk of innovations. But when the tensile strength of steel cable is exhausted they must, perforce, place milling and smelting plants well down within the bowels of the earth.

In a few years the leading mines of the world will be too deep for operation through a single section of shaft. Some shafts have reached depths of 4000 feet. Steel cable cannot be used to hoist loads from much greater depths at a single winding. The margin of safety has already been excessively encroached upon. It would be criminal to hoist men from a depth of 5000 feet with a single length of steel cable. When such depth is reached in a mine a hoisting plant must be placed below, especially if the earth is to be penetrated to still greater depths. Then the mill or smelter must be introduced into the mine, since it would be the height of folly to hoist ores to the surface.

The innovations suggested in this article would work hand in hand. The caving system would be aided by the slimes and slags made available by the proximity of the reduction plants, if requiring aid. Cost of mining would be reduced fully 30%.

Such economy as could be effected in this way is not only legitimate and just, but magnificent as well, as compared with such retrenchment as reduction of wages, which is often considered the great desideratum among mining men. Saving money at the expense of miners is not only iniquitous, but preposterous. Something nobler must be inaugurated. Methods of economizing labor without reducing wages should be brought into vogue. A mining man who schemes chiefly to cut wages is inefficient.

It is questionable if wage lowering ever effects economy. A 10% fall in the price of skilled labor of miners invariably results in a 5% diminishment of their usefulness. There are no workingmen who appreciate good treatment by employers as much as the American and Australian miners, and yet they resent bad treatment more than any other laborers. They guard vigilantly their own rights and respect the rights of employers who are just toward them, but they will shirk, and botch, and steal ore in mines belonging to those who would reduce the narrow margin between them and want. Moreover, the danger of strikes through lowering wages more than offsets the slight showing of economy which may be left after the permanent diminishment in the standard of efficiency of miners.

There is but little doubt that the increase of wages of miners results advantageously to operators, at least in districts where there are competing mines. Antagonism among mine owners which brings about increases of wages for their employees is far more praiseworthy than co-operation to cause reductions. This is not only because of advantages bestowed on the miners, but because of benefits reaped by the employers as well. A 10% increase in miners' wages is always followed by a 5% improvement in their efficiency and, what is more, an avoidance of strikes and friction.

No men earn their living so worthily and with so many personal sacrifices as miners. They are more subject to the sweating process, are more liable to dangerous illnesses and have more uncomfortable surroundings than any other class of men. While disposed to suffer from terrific headaches following the handling of dynamite, they have the sword of Damocles constantly hanging over them.

The mining profession requires men who are superior in intellect to those who have the sordid desire to reduce wages. Mining engineers should devote themselves to searching for methods to save labor in the interest of humanity and to increase wages in the interest of industry. Working underground, under prevailing circumstances, is no fit way for a human being to gain a livelihood and, consequently, every invention which takes men out of the mines is humanitarian and every increase of wages exalts the mining industry, in that it raises the efficiency of miners and encourages invention among them and among mining engineers as well.

After all, the principal charge against mining engineers is that of criminal neglect for having permitted so many frauds to be perpetrated in the name of the mining industry and for failure to attempt to prevent more from being committed. It is entirely within the province and easily in the power of mining engineers to block the unscrupulous exploiters who invade the mining field. Governments can do nothing to protect the investors. In this age of graft they have all they can do to protect themselves against thieves. It is so easy of accomplishment by mining

engineers that it is surprising that scoundrels are not expelled from the mining fraternity. The policy of "leaving the other fellow alone" must be discarded. The "other fellow," the fraudulent promoter, must be forced to the wall so energetically as to break every bone in his body and afterward his body must be trod upon until it shall have mixed with the mud and disappeared. There is no more contemptible thief than this fellow who can not be reached by law, but can be gripped by the mining profession.

One upright mining engineer should outweigh a million dishonest promoters, but he doesn't, simply because investors do not know how to regulate the mining scales.

The most abominable swindles are those committed through the medium of properties in Australia, South Africa, Mexico and the United States.

But it is a mere question of methods. Mining engineers are fearful of the libel laws when there is really no need of fear. The truth about any mining swindle can be established before application of the libel laws can be made.

Frauds committed in South Africa have been of such magnitude that they should have been apparent.

Through Mexican mines Americans have been swindled year after year. Saltieg is extensively carried on. Proprietors of claims hundreds of miles distant from genuine discoveries inform the public that those discoveries immediately adjoin their holdings.

Coal is scarce in Mexico, selling for \$15 per ton. Discoveries of fuel cause excitement and wild speculation. Unmarketable lignite and worthless obsidian are exploited. The fakir sends to Pennsylvania for specimens of good coal, has them assayed in the City of Mexico as samples from his Mexican "coal" lands, flourishes the certificate of assay to prospective victims, and sells shares, and the investors never even suspect.

Dozens of mines deserve to be closed as much as dens of counterfeiters. The greatest crime committed through them is the leading astray of labor. Armies of miners delve in worthless properties. Their energies are diverted fraudulently from other walks of life. As all labor should be productive, a direct violation of the laws of humanity is done in this way. Society may excuse the existence of millions of soldiers, but mankind cannot afford the unwarranted waste of labor involved in the false utilization of the toil of miners. In these days, when cost of living constantly increases, every worker should be a producer. Promoters of wildcat mining companies not only rob the honest investor, but seduce the healthy toiler—the toiler who earns his living by contributing to the general welfare. Mining prostitution of labor is the foulest of all prostitutions, and must be stopped. It is the final step in the debauchery of industry.

Too often does the young mining engineer, in his eagerness to secure a start in his career, take unclean risks, such as those involved in the management of wildcat mines. He depends upon a rotten branch to suspend himself over a precipice. His fall is almost certain. And there is no necessity for it. A longer course in ethics in school would convince him of this. But, at all events, it is better for him to abandon his profession than to seek to follow it in the manner mentioned.

I make these suggestions believing mining to be too great an industry to be subjected to exploitation by scoundrels, and of too bright a future to be held back by lack of invention and initiative on the part of those whose duty it is to keep it advancing. Mining is now at the stage when it must give up its policy of slight variation and slow transformation. Reformation must be undertaken. Infancy will no longer serve to excuse its faults.

City of Mexico, March 25.

JOHN DWYER.

## THE PROSPECTOR.

Fluorspar may be either white, colorless, blue, green, pink, or other colors due to iron and other oxides. It may be either transparent, or sub-translucent. The streak is white whatever the color. It is above the average in specific gravity, being 3.01 to 3.25. Quartz may be compared, being 2.6. Barite is heavier, being 4.3 to 4.6. Fluorite is comparatively soft, having a hardness of 4, easily scratched by a knife. It commonly crystallizes in cubes or some modified form of the cube. It does not effervesce with either hydrochloric or nitric acid, but is attacked by sulphuric acid with the formation of hydrofluoric acid, which will etch glass.

The mineral samples from Humbug district, Yavapai county, Ariz., are wolframite, a tungstate of iron and manganese. The mineral is valuable for the tungsten which it contains, which is used in steel making.

The mineral from Bearmouth, Mont., is a crushed and sheaved greenstone, now altered to talcose and chloritic material. It is what might be termed the "gouge," "vein matter" or "cab" (Cornish) of the vein. It contains iron sulphide (pyrite). Material

of this character is not infrequently gold bearing, but is generally low grade. It should be assayed for gold. This "The Prospector" cannot undertake to do.

The rock specimens from Graniteville, Cal., are: No. 1 is quartz, containing a very small amount of sulphide (iron and copper). No. 2 is quartz, to which is attached on one side a remnant of siliceous tale schist, from the wall probably. This specimen contains sulphides of iron and copper. The iron is light yellow, the copper dark yellow (chalcopryite), a small amount of bornite is also present (a dark purple-blue sulphide of copper). No galena can be seen, but there are a few scaly crystals of a mineral of lead or galena color, which are probably nagyagite, a telluride of lead, silver and gold. Both samples are probably gold bearing.

The mineral from Yreka, Cal., having a black color and submetallic luster, with bright green scales and veinlets distributed through it, is chromite, commonly known as chrome iron. It contains, when pure, chromium sesquioxide 68%, iron pentoxide 32%. The specimen is a good, clean ore of chrome. If the ore is situated where it may be cheaply mined and shipped it may net the owner a few dollars per ton. The value in New York is about \$15 per ton. The low price is due to the large importation of foreign ores on which there is no duty.

The rock from Piru, Ventura county, Cal., is an altered greenstone, now mostly chlorite, containing magnetite.

## Grading Analyses.\*

NUMBER II—CONCLUDED.

Written by H. S. DENNY.

The differences are hardly appreciable, and show that the work has been carefully done, and that there has been very little variation in the nature of the ore or in the screens used. It will be noticed on examining the values of the different grades before passing the plates that the poorest in every case is the coarse mesh—that is, the product remaining on the 60 mesh—which varies from 3.6 to 4.9 dwts. per ton. The richest is the percentage passing through 150 mesh and remaining on 200 mesh. After passing the plates the pulp is divided into slimes and sands, and it is interesting to notice what has happened to the various products. The first point that strikes one is that there is practically no extraction by amalgamation in the product remaining on 60 mesh. In the month of August it shows slightly higher in the sands charge than in the screen sample, but taking it throughout it remains the same. The product remaining on 100 mesh with an average of about 8.34 dwts. in the screen sample shows a value of about 3.82 dwts. in the sands charges, meaning in effect that about 57% of its contents has been extracted on the plates. The product remaining on 150 mesh, averaging 17.2 dwts. in the screen sample, is reduced in the sands charges to 3.74, representing 78.3% extraction by amalgamation. The percentage remaining on 200 mesh has a value of 19.22 dwts. in the screen sample, and is reduced to 3.28 dwts. in the sands charges, showing an extraction of 82.95% by amalgamation. The portion passing 200 mesh shows a value of 10.3 dwts. in the screen sample, and is reduced to 5.16 dwts. in the sands charges, showing an extraction by amalgamation of 50%. These are interesting figures, and they clearly point to the fact that the finer the sands the better the extraction by amalgamation. They also show that the portion passing 200 mesh, consisting probably of partly argillaceous slimes, does not show such a good extraction by amalgamation as the fine sands remaining on that screen. The next comparison is between the residues from the sands charges and their originals. It will be noticed that the highest value in the originals is in the percentage which passes the 200 mesh, all the other grades being lower and fairly uniform in value. Coming to the residues, we find that from an average value of about 3.85 dwts. in the charge remaining on 60 mesh the average residue is about 1.27 dwts., the average extraction, therefore, amounting to about 66%, while in the product passing 200 mesh from an average value of 5.16 dwts. we get a residue of .53 dwts., representing an extraction of about 90%.

Here, again, we have an illustration showing that our fine product is in a condition to rapidly yield its gold, and although the portion which passed 200 mesh in the screen sample did not show a very high extraction by amalgamation, it clearly proved to be very amenable to the subsequent cyanide treatment, yielding a very high percentage of extraction. Thus the portion remaining on 60 mesh in the screen sample shows an extraction in the joint operations of amalgamation and cyaniding of only about 66%, while the portion remaining on 200 mesh, showing an original average value of 19.2 dwts. as against .28 in the residue, gives an extraction of over 98%, representing an improvement of 32% in favor of the latter.

It is quite obvious, therefore, from a study of these

figures that the product remaining on 60 mesh is not in a condition to yield its gold to either the amalgamation or the cyanide processes, and that, therefore, it should be reduced further in order to give extraction more nearly approximating that won from the product remaining on 200 mesh.

The one point that requires some explanation is that the product passing through 150 and remaining on 200 mesh gives a better extraction (98%) in the joint processes than that passing through 200 mesh (about 95%), and this I can only ascribe to the presence of clayey matter—that is to say, the separation of sands and slimes is not so efficiently done as it might be. A study of this point led me to go carefully into the capacity of our sands plant and spitzkasten separators at the Van Ryn, and there is no doubt in my mind that the cause of this percentage of slimes in the sands is, first, inadequate capacity in the spitzkasten; second, incapacity in the tanks; third, inefficient flood gates in the settling tanks.

The above remarks are, I think, sufficiently full and clear to support my contention that the grading analysis is full of most important information in regard to the work being done right through the treatment plant. It has shown, firstly, what can be done by amalgamation, and what product is best suited to amalgamation; secondly, what product is unsuited to amalgamation; thirdly, the product best suited to the ordinary cyanide treatment, and that most unsuited; and fourthly, where losses are being made and why they are being made, and indirectly points to the possibility of largely decreasing capital expenditure in the cyanide plant owing to the reduction in the required time of treatment, and I submit that a simple analysis such as this is, that can afford such extensive and important information, is one that should not be neglected on any mine.

Similar analysis sheets were also prepared for the Meyer & Charlton, the New Goch, and the Roodepoort United Main Reef companies, which bear out the same conclusions to a greater or less extent. There are some interesting comparisons as between these mines, but those comparisons are hardly part of the subject matter of this paper. The variations are of more interest to the companies concerned than to this particular discussion. I must point out that in the case of the New Goch, concentration is resorted to after the pulp leaves the plates, and this fact must be borne in mind in analyzing the results on that mine.

**GENERAL CONCLUSIONS.**—The obvious conclusion from a study of the figures given under the last head is, that as the "coarse" particles are the poorest in the screen assay and the richest in the residues, as opposed to the "fine" particles, which are richest in the screen assay and poorest in the residues, there is a necessity for an alteration in our present methods of reduction. I do not wish to labor the subject of fine grinding, of which so much has been heard recently, but the only conclusion which one can draw from the figure given is, that the coarse production should be separated out and reduced to a mesh, somewhere between 150 and 200. The immediate result would be increased extraction in the cyanide works; against which, however, must be set the cost of regrinding.

Another point of very considerable importance is that to-day, in the attempts to get good extractions from the coarse particles in our sands plants, we are giving an average treatment of some six days. If there were no coarse particles—that is to say, if everything were reduced to a mesh between 22,500 and 40,000, it is more than probable that the six days' treatment could be reduced by 50%. The important bearing such a possibility has on the capacity required and the initial outlay involved in a modern sands plant demands your most careful consideration.

To-day, I believe, the majority of mining engineers are agreed that fine grinding must be resorted to. There is some division of opinion as to whether the whole of the fine product will then be treated in one operation or whether a classification will still be made of sands and slimes, and only work on a large scale on the two lines indicated can determine which is the more suitable method. Personally, I lean to the one-production-one-treatment proposal, but the pros and cons of this problem may more suitably be dealt with at a later date and under another head.

Finally, I think the grading analysis has shown that certain alterations in our treatment practice are not only desirable but necessary. The metallurgical difficulty has been clearly indicated, and shows where the trouble lies, and it now remains to provide an efficient and cheaply maintained grinding machine and a simple continuous treatment apparatus by virtue of which we shall, firstly, reduce our ore to a fineness consistent with high extraction, and secondly, continuously and economically separate our treated products from their gold-bearing solutions, leaving only the smallest value in our discarded residues.

It seldom pays to mix rich ore with poor, even when the lower grade material pays a profit. It is usually more profitable to treat each grade separately, as the large volume of low-grade material handled with the smaller amount of high-grade rock is likely to cause heavy mechanical losses in the latter.

\* Abstract Trans. S. A. Assn. Engrs.

## An Undeveloped Country.

Written for the MINING AND SCIENTIFIC PRESS by F. S. DAVIS.

Lying just south of, and adjoining, one of the richest and most progressive States in the Union, the peninsula of Baja (Lower) California is one of the least developed countries of its size known to mankind.

Yet this peninsula was one of the first known spots in the new world to be settled by venturesome Europeans, for nearly a hundred years before our Pilgrim fathers froze to Plymouth rock—in 1533, to be exact—a settlement was made by the Spaniards at La Paz, Lower California.

Further exploration discovered large tracts of barren, arid desert, ruled over by Baal, the sun god, and so the settlements died and it became a haven for unlicensed pirates, who thrived and waxed fat, until

Yet this eastern coast line is rich in varied resources. La Paz is just commencing to find the mineral value lying within her borders; Mulege is beginning to "sit up and note the world do move," and at Santa Rosalia, the Frenchmen are watching with an anxious eye every Yankee who lands there.

As things are at present, El Boleo, the French company which owns Santa Rosalia, is the great drawback to the development of the whole of the east coast north of their property.

They have built here a town of 6000 inhabitants (8000 in the winter), well laid out streets, with concrete sidewalks, sewer and water systems, and lined with comfortable wooden cottages; built a pier, breakwater and smelter, and railroads to all their mines—seventeen in number—and maintain a fleet of ships to France and smaller ones to connect them with the mainland of Mexico. The mines have paid for all these improvements and regular dividends beside.

The absence of any good, natural harbors near

for consolation revealing here and there rich and large mineral deposits

There are big overlays of lava and scoria that can be understood; but half way to the coast are up-thrusts of basalt on top of black obsidian. A pumice stratum is overlaid with sandstone, and this again by jasper.

A big hill of disintegrated granite is superimposed on an immense base of quartzite.

A vein of high-grade galena cuts boldly into a jasper vein, and just across the gulch it reappears in nodules and stringers in a bank of solid gypsum.

There are big blanket deposits of quartzite rich in iron and copper and disintegrated surface material carry 80 cents per ton in gold.

There are quartz, jasper and onyx ledges, dikes of porphyry and blowouts of basalt.

There are hills of calcite, gypsum, breccia, granite and alum

There are veins of magnetite running over 60% iron and immense copper blankets assaying an aver-

Camp at a Spring in the Santa Marias, Baja California.

The Giant Cactus and Mountain Sheep, Typical of Baja California.

La Reforma Peak in the Santa Maria, Baja California.

Santa Maria Mountains Seen Through a Gorge in Lava Fields, Baja California.

King Philip II of Spain sent an expedition about the middle of the seventeenth century, drove out the pirates and established another settlement.

Settlement after settlement was attempted and not until about 1890 was permanency established.

Innumerable colonization schemes have also fallen through, yet the climate is salubrious and the temperature very equable.

Roughly speaking, the peninsula is about 600 miles long with an average width of 60 miles.

Its general trend is northwest and southeast, extending from 32° 40' N. L. to 23° or below the Tropic of Cancer line.

Throughout its entire length a range of mountains, rising boldly from the eastern or gulf side, slopes gradually away toward the Pacific.

Many fertile valleys lie in the interior and each one has its quota of Mexican inhabitants, burros and dogs, yet none of these valleys have their possibilities more than partially developed.

Along the gulf shore the development is still less, for San Jose del Cabo, La Paz, Mulege and Santa Rosalia are the chief settlements in all that long stretch of about 1000 miles of seaboard.

there gives El Boleo a practical monopoly and absolute domination over all the adjacent territory, and they surely exercise their power, for they own the only port of entry and egress, and their "word is law" at the custom house.

Ostensibly the Boleo group are copper ores, but some of them also run well in gold and silver values, but it is all reduced and shipped as copper matte to France, where it is refined, thereby avoiding the heavier duty on gold and silver.

Now, the big mineral deposits of El Boleo do not stop at the Boleo line a few miles north of Santa Rosalia, but the outcrops can be traced 20 miles away, and some day another Boleo will be worked there.

The Santa Maria mountains are about 15 miles north of Santa Rosalia, and contain great mineral deposits as yet undeveloped. Rising boldly from the gulf the highest peaks attain an elevation of 4400 feet, less than 5 miles from the coast.

It is a nightmare of a country to travel over, unless with a flying machine, for that 5 miles is set on edge, seamed with deep arroyos and frightful precipices, bearing everywhere evidence of volcanic action, but

age of 7%. A galena vein outcrops in places for about 2 miles, and a quartz lode carrying low gold values on the surface can be traced fully 3 miles.

Some of the outcrops lie directly at the base of the highest peaks and apparently extend away in under them.

Probably a tunnel into the mountain would tap plenty of water, and water is a desideratum, for the nearest springs are 5 miles away, over an extremely rough and painful trail.

On the northwest and southwest sides of Santa Maria proper, fully 2500 feet above sea level, grow many Taco palms, and, as palms require water and much of it, the inference is that their roots are in moist soil, for they flourish and bear their fruit each season.

The present trail to the coast is about 8 miles, which could be shortened to 6 miles by a rope tramway, and power enough developed thereby to run a dynamo. Such problems would have to be worked out by the superintendent, however—that's what he's there for.

Half way to the coast is a small warm spring,

slightly sulphurous, but quite soft, and excellent for culinary, drinking and washing.

During the rainy season almost every arroyo has its spring; but most of them are so impregnated with alum and gypsum as to be unfit for washing, let alone drinking.

If the smelter be established at the coast, water can be had in many of the arroyos by digging, or a distillation plant could be installed.

Good hard mesquite and palabanco, both excellent firewoods, are abundant and can be bought, delivered at smelter, for about \$4 Mexican (\$2 in gold) per cord.

The other woods indigenous to that section are tovote, dipurer, copal, copal quien, wild fig, date palm, Taco palm and unas gatos (cat's claws).

A breakwater would have to be constructed, for when a gale does come from the northeast, woe to the vessel that is forced against Santa Maria's rocky sides.

The shore is quite abrupt under the gulf waters, and in most places, 200 feet away from the water's edge, the biggest steamers could float with plenty of water under their keels.

There is abundance of hard lava or trap rock on the shore to build piers and breakwater, and the slag from the smelters could be utilized to bond them together.

Another item of some moment is the fact that for about \$15 per month and his beans and flour a Mexican will keep a big camp supplied with fresh and dried fish and turtle.

Probably no other waters in the world are so prolific of fish and sea turtle as the Gulf of California. Last year turtles were selling there for dos reales (25 cents Mexican) each, or about 10 cents gold.

In the Santa Marias themselves are many mountain sheep and deer, rabbits, quail, foxes and chaparral cocks (road runners).

Mexican laborers are plentiful for from 50 cents to \$1.50 (gold) per day, and any company going in prepared to do business will shortly find a large number of natives clamoring for work with them very soon after starting.

It is not a poor man's proposition, for the ores are sulphides and smelting, and the seekers, therefore, must go prepared to run a vessel for supplies to Guaymas and be wholly independent of Santa Rosalia.

There is an abundance of fine fire clay and several veins of kaolin scattered all the way from the heads of the arroyos at the base of Santa Maria to the coast.

In the whole district herein described there is only one mine claimed at present, and it has not been producing since 1893, having lain idle for want of capital and proper management.

The reported assays of this mine, made on the galena vein, are \$6.50 in gold, \$202 in silver (lead not given), by E. Martinez, Mexican Inspector of Mines.

Rightly handled, there is much money for somebody in this locality; but the Mexican proverb, "Una mina quiere otro," ("A mine needs another,") to make it pay, was never truer than in this instance; yet somebody some day will take hold of Baja California, and, in developing its wealth and resources, add to his own and the world's stores.

May it soon be, and the peninsula no longer rank as an undeveloped country!

The accompanying illustrations give a good idea of the character and ruggedness of the country, its vegetation and inhabitants.

### Losses in Treatment of Telluride Ores.\*

Written by A. MONTGOMERY.

It has been the custom of some of the large mines at Kalgoorlie to ship their richest telluride ore either to the Fremantle Smelting Works for treatment or to smelters outside the State, while others contend that a better financial result is secured by roasting the ore locally and treating it by amalgamation and cyaniding after roasting. The advocates of smelting hold that the higher extraction of the precious metals more than makes up for the greater cost of treatment, while the mill men claim that they can extract so much of the metal contents of the ore at a low cost that they can afford to lose the values contained in the tailings and yet show a better financial result in the shape of net profit than if they had sent the ore to the smelters. As the supply of this rich ore to the smelters is at present their mainstay—the quantity coming forward from other sources being small—it was evident that their whole existence depended on their being able to compete successfully with the local mill treatment, and my inquiries were, therefore, directed to ascertaining what were the respective costs and profits resulting from treatment of the ore by the rival methods. Let it be once established that the local treatment gives the better financial result, and the supply of ore to the smelters must inevitably cease. To my surprise and disappointment, I was unable to get from any one of several managers, to whom I went for information, really conclusive figures showing a complete comparison between the two methods on an ore of equal value;

no one seemed ever to have divided a large parcel and treated one half of it by the one process and the other half by the other, to obtain an absolute comparison. The advocates of local roasting and cyaniding treatment appeared to have relied all along on comparative figures showing the costs of the one process as against the other, which would be quite correct if all the costs were taken into account. But when I came to make inquiries I could not find that any one had determined the very important point as to whether there was any appreciable loss of gold by volatilization in the roasting process, which is liable to be quite heavy under certain conditions when salt is present in the roasting charge, as it is in the Kalgoorlie material.

As all the ore raised from the Boulder mines is moistened with the extremely salt water found in them, it is evident that the presence of salt is usual even when the ore is crushed dry and submitted to furnace treatment.

So far as I could learn, very little attention has been paid at Kalgoorlie to possible and probable loss of gold in roasting, it having been generally assumed that the volatilization losses, if any, were so slight as to be negligible. In many cases I found that no systematic assays of the ore were made before it went into the roasting furnaces, and that the extractions reported were based on the assays of the roasted ore, and I did not meet with any person on the field who was able to tell me positively from actual trials whether the loss by volatilization was great or small. It could be easily ascertained by systematically assaying the pulverized ore before roasting, the most perfect sampling being obtainable from this finely ground product, and again assaying the roasted material, making due allowance for the difference in weight due to the roasting. I regard it as a severe reproach to the Kalgoorlie metallurgists that any doubt should be possible on an important point such as this, and have deliberately drawn attention to it in this report in order that steps may be at once taken to have the question thoroughly gone into and conclusively set at rest. While I admit freely that laboratory tests on a small scale are not conclusive in such a matter, it is nevertheless clear that if they show a loss there is a strong presumption that a similar result will be got on the working scale, and demonstration to the contrary is imperative before the presumed loss can be neglected. That there is a loss in roasting Kalgoorlie telluride ores on a small scale is proved by the following experiments supplied to me by J. W. Sutherland:

#### GOLD PRESENT BY ASSAY.

	Raw Ore, Ozs. per Ton of Raw Ore.	Roasted Ore, Ozs. per Ton of Raw Ore.	Loss, Ozs.	Loss, Per Ct.
Fine concentrates.....	5.15	5.00	0.15	2.91
Coarse concentrates.....	4.15	4.00	0.15	3.61
Sulphide ore.....	4.25	4.15	0.10	2.35
Average.....	4.52	4.38	0.13	2.95

A loss of 2.95% is equal to 2s 7.357d per fine ounce, taking the net value per fine ounce at £4 4s 7d, which is about what Kalgoorlie gold comes out at, after deducting mintage, escort, freight and insurance charges, from the field to the Perth mint. On ore of eight-ounce grade, such as is often shipped to the smelters, this loss would amount to £10s 11d per ton of ore. If the actual working process produces a similar loss by volatilization, the amount of gold escaping through the roasting furnace stacks at Boulder must be worth a very large sum of money annually.

Returning to the relative costs of smelting and milling, G. M. Roberts, of the Great Boulder mine, let me have the following figures of the cost of shipping ore to smelters at Fremantle and Dapto, on the basis of stone containing 8 ounces of gold to the ton:

	Fremantle, £ s. d.	Dapto, £ s. d.
Bagging.....	0 15 0	0 15 0
Cartage to station.....	0 1 3	0 1 3
Railage.....	0 16 4	1 6 0
Wharfage.....	0 2 9	0 2 9
Fremantle agency and charges.....	0 10 0	0 10 0
Marine freight.....	0 1 9	0 1 9
Marine insurance.....	0 1 0	0 1 0
Dapto charges.....	2 15 0	2 7 0
Smelting charges.....	0 1 0	0 1 0
Sydney wharfage and agency.....	0 1 0	0 1 0
Percentage of assay value retained by smelters.....	1 5 7	1 5 7
Totals.....	4 18 2	5 7 3
Loss of gold values, fine gold paid for at £14n ounce only, 8 ounces at 4s 7d.....	1 16 8	1 16 8
Grand totals.....	6 14 10	7 3 11

We may summarize the above charges thus:

	£ s. d.	£ s. d.
Transport charges.....	0 17 7	3 0 3
Smelting charges.....	5 17 3	4 3 8
Totals.....	6 14 10	7 3 11

These being the deductions to be made from the absolute assay value of the ore, that is, for 8-ounce stuff, from £33 16s 8d, taking net Kalgoorlie value of fine gold.

The treatment costs per ton at the Great Boulder Proprietary mill for the month of June, 1903, are given by Mr. Roberts, for comparison, as follows:

#### SULPHIDE MILL.

	s. d.	s. d.
Crushing and delivery of material.....	4 7.28	
Roasting.....	3 9.83	
Amalgamating.....	1 6.88	
Supervision (including salaries).....	0 3.81	
Assaying, electric light, clerical, etc.....	0 4.51	
Totals.....	10 8.31	

#### CYANIDE MILL.

Mixing, agitator, and filter pressing.....	4 6.56
Disposal of residues.....	0 11.41
Precipitating.....	0 2.92
Supervision (including salaries).....	0 2.23
Assaying, electric light, clerical, etc.....	1 4.01
Total.....	16 11.44

To compare these with the smelting costs, we have next to consider the values left in the residues, and this presents some difficulty, for the high-grade ores that are sent to the smelters are not sorted out and treated by themselves in the mills, but are mixed with the general produce of the mines. When ores much above the ordinary average of richness are being treated, I understand that it is the general experience that the tailings values also increase, and it is argued from this by the advocates of smelting that if the ores of high grade were sorted out and specially milled by themselves, the tailings would be of high value also. I think this conclusion is a just one, and that the tailings from such high-grade ore would require at least a second treatment, and, possibly, a third, before they could be safely run to waste. It is reasonable to suppose that this is the case also even when the richer ores are mixed with so much poorer material that the average grade is reduced to that of the ordinary run of the mine, and the tailings from a single treatment are no richer than usual. A numerical example will make this clearer. A mine produces, say, 4000 tons a month of ore worth £3 a ton, and 200 tons of picked ore worth £33 a ton. The average value of the 4200 tons would then be £4 8s 7d a ton. If the poor ore were treated separately the residues would probably average about 6s a ton, but if the whole lot was treated together, 8s a ton in the residues would not cause any alarm—but what would it mean?

Total value in tailings.....4,200 tons @ 8s = £1,680  
Total value in tailings.....4,000 tons @ 6s = £1,200  
Difference due to richer ore.....200 tons = £480

Or at the rate of £2 8s a ton. It would obviously be far better practice to treat the rich ore separately by itself, with repeated re-treatments of the tailings, than to mix the lot together. This principle is so well understood in the dressing of tin, copper and lead ores that it is difficult to understand why it should be ignored in the case of gold ores.

The loss in the residues after amalgamation and cyanide treatment at the Boulder mines varies a good deal in different mills and from day to day, and the advocates of smelting express scepticism as to the totals being always correctly confessed; but taking the figures as advanced by the various offices we shall not be above the average result of the practice on the fields if we call the loss 6s a ton on the ordinary milling grades of ore. On the richer grades, however, similar to the ore sent to the smelters, the result would be impossible without at least one re-treatment of the tailings, which would cost probably 8s a ton. Supposing there to be a loss by volatilization to the extent shown by Mr. Sutherland's experiments above quoted of £1 0s 11d a ton, the total cost of milling the rich ore would be:

	£ s. d.
First treatment as per Mr. Roberts' figures.....	0 16 11.44
Re-treatment of tailings (say).....	0 8 0
Values left in tailings.....	0 6 0
Roasting loss.....	1 0 11
Total.....	2 11 10.44

As compared with £6 14s 10d a ton, costs for smelting at Fremantle.

On these figures it would seem that there is no hope for smelting even the richer ores in competition with local roasting and milling treatment, and it would appear that to send them to Fremantle Smelting Works is an absolute throwing away of over £4 10s a ton. The items roasting loss, values left in tailings, and cost of re-treatment of tailings, are, however, all more or less doubtful, and until a careful actual trial has been made by roasting, milling and cyaniding on a thoroughly sampled large parcel of ore of the same high grade as is sent to the smelters, there will always be doubt as to the relative advantages of the two methods. It was a complete surprise to me to find that at this stage in the history of the field there could still exist any doubt on such an important matter. The inferences to be drawn from the figures are unpalatable whichever side is right, for if the milling advocates are correct, an enormous sum has been wasted in unnecessary smelting; and if the smelters are correct, the loss by volatilization, and in the residues, and the cost of treatment, must be vastly greater than are admitted. It rests with each of the managers employing the rival methods to demonstrate by incontestable facts and figures that the method he has adopted is the best one for the ore with which he has to deal.

To DETERMINE the total sulphur in iron, take two grams of the sample of iron, mixed with one gram of pure iron dust, place in a porcelain crucible and cover with a layer of one gram of iron dust. The whole is covered with a disc of filter paper, the crucible lid is put in place, and the contents roasted strongly for ten minutes by means of a blow pipe flame. When nearly cool the mass is decomposed by hydrochloric acid, and the evolved gases passed through a standard solution of cadmium chloride, which is subsequently titrated with standard iodine solution. The results obtained by this method (which occupies less than half an hour) agree closely with those obtained by slower methods.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

EXCAVATING AND DREDGING MACHINE.—No. 785,302; W. Fullard, Plainfield, N. J.

In device of character described, frame or carriage, boring tool, endless belt or conveyor, means for raising or lowering frame and means for raising or lowering boring tool and conveyor independently of frame.

ROASTING FURNACE.—No. 785,437; C. H. Repath and F. E. Marcy, New York, N. Y.

In furnace having plurality of superposed hearths, means for conducting material from one hearth to next hearth below in such manner that there is always uninterrupted body of material connecting material on one hearth with that on next adjacent hearth.

ORE CONCENTRATOR.—No. 785,531; C. G. Weller, Idaho Springs, Colo.

Ore concentrator, combination of box for receiving pulp, slime or material to be separated, perforated pipe journaled in box, arms projected from pipe and forming open work and supports, rotary separating screen mounted upon end supports, they being provided with grooved rims and hubs, fabric of screen extending over grooved rims and hubs, annular binders for clamping fabric to rims and to hubs, and means for feeding pulp to box externally of screen.

MINING DREDGE.—No. 785,263; A. G. Macdonell, Chevy Chase, Md.

Dredge, comprising spaced floats and transverse bridge carrying rigid ladder excavator, bridge being longitudinally movable in space between floats and excavator being vertically movable on bridge, and means for moving ladder forward and thereby forcing excavator against material to be dredged.

PROCESS OF SEPARATING AND REFINING COMPLEX ORES.—No. 785,167; E. Hedburg, Joplin, Mo.

Process of treating ores, consisting in, first, drying ores; second, roasting same; third, subjecting material while heated to action of hydrocarbon gas generated by heat from roasted ore; fourth, partially cooling material, and, fifth, separating magnetic components by passing ore through magnetic fields of progressively increased strength, whereby strongly magnetic ores are attracted by lesser energized magnetic field, and slightly magnetic ores by highly energized magnetic field.

DRILLING MACHINE.—No. 785,352; R. M. Downie, Beaverfalls, Pa.

In drilling machine, combination with supporting frame, of mast or derrick located at one end of same, drive wheel supported on frame in rear of mast or

derrick, spudding mechanism mounted on frame between drive wheel and mast and including crank located in substantially same plane as drive wheel, pitman for connecting crank of spudding mechanism and drive wheel, walking beam supported on frame over spudding mechanism and having rear end above drive wheel, and another pitman for connecting drive wheel and walking beam.

AMALGAMATOR.—No. 785,565; P. McEntee, Spokane, Wash.

Amalgamator comprising sluice having amalgamating plates, means for feeding material to be treated, together with water and mercury, to sluice, collector into which sluice discharges, collector having means for separating water and tailings from amalgam, and free mercury from latter, and means to return recovered mercury to sluice for reuse therein.

ORE AGITATOR AND FILTER.—No. 785,522; V. A. Robinson, Florence, Colo.

Ore agitator involving receptacle having inverted cone-shaped bottom, inverted cone-shaped foraminous supplemental bottom arranged in receptacle, inverted cone-shaped perforated agitator arranged in receptacle in operative relation with respect to supplemental bottom, pipe extending and opening in receptacle above supplemental bottom, and receptacle further provided with outlet below supplemental bottom.

SULPHIDE ORE SMELTING BRICK AND PROCESS OF MAKING SAME.—No. 784,850; J. Furukawa, Tokio, Japan.

Improvement in art of smelting which consists in forming core of charging material, and casting shell of matte all around same.

PROCESS OF MAKING NITROGEN COMPOUNDS.—No. 785,161; A. Frank, Charlottenburg, and N. Caro, Berlin, Germany.

Process of producing cyanides from carbides by heating from dark red to bright yellow heat, carbide that will not melt at these temperatures, reacting upon heated carbide with nitrogen, then melting product of reaction and extracting cyanide in usual manner.

## MINING SUMMARY.

Specialty Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

### ALASKA.

The Alaska-Persoverance M. Co. has put in now machine drills at their mines at Silver Bow Basin.—Assistant Superintendent H. P. Stowe of the Alaska-Treadwell Co. expects to start work on the Alaska-Juneau sixty days in advance of the corresponding date of last year.—J. H. Conrad has brought in machinery to work the Potty silver properties on Windy Arm.—J. Singer of Sunrise, on Six-mile creek, Kenai peninsula, has ten claims on the forks of Six-mile canyon and on East Fork and expects to have the new plant in operation in July.—In the Cook's Inlet district is the \$150,000 dredging plant of the Turnagain M. Co., under the management of A. C. Carter, the plant operated by Girtwood of New York on Crow creek, and the Wichel hydraulic elevators on Canyon creek.

Frank Hammond has resumed charge of work at the mine and mill at Sheep Creek, on the mainland, 4 miles southeast of Juneau.—The Pacific Coast Gypsum Co. will develop their property on Chicago island under the direction of T. N. George of Juneau.

A pay streak has been struck on Edmonton creek, on Discovery claim, in the Stewart River district. It is 35 feet to bedrock and eight pans yielded \$1.40. Bilivieu & Guerin are the owners. The discoverers of Lead creek are prospecting the entire 1500 feet of Discovery claim. The ground proves equally good the full length. The Highest and Duncan claims are proving rich, and, when machinery is installed on Duncan creek, it may prove to be one of the richest in the Klondike.

### ARIZONA.

#### Gila County.

Superintendent W. S. Sultan of the Arizona Commercial Copper Co. of Globe has bought a new hoist for the Copper Hill mine, and cars, track and drill steel. The company has 10 claims north of the Old Dominion mine. The Copper Hill has a 600-foot shaft showing oxide and carbonate ores near surface with an 8-foot vein at the bottom of the shaft.—The Kellner gold mill in Lost Gulch has been closed on account of the continued wet weather, which has filled the several shafts on the Kellner mining property with water and caused the tunnels to cave. As soon as the weather clears the damage will be repaired and the mill will be started again.—Chas. Beck, R. H. Hammer and J. Bice have taken a bond and lease from O. S. Cross on two claims at the head of Pinto creek, adjoining the old Pasquale Negro claim, near Globe. They have started sinking a 100-foot shaft.

Development work has been resumed on the Arizona-Colorado Copper Belt & Gold M. & M. Co.'s mine, near Globe. Two shifts are working under Superintendent J. W. Banbauer, and the force is to be increased to three shifts. A crosscut is being driven from the bottom of the working shaft, 212 feet deep, to intersect the main vein believed to lie 30 to 40 feet to the north.—The Woodson tunnel of the Inspiration M. Co. has been driven 600 feet. J. D. Copper of Globe is manager.

#### Graham County.

(Special Correspondence).—The New England and Clifton Con., at Clifton, will ship from their ore reserves in the mine and also from the large dumps on the Copper King lode. The company has done most of its development work. E. R. Morse, 43 State St., Boston, Mass., is president and A. P. Ayling general manager. Clifton, March 27.

Frank Weist of Globe has taken charge of work at the Starlight mine of the Tri-Bullion S. & D. Co. in the Stanley Butte district, 8 miles south of San Carlos. The company will substitute steam power for a gasoline engine now in use. A station is being cut at 1400 feet in the main tunnel, where an upraise and drifts will be started in ore. The tunnel, which has been run 1600 feet, will be continued 150 feet farther to strike the contact.

#### Mohave County.

It is reported that the Arcadia M. Co. will resume work on its property south of Kingman on the Sandy. P. H. Smith of Windsor, Nova Scotia, president of the company, has been at the property.—The Standard G. M. Co. have started work in the Chemehuevis district, near Kingman, under the superintendence of G. W. Jonas.—It is stated that the new owners of the Elkhart mine at Chloride will put men to work.

#### Pinal County.

(Special Correspondence).—Three carloads of machinery for the new 150-ton smelting plant to be installed near Dudleyville by the Saddle Mountain M. Co., to treat the copper ores from the San Carlos group, have arrived at Florence and will be forwarded to Winkelman as soon as the Phoenix & Eastern line can be reopened for traffic to that point. The three new steel bridges to be put in between Florence and Kelvin have reached Prescott and will be forwarded as soon as possible. The company will not waste any time and material on temporary structures.

Florence, March 27.

The molybdenum possibilities in the mines of the Troy-Manhattan M. Co.'s property at Troy is being investigated and developed by C. O. Schabe, who is at the mine to construct the plant ordered.

#### Yavapai County.

R. H. Brumister, acting for the Arizona Gold Lode M. Co., has bought the holdings of the Advantage G. M. Co. in Groom creek. The 10-stamp mill will be moved to the Arizona G. M. property in Cherry creek and erected there. The Arizona Gold Lode Co. now has a large force at work in Cherry creek and has had excellent results thus far.

Superintendent G. D. E. Mortimer, of the Rincon Mines Co., operating mines  $4\frac{1}{2}$  miles east of Congress,

reports that the shaft is down 950 feet and levels have been run, but no stopping. A mill, cyanide plant and a new hoist have been put in.—The large ore bins and loading device for the Treadwell smelter at Mayor have been finished and are ready for business. These bins have a capacity of 2500 tons.

### CALIFORNIA.

#### Amador County.

J. Isola has charge of prospecting at the Bay State mine, north of Plymouth. At the Rhetta ore is being stoped by six men and treated in the 10-stamp mill of the Bay State.—On Indian creek, 1 mile north of Plymouth, F. A. Orr has been sinking in the Lane shaft. The pump is being run by an overshot wheel. The vein has very little water in it, a concrete bulkhead and clay in the bedrock keeping out the surface water from the creek.

F. Euhanks has charge of men sinking a shaft and running a tunnel on the Jose Gulch mine, southeast of Jackson. J. B. Harris is superintendent.

#### Del Norte County.

T. W. M. Draper, manager of the Monumental mine, south of Waldo, Or., will put on more men to complete the mill and other improvements. Tests will be made on the sulphide ore preparatory to putting in a plant to treat it. Machinery is hauled from Crescent City.

#### El Dorado County.

(Special Correspondence).—The Scherrer ledge at Georgetown may be worked this season.—At the Delwich drift gravel mine, 4 miles northeast of Georgetown, the Union M. & E. Co. have twenty men drifting and breasting cement gravel, which they are reducing in a Krogh mill.—The Georgia Slide diggings are being worked steadily and have produced more than the average amount of gold for the season's work. The value is found in numerous seam veins originally covered with rich placers which were worked fifty years ago. The small seams of decomposed auriferous quartz have been worked chiefly by ground sluicing and hydraulicking.

—A Georgetown company, composed of W. S. Hickman, Guy Wentworth, A. Orilli and A. Presby have brought down a 2-stamp mill from the Little Gem mine, near Josephine, and have put it on the Hanson claim directly on the line of strike south of the Georgia Slide claims, where the seams are more numerous and massive. They propose milling across the formation which here is nearly 150 feet wide, and is said to prospect well. Mining operations for many thousand tons will be of the open quarry style above the level of the car track to the mill.—McDougal, Chisholm & Co. of Georgetown have a lease on the Cranes Gulch claim and are preparing to sink deeper on the seam in the contact of the Mariposa States and Amphibolite, which has in past workings produced some good ore.—Superintendent W. E. Everson has put in two 60 H. P. boilers and a sinking pump at the Woodside-Eureka at Georgetown, and has prepared the hoisting plant for rapid work. The boilers and pipes have been covered with asbestos worked up from the company's mines near Georgetown. Georgetown, March 28.

C. Schulze of Coloma says that the Schulze & Patrick mine on Mt. Murphy is doing well and that they will put a small mill on the property.—The new hoist of the Larkin mine, near Diamond Springs, has been completed, and the shaft is being retimbered preparatory to sinking 200 feet deeper.

At the Last Chance mine, near Nashville, Superintendent J. O'Brien, of Plymouth, is opening up a good ledge. It is reported that a mill may be built on the property.

#### Mono County.

C. A. Fohrman of Bishop, general manager of the Casa Diablo, 22 miles north of Bishop, will build a 20-ton stamp mill and a 50-ton cyanide plant this year.

#### Placer County.

Work has been resumed at the Full Moon mine, near Michigan Bluff, by Superintendent G. Smith.—L. C. Trent has charge of the Dairy Farm mine, near Lincoln, an interest in which is reported sold to Du Pont-Nemours Powder Co. of New Jersey. This is a copper property at which attempts have been made to cyanide the gossan.—The Aelia M. Co., at Blue Canyon, is running a 400-foot tunnel and will upraise to strike the main channel.—Gravel has been struck at the Strawberry mine, at Monona Flat, near Iowa Hill. J. Watts, Sr., is the principal owner.

#### Shasta County.

Work is to be resumed on the Pawnee group on Wildcat creek, 3 miles from Bear Valley station, by J. T. Weeks of De Lamar (Winthrop P. O.).

The 175-ton smelter built by the Groat Western Gold Co. at Ingot, the new smelter town on North Cow creek,  $1\frac{1}{2}$  mile below the company's Afterthought mine, has been blown in.

#### Trinity County.

The 10-stamp mill at the Brown Bear mine, at Deadwood, has been started and is crushing ore supplied by the leasers. F. P. Satterlee has charge.—J. Betham, general manager of the Lappin mine at Deadwood, reports work progressing as fast as can be expected on the lower tunnel, which will tap the ledge at a much greater depth than the present tunnel and shaft. The opening of this level will enable them to keep the mill running steadily on good ore. The management expects to have an air compressor put in and then machine drills will be used. It is expected that the tunnel will be completed by July 1st.

#### Tuolumne County.

At the Horse Shoe Bend mine, near Columbia, a night shift has been put on in the 90-foot shaft, where the vein is increasing in value. Assays run from \$8 to \$80. In the Englewood tunnel four drills are being operated and the vein keeps up in size and quality. Another compressor is soon to be put in.—The recent strike in the Denmore mine, on the Stanislaus, near Columbia, owned by a Sonora company, is said to be as extensive and rich as any ever made by the former operators.—The Little Bonanza pocket mine, near Sonora, yielded a few thousand dollars recently. Indications for another strike are said to be encouraging.—The Brindle Pup

mine, between Vine Spring and the Doyle Ranch, has been equipped with a 4-foot Huntington mill.—The four claims, known as the Last Chance, Free Gold, Chas. Haley and Wilbur, contiguous properties a few miles east of Jacksonville, have been handed to E. L. Flower and J. B. Watson, who say they will develop the claims.—Several tons of ore were put through the Hope mill this week at Sonora.—Preparations are being made to resume operations at the Basin mine, north of the town of Tuolumne, which for a long time was involved in litigation. The mine is east of the North Fork of Tuolumne river.—J. Gibbs and W. Symons of Sonora have a bond on a claim recently located by G. F. Copeland, situated 8 miles from Tuolumne, on the North Fork of the Tuolumne river. There are three parallel veins on the claim, which have been traced the full length of the claim and are of good size, and carry free gold in paying quantities on the surface.—Articles of incorporation of the Eagle Bluff G. M. Co. have been filed with the Secretary of State: President and general manager, F. M. Meigs; vice-president, D. M. Garner; secretary and treasurer, A. Hughes; directors, G. S. Berry and E. W. McCutcheon. Meigs and Garner will look after the work at the mine, near Groveland, and it is reported will put a mill on the mine.—F. F. Werner of Oakland, Cal., and G. C. Rawson, C. Sonningsen and C. Crimin of San Francisco, Cal., have gone to the Jawhouse country, southeast of Groveland, with all the tools necessary for a prospecting camp, and provisions for three months. Mr. Werner has a hoist on the claim there. He intends to resume active operations when the weather permits. The others will open up new ground in the vicinity.

### COLORADO.

(Special Correspondence).—A plan has been placed on foot by the directors of the American Mining Congress, which held a meeting in this city a few days ago, to erect a handsome and commodious building at this point, where the offices of the Association will be permanently located, together with a large mineral display. A number of prominent mining men and operators, who have not allied themselves with the Association heretofore, are in favor of the project. At the meeting recently held here a number of questions pertaining to the needs of the Congress and the industry it represents were discussed. The next national convention will be held in El Paso, Texas, Nov. 14, 1905.

On the strength of the passage of the eight-hour law, the Western Federation of Miners have declared the strike which was started two years ago at the smelters at an end. They claim to have won a victory on account of the passage of the eight-hour law. It is believed a test case will be made and taken to the Supreme Court for an opinion as to whether the law is constitutional or not.

The bill appropriating \$125,000 to establish an independent oil refinery in the State does not seem to meet with ready adoption by the Legislature. The independent operators of the State are very aggressive in trying to get the measure adopted, as it means much to them.

The suit now on trial in the District Court of J. B. Hindry against the smelter trust for damages to his property promises to be long drawn out. The smelter people have introduced testimony to prove that the failure of crops on the Hindry ranch is due to lack of water for irrigation purposes, rather than on account of smoke and poisonous fumes from the smelter. The testimony would indicate that other ranchmen in the vicinity of the smelter do not find any trouble in raising good crops. The past few years Hindry, according to witnesses, has failed to irrigate his place as it should be to insure a good production.

Prospectors are turning their attention to the Junkins Park district, in Custer county, and it is to be hoped that the new discovery will prove to be a permanent thing.

Denver, March 27.

The eight-hour law has been passed by the Colorado Legislature and signed by Governor McDonald. The law as passed is as follows: "All labor of miners in underground mines, or other underground working, and labor directly attending blast furnaces, either in smelters or in ore reduction works, indirectly attending stamp mills, chlorination or cyanide processes and directly attending smelting furnaces producing metal or matte, which labor is in contact with noxious fumes, gases or vapors, is hereby declared dangerous and injurious to health, life and limb; and the period of employment for all persons so employed in underground mines or other underground working, attending blast furnaces either in smelters or ore reduction works, in stamp mills, in chlorination and cyanide mills, and attending smelting furnaces producing metal or matte, shall be eight hours per day, except in cases of emergency where life or property is in imminent danger. Every person, body, corporation, manager, agent, superintendent, employer, president or director shall, in every case of such emergency, make to the commissioner of the bureau of labor statistics, within ten days after the commencement of such emergency, a report, according to the form which may be prescribed by him, verified by the oath or affirmation of such person, employer, agent, manager, superintendent, president or director; each report shall exhibit in detail the circumstances creating such emergency. Any violation of this Act shall constitute a misdemeanor and he punished by a fine of not less than \$50 nor exceeding \$300."

#### Clear Creek County.

The Anglo-Saxon M. & D. Co. will build a 100-ton concentration and reduction mill and cyanide plant on the Saxon Extension property on Saxon mountain, near Georgetown. The 800-foot tramway from the mine is nearly finished.—On Democrat mountain, near Georgetown, the Red Oak is being worked successfully by leasers, including A. Roberts, A. J. Olsen, J. Jones & Co. and Teagarden & Mauff.—The tunnel of the Silver Leaf on McClelland mountain, near Georgetown, has been driven 270 feet, and Manager B. Mantelore of Idaho Springs has given a contract for 300 feet more.—J. J. White will place machinery at the Headlight shaft of the American Sisters mine, near Georgetown, preparatory to sinking.—Machine drills have been put in the

Capital Prize tunnel being driven into Griffith mountain. — The Woodstock property in the Atlantic mining district will resume in the spring under the management of J. S. Fisher. A shaft has been sunk 60 feet on the vein.

An electric motor of 150 H. P. has been ordered for the Gem shaft at Idaho Springs, which will be used to operate the new Rand cross-compound 10-drill air compressor. All air columns in underground workings of the Gem properties will be enlarged and overhauled during the next few weeks. The work is made necessary on account of the extensive operations planned for the coming year. The company has a steam and a water power electric generating plants, as well as the water power and steam compressor plant at the Silver Age station, from which the compressed air is piped over the mountain nearly 2 miles to the workings. Work has been started in driving the fourteenth level west from the Gem shaft, and the other lower levels will be started as soon as conditions will permit.

The Wilcox tunnel in East Argentine district is tapping large streams of water as well as veins of ore, and work had to be stopped for a time because of the large flow of water encountered. It is thought that the heading of the tunnel is near the Santiago lode where it extends into the Waldorf Co.'s ground, and that a great deal of the water is coming from that lode. The Santiago workings have been drained by the tunnel, which cuts the vein about 700 feet deeper than the present workings on the Santiago holdings, which lie west of the Waldorf holdings. The Wilcox tunnel is in 4000 feet. The Tobin tunnel, above the Wilcox, has cut many ore veins which were large producers from the surface workings and show good streaks of mineral where cut by the tunnel. This tunnel is being driven to connect with the ninth level of the Stevens property on the opposite side of the mountain, which it is expected to reach within a few months. Both of these tunnels are provided with power plants.

#### Fremont County.

The Dorcas M., M. & D. Co., operating in Florence, will enlarge its cyanide plant by adding three barrels and an extra hopper to the present equipment. These will increase the capacity of the plant 25%. Excavation work for the foundation is under way.

#### Gilpin County.

The Rocky Mountain Terror mine in Russell district will be worked by the Russell Gulch M. & D. Co., of which G. K. Kimball, Jr., manager of the Old Town mine, is to be president and manager. The main shaft is down 400 feet and will be cleaned out and arrangements made for the opening up of the property. S. B. Bontems, 452 Kittredge Building, Denver, Colo., is secretary and treasurer. — The Gem mine near Russell is being operated under a lease by Mellow & Co. of Russell Gulch. They have sunk the shaft 250 feet. They have commenced drifting at the bottom on both sides of the shaft and are also stoping at the 200-foot level. Hoisting is being done with a whim, but if deeper operations are found necessary, machinery will be put in. The property is owned by St. Louis, Mo., parties for whom E. W. Davis, Central City, is agent. — At the Prompt Pay mine in Russell district the shaft will be sunk 100 feet from the 175-foot level and a crosscut will be driven to the north to cut another vein on that side of the property. The Prompt Pay M. & M. Co. are working the property. E. O. Williams is in charge. — It is reported that the Delmonico property, on the south side of Quartz hill and at the head of Leavenworth gulch, is to be re-operated under the superintendency of E. Stefan. The shaft is down 1300 feet. The mill will be started.

#### Gunnison County.

Work is going on on the Grand Prize group, near Pitkin, under the supervision of W. Friend. A whim has been placed and good ore is being taken from a 15-inch vein in a drift run from the bottom of a 55-foot shaft. — The incline shaft on the Cortland is down 235 feet, with a vertical depth of 185 feet, in the bottom of which is showing a 10-inch vein of high-grade silver ore. The upper levels, from which the high-grade ore only had been taken, leaving the low grade, are being cleaned out and the dump is being enlarged with a good milling product. — The Chloride management, in the Gold Brick district, near Pitkin, has opened up some good ore in the upper workings. The pump is kept running to unwater the lower levels. — McWilliams & Jett of Pitkin have a contract to sink a 50-foot winze in the Golden Islet and are doing good work. — The Gold Links tunnel is in 1100 feet and being driven with three drill shifts of one drill each.

At the Enterprise mine, at the head of Taylor park, a 4-foot vein of pay mineral has been struck in the breast of the 4000-foot tunnel. The company will put in a mill to treat the ore. — Merriman, Cummings & Beymer will put up a mill to treat the ore from the Abe Lincoln, near Bowerman. The tunnel is in 350 feet.

#### Jefferson County.

(Special Correspondence). — The Independent Smelting Co., operating at Golden, claim to be receiving plenty of ore. It is understood the trust has again reduced their charges in order to put the Independent plant out of business. The rate has only been cut on the ores that the Independent plant is able to handle.

Golden, March 28.

#### Lake County.

Partridge & Jones of Colorado Springs will start work in April on the Lucky Joe shaft on Rock hill, Leadville. — T. J. Cash and C. H. S. Whipple are working the Triumph on Johnny hill, Leadville. — At the Fannie Rawlins, T. Kyle and partners are shipping thirty tons daily from the 400-foot level. — The Highland Mary, on the north slope of Breece hill, which has not been worked for several years, is again in commission and shipping 400 tons a month. The property is under lease to R. Shipley and E. Vernier of Leadville.

#### Ouray County.

Work has been started on the 1000-foot tunnel recently contracted by the Camp Bird people to explore the property acquired from the Imogene Basin Gold Mine Co. Aside from exploring this mineralized territory the tunnel will solve the water problem for the

Camp Bird, and is to be 7½x8 feet with a ditch in the bottom 20x20 inches for the purpose of conveying the water. — The Ouray Con. M. Co.'s tunnel near Ouray has been driven 390 feet and is making 2½ feet per day by hand. A wagon road is being constructed connecting the dump with the county road below. It is possible that power drills will be put in to expedite the tunnel. — Operations have been resumed on the Denver mine in the amphitheatre near Ouray, by the Arps Bros. — A tunnel is being driven between the Barstow and Joker Tunnel by Marion Leek to cut the Barstow vein which is believed to come through this section. The owners of the property are the Imogene Gold M. Co. The tunnel will have to be run a distance 200 feet to cut the point where the vein is supposed to be located. — The development tunnel being run by the leasers of the Black Girl, Faussone et al., is 100 feet.

#### San Miguel County.

G. Moody is working the Jim Say property, 5½ miles up Bear creek from Newmire. He has put pumping machinery in the shaft, which is down 75 feet. — F. Fortier is working in Liverman gulch, a branch of Spruce creek that empties into Bear creek, 5 miles from Newmire. He is down 75 feet in his shaft. — The Carribeau-Montezuma mines at Ophir are employing forty men and more will be added. The concentrating plant is treating forty tons of mineral daily, and shipping several carloads of concentrates each week, four to six tons of crude ore being reduced to one of concentrates. At the Carribeau mine several drifts are being extended, opening new areas of ore, and a tunnel is being driven for the purpose of draining some of the lower stopes of water. When the latter is completed operations will be facilitated, and it is probable the force will be largely increased. When the development in the mine has progressed sufficiently to warrant it, the company intends to enlarge the milling plant and make arrangements for treating 100 tons of mineral daily. — The new tunnel on the Butterfly-Terrible mines at Ophir Loop, 14 miles from Telluride, is in 600 feet, and on completion it is calculated it will be 2500 feet in length. Its purpose is to intersect the extension of the Ida vein ore shoot, from which the mill has been supplied with mineral for the past year from between the first and third levels. The tunnel will cut the shoot 750 feet below the third level, and will furnish the key to an immense body of ore. Two shifts of men with machine drills are driving it. For a while it was run on a vein, but the latter deviating from the course of the tunnel it has since been driven straight ahead through country rock. — The Butterfly 30-stamp mill is treating seventy-five tons daily, twenty of the stamps being run by steam and ten by water power, but it will not be long until the thirty, as well as the air compressor and machine drills, will be operated by water power. — At the annual meeting of the Butterfly-Terrible Gold Mining Co. in Denver, Calvin Bullock of Denver was elected president; F. J. Hobbs of Colorado Springs secretary and treasurer.

The Ouray Herald reports that preparations are being made for excavating for the foundation of the Atlas mill, part of the machinery for which is now being shipped in. It is expected to have the mill running not later than the middle of July. The mill will be capable of handling 100 tons daily, but at first only a 25-ton capacity will be installed to test the adaptation of the mill to the ore to be handled. All the arrangements of the buildings, power, etc., will be for the 100-ton capacity. The ore from the upper workings will be conveyed to the Chattahoochee tunnel by wagons, and will be transferred from there by an aerial tram to the mill, 2500 feet below. The ore body in the upper working has an average width of about 3 feet. A tunnel has been driven on the vein 1000 feet and raises made to block out the ore, of which 100,000 tons is estimated to have been blocked out, the values ranging from \$12 to \$15 to the ton. The depth attained by the upper tunnel is 500 feet. The Chattahoochee tunnel which is now being driven will cut the same vein at a depth of 1000 feet. The new drills recently installed in the last-mentioned tunnel are giving good satisfaction, and it is expected the vein will be cut within the next ten months—a distance of 2000 feet. Men are at work in the upper tunnel to block out the ore bodies and keep the development ahead of the mill.

#### Summit County.

(Special Correspondence). — The Jessie mine and mill in Gold Run gulch are working to full capacity. Several carloads of concentrates have lately been shipped, and the month of February showed a handsome profit to the leasers.

The Washington-Joliet M. & M. Co. are working away on the various parts of their large workings and keeping the 20-stamp mill pounding away, turning out a good grade of lead, gold and silver concentrates, besides the bar gold obtained from amalgamation. The Washington ledge has lately produced shipping lead ore, carrying three ounces of gold per ton. The preliminary arrangements are being made for working their placer ground this spring and summer.

The Lucky M. & M. Co. expect to start the mill next month. The Paducah claim is producing some fine milling ore as well as some of shipping grade.

The 100-ton concentrating mill of the Old Union M. & M. Co. in French gulch is about finished. The eight Wilfey concentrating tables and four slimmers are in position. The machinery starts early next month. The main tunnel is in 560 feet; crosscuts are being run. They are still in ore. The body is over 18 feet in width, with no sign of the containing walls yet at hand.

The Colorado-Wyoming Development Co. is developing, and continues to ship lead and zinc ore. They have a quantity of lower grade ore waiting treatment by milling and concentration.

The big placer companies are now arranging for active work. The North American G. D. Co. will soon be at work with their Bucyrus dredger and their plant on the Peabody placer.

The Reliance G. D. Co. expects its machinery soon. Leasers are working on the Germania mining property, with excellent results to themselves and to the owners. This property produces a high-grade silver-lead ore.

The Gold Dust Lode claim is being worked by leasers

and a good shipment is expected. Leasers are also at work in a portion of the Washington property. Foote & Hight shipped a parcel of eighty tons of zinc-iron ore from Gibson hill which gave good returns.

At Frisco the Excelsior, Mary Verna and North American are active.

Recent strikes of good ore on the Silver King, the Washington-Joliet, Laurium and other properties on Nigger hill will cause a number of good prospects in that vicinity to be worked during the coming season. The Croesus group, upon which a good amount of work has been done, is expected to resume operations shortly.

At the Laurium the main tunnel into the mountain is in 1250 feet. Three veins have been intersected, in two of which good milling ore is opened up, carrying gold and silver in lead and iron sulphides.

Breckenridge, March 25.

(Special Correspondence). — Hoyle & Hoyle, who have been leasing on the Gold Dust, Puzzle and Eighty-six claims for some time past, have organized a company capitalized at \$1,500,000, known as the Gold Dust Mines Co.; E. J. Hoyle, president and treasurer; M. W. Hoyle, secretary and manager; R. R. Kirk is one of the incorporators. The new company will continue to operate the properties above mentioned and have mapped out considerable development work which will be carried on. Some improvements in the way of machinery will be added to the property later on.

Breckenridge, March 27.

The Senator tunnel, near Breckenridge, has been run 800 feet and in the Senator vein.

#### Teller County.

The B. & M. G. M. Co., operating on the Norfolk fraction, adjoining the Jerry Johnson and W. P. H. claims, on Ironclad hill, Cripple Creek, has come into good ore in a 50-foot shaft. J. H. Hobbs, who secured a lease from the Stratton estate on the Orpha May Nos. 1 and 2, is sub-leasing, as is also Lessee Cox, who has the American Eagles. — The Irene Leasing Co. will continue the shaft of the Prince Albert on Beacon hill, Cripple Creek, from the 245 to the 385-foot level, where crosscuts will be run. Hoisting machinery has been put in. — W. P. Dunham has leased the Right-all-Right, the Finn and the Olive Branch, on Ironclad hill, Cripple Creek. — J. K. Walsh, leasing the Forest Queen, on Ironclad hill, is shipping ore. — Billerbeck & Gilbert, lessees, will put in machine drills to facilitate sinking in the Vera Beemer claim of the Banner G. M. Co., on the western slope of Beacon hill, Cripple Creek. The shaft is 86 feet deep and will be continued 50 feet farther before crosscutting. — The Sioux M. & M. Co. will start up the Sioux Falls mill on the Fluorine property, Copper mountain, near Cripple Creek, April 1. R. Blanchard, superintendent, is making an upraise from the tunnel level to the old stope or open cut, from which it is proposed to tram ore to the mill.

After an abandonment of three years, the Orpha May mine at Cripple Creek is to be operated by lessees headed by J. H. Hobbs of Colorado Springs, with David Mason as superintendent. — The Fort Pitt mine on Galena hill, near Cameron, is shipping ore from the bottom of the 500-foot incline shaft. Sinking another 100 feet will be started April 1. — The Monument mine on Battle mountain, Cripple Creek, has been sold to V. Z. Reed and associates for \$90,000. Superintendent H. Pring will sink the shaft from the 450 to the 1000-foot level.

Discovery of a valuable ore body is reported by Lessees Boyd & Herr in block No. 34 of the Anaconda estate, Cripple Creek, which is reached through the adit entering from the south slope of Gold hill. The ore body has a width of 18 inches. — The Granite G. M. Co. has sold to the Portland Co. the Baby Mine claim, which lies on the east side of the Granite claim, adjoining Portland ground. The piece of ground transferred measures 26x86 feet. — The Camilla Co. at Cripple Creek is raising its gallows frame and expects to have its large plant of machinery in place soon, when mining operations will be started. The shaft is 150 feet deep, and this will be sunk another 150 feet, when laterals from this depth will be extended in different directions. — Kenzy and associates, who recently opened up a good vein of ore at a shallow depth in the Bob Lee property on Tenderfoot hill, have the new shaft house completed and a new complete plant of machinery installed. — The greater part of the Modoc property, embracing the Ocean View (10 acres) and the K. P. Extension South (10½ acres), on Bull hill and Battle mountain, Cripple Creek, will be leased by Manager Frankenberg. That part of the property lying between the third level and the surface will be retained and operated by the Modoc Co.

## IDAHO.

#### Idaho County.

(Special Correspondence). — Idaho is experiencing a phenomenal condition for this season of the year, there being but little snow in evidence, where usually it lies deep on the mountains. "Old-timers" state that it is the greatest shortage in twenty years, and, unless we can note a rapid change in conditions, placer mining will suffer on account of lack of water in the ditches and a short season will result.

Newsome, March 26.

The Grangeville mines, near Elk City, have been secured by the Silver Giant M. Co. of Spokane, Wash., and will resume work April 1. They expect to put in a milling plant this season.

F. S. Allison has struck good ore on the Reliance group, 25 miles southeast of Roosevelt, at the head of Reardon creek, near Black Lake.

A 10-stamp mill is running on the Atlas property, Buffalo Hump, the ten stamps having succeeded the five stamps that had been in operation. This property is owned by Howell Peel, George Crane and others of Salt Lake City, Utah.

#### Shoshone County.

It is reported that Chas. Sweeney of Spokane has sold his stock in the Federal M. & S. Co. for \$2,650,000, possibly to the Guggenheim interests.

Galena and zinc ore has been struck in the Surprise group, on Pine creek, near Wardner, by W. Yetter. — A new ore shoot has been found in the Steward M. Co.'s property, on Steward gulch, near Wardner. H. F. Sam-

uels of Wallace is interested.—The Custer mine, on Nine-mile creek, is hand-jiggering ore taken out during the winter and shipping the concentrates. Machine drills are to be substituted for hand work as soon as the ore in No. 2 level has been cleaned up. The company is working ten men. The property is under bond to W. R. Swicegood of Frisco and A. Baker of Joplin, Mo.

Shipping ore has been opened up in the lower tunnel of the Stewart mine at Wardner. H. F. Samuels and associates are the owners.

#### Washington County

The Iron Springs Con. M. Co. at Iron Springs, 5 miles north of Black Lake, has ordered a 200-ton cyanide plant. Owing to the unprecedented light snowfall in the mountains this winter, the roads will be open several weeks earlier than usual, and the machinery can be taken in and the plant be in running order by next fall. D. C. Nevin is manager.

### KANSAS.

The Standard Oil Co. has discontinued giving jobbers and wholesalers in Kansas concessions in price on refined oil and gasoline. The effect of this order will be, it is said, to take the business of the handling of the kerosene away from the wholesalers, who now will have to pay the retail price for these commodities.

### MONTANA.

#### Broadwater County.

At the Park properties of the Mason syndicate, near Hassell, seventy-five men are employed and development is being pushed. The tunnel is in 1200 feet to tap the main vein. There is plenty of ore to run the 100-ton concentrator from the old workings. A postoffice, Mason, has been established, with a daily stage from Townsend.

#### Fergus County.

G. M. Nelson of St. Paul, president of the Chicago-Montana G. M. Co., which closed down its mines and mill at Whisky Gulch, March 1, owing its miners and millmen two months pay, amounting to \$15,000, has been at Gilt Edge to make an examination of the property and ascertain the exact shape in which the company's affairs stand. He hopes to start up the property again.

#### Flathead County.

The Silver Giant M. Co. of Spokane, Wash., has acquired the Big Eight mine, near Troy, and will sink the two-compartment shaft from the 160 to the 300-foot level.

#### Jefferson County.

J. Steinbrenner, developing the Carbonate Chief group in the Warm Springs district, near Clancy, has a large vein of ore from which he is shipping about 300 tons a month to the East Helena smelter.—The White Pine Co. in the same district, near the Carbonate, are taking out good ore and shipping. The property is developed by two 500-foot tunnels.

There is more activity in the mining districts around Clancy, 9 miles from Helena, than for years before, and the season promises to be an unusually busy and prosperous one.

A syndicate of Chicago, Ill., capitalists will develop the property of the Wickes-Corbin Co. at Corbin this season. Mr. Bird, who controls a number of claims in that vicinity, is making explorations with a diamond drill.

#### Lewis and Clarke County.

(Special Correspondence).—Manager F. L. Sizer, of the Whitlatch-Union mines, south of Helena, expects to be able to get into the old workings the latter part of April, as the water in them is receding rapidly owing to the drainage through the new workings, which are now below those made in former years. The new hoist installed at this mine is in successful operation and this will permit much more extensive and deeper development than was possible before. Ore is coming from the 400 level, of which twelve to fifteen cars are shipped monthly to the East Helena smelter. Another vein—the "Mac"—is known to lie below that opened and it is thought that in another 100 feet of depth this vein will be reached. A mill is contemplated, and the hoist, pumps, mill, etc., are all to be operated by electric power. The ore shipped has netted about \$700 per car. The Penobscot property remains idle, though it has much promise. The last attempt to work it was about five or six years ago, when the old workings were searched for pay ore, but little new development accomplished. The property now requires the expenditure of a considerable sum of money in vigorous development, with a view to opening up some new ore bodies. It is situated near the noted Bald Butte mine, which has been one of the best gold producers in Montana.

Helena, March 26.

A vein of copper has been struck in the property of the Brooklyn Bridge Co., 4½ miles south of Helena. The strike was made at a depth of 330 feet, and it is the intention of the company to sink 700 feet in the expectation of opening up larger bodies.

#### Madison County.

The Moonlight mine, owned by Carroll & Martin of Helena and F. L. Sizer, is making shipments, the ore averaging \$140 per ton. The owners of this property propose to do much more work in this vicinity this season than before.

The Red Bird M. Co. of Helena is developing three of their properties—the Red Bird and Copper Hill, near Austin, and the Reliance, in High Ore gulch. The shaft on the Copper Hill will be sunk another 100 feet. Ore is being taken from the old workings of the Red Bird and larger machinery will be put in to develop that property to a greater depth. On the Reliance extensive development work will be done. Shipments from all these properties have been extensive and profitable.

The Inter Ocean Co., developing a group of claims on Red mountain, at Rimini, has its tunnel in 1800 feet and has cut several veins, the last being 30 feet wide with two pay streaks, the ore running in gold, silver and lead.

The Black Hawk mine, owned by the Mason syndicate, is running steadily. New and extensive development is to be undertaken this season.

#### Missoula County.

An air compressor is to be put in at the Montana-Standard mine, 11 miles from Thompson, by J. Murphy. Water will be flumed 1½ mile from Crow creek.

Y. E. Gresslee of Baltimore, Md., secretary and treasurer of the Grangeville Quartz M. Co., is at Clinton arranging for the establishment of a smelter at Clinton. It is the idea of the company to put in a 50-ton-per-day smelter, and if the owners of the adjoining mines will agree to have their ore treated at the company's plant they will put in a 100-ton smelter.

#### Park County.

C. R. Tuttle, secretary and general manager of the New World Smelting Co., has gone to Livingston, Mont., to make arrangements for the installation of a sampler and smelting furnace at New World City which he reports having ordered. He is also making arrangements for ore deliveries.

#### Silver Bow County.

(Special Correspondence).—The Amalgamated Copper Co. produced copper during March at the rate of 650,000 pounds per day. During February the total production at the Washoe smelter exceeded 12,000,000 pounds, but during the first week of March the production averaged 428,572 pounds per day. During the first twenty-five days the Washoe output was 10,714,300 pounds. The smelter treated 7000 tons of Butte ore daily, which went over sixty-one pounds of copper to the ton. The Amalgamated Co. treats 3000 tons daily at the Boston & Montana smelter at Great Falls, and 600 tons a day at the Butte & Boston smelter at Butte. The Boston & Montana ore averages higher in values than the ores treated at the Washoe, but taking the same yield of copper per ton the total daily production of the Amalgamated Co. would reach 648,172 pounds per day, or a total for March of 20,093,332 pounds. At 15 cents the daily value of the Amalgamated output is \$97,225.70. In addition, ore yields gold, silver, arsenic, etc. The average in recent years for gold and silver was 2½ cents for each pound of copper produced, and it has been estimated that the by-products about pay for operating expenses and cost of production. The capacity of the Washoe smelter at Anaconda is being increased, and in three months it has been raised from 5500 tons of ore daily to 7000. The smelter treats daily 7000 tons of ore, 550 tons of coal, 400 tons of coke and 1500 tons of lime rock. A year ago much of the ore that is now being treated at a profit was left in the mines as waste. Since the first of the year eight roasters have been added to the plant, and the last of the old small reverberatory furnaces has been torn down, and six new ones are completed and the seventh is nearly finished. The hearths are 116 feet long, 19 feet wide. Each reverberatory handles 300 tons of ore a day. The new arsenic plant has been in operation for several weeks and will soon make shipments. The material for the arsenic plant comes from the long flue that runs from the smelter to the smokestack ½ mile from the smelter. A portion of the dust from the flue is rich in arsenic and is taken to the refinery which it leaves 99.9% pure.

Butte, March 27.

#### Yellowstone County.

J. B. Salisbury of Grand Forks, N. D., has reopened the Shafter mine and mill at Summit after a winter's inactivity. He will begin work on a deep shaft as soon as the snow is off the ground.

### NEVADA.

#### Humboldt County.

M. D. Smith, superintendent of the Golden Eagle mine at New Central, near Winnemucca, reports that some of the men have been laid off from the mine pending the enlarging of the cyanide plant. This work will take about thirty days, and it will be May 1st before a full force will be put on.—The United States Smelting Co. have shipped 395,000 pounds of fluxing iron ore from the Vulcan mine on Winnemucca mountain since March 15th. All the ore containing anything but iron is being piled on the dump for shipment later. The reason for this is that the Southern Pacific Co. gives a special rate of \$4 per ton on pure iron ore to be used for fluxing. Superintendent Nichols says all he wants is ore that will run high in iron, and all that contains any other metal is put aside for shipment later.

#### Elko County.

W. D. Higginbotham, manager of the White Rock Placer Co. at Elko, expects to resume sluicing in April.

#### Esmeralda County.

(Special Correspondence).—The Royal G. M. Co. of New York, J. D. Hoff, M. E., manager, has leased 300 by 300 feet of the Combination M. Co. of Goldfield and work started. They also own 120 acres of ground northwest from the Sandstorm, on which development work will be started.

Goldfield, March 27.

C. L. Marsh plans to ship freight from Salt Lake City, Utah, by way of the Clark road to Caliente and from there by team to Goldfield, giving the following freight rates between Salt Lake City and Goldfield: First-class freight, \$3.73; second-class freight, \$3.56; third-class freight, \$3.41; fourth-class freight, \$3.25 for each 100 pounds, and a proportionate rate to all other points in southwestern Nevada, time not to exceed twelve days from Salt Lake City to Goldfield.

L. Bleakmore, J. S. Cook and W. H. Lang of Goldfield have bought the Shoshone property of R. Montgomery at Bullfrog for \$800,000.

#### Lander County.

At Battle Mountain the Humboldt mines are being worked under a bond by L. A. Jeffs.

#### Lincoln County.

F. P. Swindler, general superintendent of the Bamberger mines and mill at De Lamar, is waiting the approval of Simon Bamberger, after which he will proceed at once with the construction of an auxiliary plant which will enable him to reduce 700 tons of gold-bearing tailings from the old mill daily, the plant as designed providing for eighteen steel leaching tanks, with twelve for the slimes.

J. Bullen and N. Dunne have sold the Mikado group,

south of the Virgin river, to McMasters, Flick & Bloom of New York City for \$7500. The new owners will put six men at work immediately taking out ore.—Lassen & Wilde of Baltimore, Md., have taken an option on the Santa Anna gold-copper claims, north of Good Springs, from Ray & McWilliams of San Diego, Cal., for \$12,000. There are twelve claims in the group on which over 500 feet of work has been done.—Norton, Gohson & McBride have taken an option on the Lost Cabin group of eight claims, 42 miles west of De Lamar, from Gillen, McWade & Leeson, for \$5000, and will put men at work.

Hansen & Wilson, leasers on the Hidden Treasure gold mines, on the upper Virgin river, report a clean-up of \$4500 for the past three months. This work was done on the old river bed, which was struck four months ago.—Gordon, Fletcher & McBride, owners of the Prospector group of gold-copper claims northwest from Moapa, have completed their ore road and expect to ship their product to Salt Lake, Utah, smelters.

It is reported that the railroad from Caliente to Pioche is to be built.—The Pioche Exploration Co., A. W. Scott of Pioche manager, have raised money to buy, equip and develop Pioche properties. They recently purchased the Mendha.

#### Lyon County.

The small quartz mill which Davidson & Lockwood have been building on Missouri Flat, near Yerington, has been completed. It will be run by water power from the Strosnider ditch and will start up the first of April. Ore from the Davidson & Lockwood mine, in Crabb district, will be worked in this mill, and custom work will be done.

#### Nye County.

The Four West Gold M. Co. has been formed at Tonopah with J. Douglas, president; W. J. Landers, vice-president, and M. R. Averill, secretary. It is the intention to sink a shaft.—J. Harris has charge of work for the Gold & Copper M. Co. at Tonopah.—Manager Wynkoop of the Liberty M. Co. says the plans for the 20-stamp mill have been drawn and he is now awaiting instructions from the home office, Philadelphia, to go ahead with its construction.

#### Washoe County.

J. Burke of Reno has leased the White Limestone mine in the Virginia range, 10 miles southeast of Reno, to the California Cement Co. for five years. Work is to commence immediately, and twenty miners and ten teams will begin operations. The White Limestone is a gypsum and quicksilver proposition. The rock is to be used in making Portland cement, plaster of paris and other materials.

### OREGON.

#### Baker County.

(Special Correspondence).—A carload of concentrates has been shipped to the Sumpter smelter from the concentrating plant at the Highland mine by N. J. Sorenson & Co. At this plant coarse concentration is desired. The Highland ores are sulphides. The ore crushed to ¼-inch size goes to a trommel screen, the first section of 20-mesh screening out the fines, which, conveyed by launders, go to the Card concentrating table which separates the values and makes the table concentrates. All material going through the remaining section of the trommel screen goes to the fine jig for jiggling treatment and comes out in three grades of concentrates: Head sieve fine concentrates, tail sieve fine concentrates, and hutch. The oversize, or all material that will not pass through the trommel screen, is led to the coarse jig, which also makes three products of coarse concentrates, namely, from the head and tail sieves and hutch. In these jigs the values settle on the screens, from which they are tapped off by an automatic spout. About 3000 tons of milling ore on the dump at the mouth of the Glasco tunnel is being run through as a test of the new plant's capacity. This ore dump was hanked up during the development of the Glasco drift and the shipping of ore while the concentrating plant was being installed. Some good assays have been had on concentrates produced from this ore dump. From six to eight tons of crude ore are concentrated into one by the process and from 50 to 75 tons per day are run through, varying with the character of the ores. The company have under consideration the installation of a 200-ton concentrating plant. The drift on the vein is in 1000 feet, the Highland crosscut 350 feet into the mountain. The drift on the vein is called the Glasco tunnel; some ore bodies have been opened up. The Highland crosscut is intended to provide the main entrance or outlet for the working and developing of the mine, and will intersect the main vein 200 feet below the level of the Glasco tunnel. It will reach a depth of 800 feet on the Bannockburn claim. At the mouth of this tunnel is to be erected the large concentrating plant soon to be placed on the property.

Sumpter, March 28.

Manager H. C. Armstrong of the Chloride mine in the Elkhorn district, near Baker City, has secured a lease and bond on the Chloride mine from the stockholders and directors and will begin development work. The bond calls for the building of a stamp mill.—G. W. Boggs of Baker City, manager of the Mayflower mine near Cornucopia, has received notice of a rich strike at the mine from Superintendent J. A. Wilson.—A. J. Ernest of Seattle, Wash., intends to begin work on the Virginia mine, near Greenhorn, by May 1. The shaft will be sunk another 100 feet before the mill is started.

The first shipment of ore from the Indiana mine, 20 miles northeast of Baker City, has been received at the Sumpter smelter. Manager J. W. Messner is driving the 100 and 200 levels. The shaft is down 275 feet. When the 300 level is reached another station will be cut out and a third drift extended on the vein.—The Bonanza mine at Geiser is to be worked by A. Geiser under a bond and lease.

The Psyche mine at Greenhorn is shipping enough ore to the Snow Creek mill to run it one shift. Owing to the spring break up, the roads are in poor condition, or the mill could be kept running night and day. A large quantity of ore is broken and stored in the mine. The Psyche has a 20-stamp mill, but no wood cut for fuel. As soon as spring opens the mill will be put in shape,

and it is expected that enough ore will be in sight to keep it running. The Snow Creek shaft is completed 100 feet below the tunnel level, making it 225 feet deep. A crosscut is being run from the bottom of the shaft to cut the ledge. A few men are stopping ore from above the tunnel level, the greater part of which is being shipped to the Sumpter smelter.—The Royal White is being operated by lessees and they are taking out some good ore from a winze below the tunnel, which they will work at the Black Hawk mine.—Gilke & Kershaw have begun piping on their Vinson creek placers.—This is the earliest by six weeks that placer mining has ever been done in the vicinity.

#### Grant County.

It is reported that W. E. Gifford of Prairie City may put in a stamp mill on the Present Need, which he is working under a lease and bond.

G. T. Smith has bonded the Gem mine, near Susanville, and has an option on the Smyres ditch and water right.—The Stockton mine is worked very little owing to litigation with the Badger Co., who claim a half interest in the property. The Badger Co. is now sinking its shaft to the 900-foot level. At the 700-foot level the ore was shipped without being concentrated. The mill is being run full force day and night. The property is in charge of E. P. Kennedy.

#### Jackson County.

The showing made by recent retorts of ores from the cinnabar mines of the Meadows quicksilver district, near Trail, has caused a revival of interests in the mining of mercury in this section. Eighty pounds of mercury to the ton is produced by the properties of the Rogue River Quicksilver M. Co. The ore reduces easily and is uniform in value. This mine has produced considerable quicksilver in recent years, but its development has been slow. A small plant is placed for development purposes mainly. The retort has a capacity of 1400 pounds of ore per day. The mine is opened to a depth of 200 feet.

A new camp called Gold Ridge is attracting attention. It is on the north slope of the Siskiyou, on upper Sucker creek, at an elevation of 3000 feet. H. Siskron made the first discoveries.—In the Canyon Creek district, near Medford, Manager Layman of the Lewis & Clark M. Co. is running an 1100-foot tunnel to tap the main ore body. He will put in an air compressor and machine drills this season, and plans to cyanide the ore.—One of the few southern Oregon hydraulic mines that has been supplied with water for continual operation this season is the Sterling near Medford, the property of L. Ankeny and N. Cook of Portland. F. E. Ankeny of Jacksonville is superintendent. It is believed that the output of the Sterling for the present season, despite the absence of rain, will be \$30,000.

#### Josephine County.

Manager C. R. Ray of the Condor Water & Power Co. at Gold Ray says that the 2000 H. P. plant is to be increased to 3200 H. P. The dam across Rogue river raises the stream until its entire volume is given a drop of 22 feet.

S. Chase, owner of the Oro Fino mine on Jump-Off Joe creek, near Grants Pass, reports that he will build a 50-ton cyanide plant at the mine this season.

The Rand Mining Co. has just completed a large reservoir, to store water for the company's placers, near Galice, which have been in operation since November. With the new reservoir they will have water to supply the giants until June.

### UTAH.

#### Beaver County.

Manager Rohlfing has put in a gasoline hoist to expedite work on a crosscut being driven on the Lulu at Frisco to cut the Horn Silver ledge.—L. Morrison is reopening the Indian Queen, near Frisco.

It is reported that work has been resumed at the Blue Bird mine at Milford, owned by E. W. Genter of Salt Lake City.

#### Juab County.

For week ending March 24 fifteen Tintic mines sent out 167 carloads of ore, about 5845 tons. The force at the Centennial-Eureka mine has been increased to 325 men. The list of shippers and number of cars sent out by each is as follows: Ajax 3, Bullion-Beck 6, Centennial-Eureka 91, Carlisa 1, Eagle and Blue Bell 7, Gemini 15, Grand Central 7, Lower Mammoth 1, Marlow-Baxter lease 1, Mammoth 13, May Day 5, Swansea 2, Uncle Sam Consolidated 3, Victor Consolidated 3, Yankee Consolidated 9.

J. C. Sullivan of the Victoria mine, at Eureka, says that a winze is being sunk from the 800-foot level and that a raise is being made from the 900-foot level. The 800-foot level on the Grand Central, through which the Victoria is being worked, is an intermediate level and consequently the management of the former property is anxious to get an opening through to the 900 level, as this will expedite development work and open up stopping ground. The last shipment from the Victoria was six loads. There is plenty of room for the storing of the ore underground and consequently it is not sent out until several carloads have accumulated. C. E. Loose is manager.—Work has been resumed by the Dakota M. Co., near Diamond. The company may buy the hoisting plant of the old Cleopatra mine at Silver City, and sink 200 feet farther. James Higginson of Eureka is in charge.—The Sweetwater mine in North Tintic will begin development.

#### Piute County.

General Manager S. M. Levy of the Annie Laurie mine of Kimberly reports the completion of the 450-foot upraise connecting the lower with the upper tunnel. When the timbering is completed all ores mined will be sent to the mill through the lower adit.

#### Salt Lake County.

Alex. Colbath, manager of the Quincy M. Co. at Alta, reports that a good body of lead ore, carrying silver and gold values, has been struck in the tunnel 1370 feet from the mouth.

The Columbus mine, at Alta, has started to cut a station on the first level below the tunnel, and, as soon as completed, will drift both ways. They have a large body of ore at this point and will have a good stoep to the tunnel level. The mill is running steadily, both

shifts. The bins are full of concentrates awaiting shipment, the roads being in such bad condition that teaming is almost impossible.—The Continental tramway has ordered more buckets, as the present number is not sufficient to work it.

After the roof of the Kempton mill at Bingham has been raised it will be started on ore from the Phoenix and from the Silver Shield.—At the Boston Consolidated at Bingham the forces have been doubled. The ore shipments have been increased from 150 to 250 tons daily and could be further increased were the smelter prepared to handle more. The Teck tunnel, which is exploring the porphyry belt, is going ahead at the rate of 37 feet per week, and the rock thus far has averaged from 1.07% to 2% copper. The Boston Consolidated has made arrangements to furnish air to the Bingham Central.—The Fortuna company has struck good copper ore in the Keystone tunnel, which has been driven on the Keystone contact 2200 feet. Superintendent J. Start is putting out twenty-five tons of lead ore daily from another vein to which it will now add shipments of high-grade copper ore. The Fortuna company has contracted with the United States smelter under which the latter secures the entire output of the mine for three years.

It is said that J. C. Montgomery of Denver has an extension of time on his option on the Ohio Copper Co.'s property at Bingham, and will continue development work.

The Utah Con. Copper Co. at Bingham is contemplating increasing the capacity of its smelter 500 tons. Its present smelter is treating 825 tons of ore per day and turning out copper bullion at the rate of 1,500,000 pounds per month. An increase of 500 tons in smelter capacity would permit the treatment of a still larger percentage of low-grade ore, and of a monthly bullion output of 2,000,000 pounds.

#### San Juan County.

A. E. J. Weyland of Spokane is in the San Juan River country, where the Great Western Oil Co., in which he is interested, owns 3600 acres of oil land. Superintendent B. D. Harshberger expects to begin sinking five wells on June 1. The company has made a contract to supply fuel oil to a New York company having placer beds in the district.

#### Sevier County.

The Copper Butte M. Co. of Richfield has contracted with W. J. Shelton for an additional 100 feet of opening in the Shelton No. 2 tunnel. This tunnel is in over 100 feet. A 50-foot shaft has been sunk. It is expected to strike a cross vein within the next 100 feet to be run at a depth of 140 feet from its exposure in the shaft.—The Perju-Surprise Co. will resume work on its properties near Richfield.

#### Summit County.

The Mt. Masomi tunnel at Park City is in 800 feet and estimated to be within 75 feet of the cross fissure. J. C. Hasson is foreman.—J. W. White has been in Park City figuring on a hoisting plant for the Nelson property in the Elkhorn district. The hoist is to have a capacity for 1000 feet.

The annual report of the Daly-Judge M. Co. at Park City shows that receipts from the sales of ore and the placing of bonds amounted to \$174,242.74. The territory has produced 14,485,411 pounds of lead, 487,879 ounces of silver and 1010 ounces of gold since first worked. Concluding his report to the shareholders, President J. J. Daly says that, in the work, about 6000 tons of good concentrating ore, besides some first-class or shipping grade, has been taken out and stored near the mill. The character of the ore found has changed for the better from that left in the old workings, from a standpoint of concentrating as well as smelting, it being practically free from zinc and carrying a good per cent of lead, silver, gold and iron values. It is the intention of the management to continue driving the prospecting levels ahead for some time yet, as they feel confident of finding one or more of those large, rich shoots of ore, such as are found in adjoining mines. During the year tests were made, in different works, on both the crude ore from the mine as well as the zinc middlings from the dumps, to find out the best method for their treatment. The work done has been principally on the 1200 and 1400 levels. The drifts have been run ahead into virgin ground, on the different levels with some crosscut work, for 5500 feet, and while this work has not as yet opened into as large ore bodies, it has passed through many small shoots or bodies of ore.

#### Tooele County.

The Overland mine at Sunshine has shut down, due, it is said, to the collapse of the 1400-foot incline shaft, through which the property had been operated. The mine has been in charge of E. W. Clark, manager of the Ophir Hill mine at Opbir.

The Honerine mill at Stockton is reducing 300 tons of tailings daily from an old dump. While the gross value of the material does not exceed \$6 in silver, lead and gold, said Manager W. F. Snyder, the simplicity with which they are handled and the few men required in the operation of the tables and Huntington's enables the company to work them at a profit, while keeping the machinery in continuous operation. The drain tunnel is in 7500 feet.

#### Utah County.

The officers of the Gold Blossom property in North Tintic have decided to double the working force and run two shifts, also to commence the shipping of ore. The first ore is expected to be on the market within two weeks. A short road to the mine will be built to enable teams to get to the mine with supplies and return with ore for the San Pedro Railway in Cedar valley.

### WASHINGTON.

#### Ferry County.

S. G. Dewsnap of Republic says he found that by grinding the Republic ores to 60 and 70 mesh, careful concentration will produce one ton of concentrates from 35 to 36 tons of ore, this one ton of concentrates carrying from 60% to 66% of the value. By carefully classifying, 90% of the tailings from the concentration can be cyanided by percolation with a very dilute cyanide solution operating through a long time, 70% to 86% of the gold remaining in the sands after concentration can be

extracted. The slimes can be briquetted with the concentrates and make a product desirable to the smelter. The cost of such treatment, if carried on a sufficiently large scale, can be brought within \$2.15 per ton of ore. While these experiments point to a possible method of ore treatment, enough work has not yet been done to carry out all the necessary details.—The Ben Hur is taking out ore for shipment to the Boundary Falls smelter. It is reported that they have a year's contract for four cars a week.—The Quilp is shipping ore.—The Morning Glory is under lease and recently a body of very high-grade ore was struck, which is being taken out for shipment.—The California is being retimbered and put in shape as rapidly as possible for further prospecting. Superintendent Case is hopeful that he may make the California a regular shipper in time.—The greatest activity of the district is on Belcher mountain, 7 miles east of Curlew lake and 12 miles from Republic. The Belcher has been developed by three tunnels cutting the ledge to a depth of 300 feet with crosscuts showing the width of the ledge to be from 70 to 80 feet. The ore is of low grade, carrying gold and silver but high in iron. On the surface the ledge is hematite for a depth of 40 or 50 feet. Then it changes to magnetite for a limited distance and then changes to pyrrhotite and pyrites. The ore carries copper from the surface, but in the lower levels some bodies of quite high-grade copper ore have been encountered.—The Gold King and Anonymous expect to begin development very soon.—The Copper Key has been shipping ore to the Granby smelter.

#### Okanogan County.

The Ben Harrison mine at Chesaw has been closed down until J. P. Blaine and W. C. Peay, superintendent and manager, return from the East.—J. Boyd, manager of the Palmer Mountain Tunnel G. M. Co., accompanied by L. H. Porter, Northampton, Mass.; E. E. Barr, Springfield, Mass.; F. G. Dunham, Holyoke, Mass., and E. W. Mudler, Cleveland, O., has been investigating the tunnel and electric power developments of the company at Loomis.

### WYOMING.

#### Carbon County.

At the head of Spring, Jack and the Savory creek sections of the Encampment mining district, the winter has been favorable and free from snow up to the last four weeks.

J. Smith is working a copper prospect at the foot of Dexter Peak. Native copper has been found in the schist, which is an unusual occurrence in this country. The development work consists of an incline run in at the foot of the hill. He states that it will be impossible to work much longer without a pumping and hoisting plant, and preliminary steps are being taken to secure one.—The Copper Bar on Spring creek has put in a machine drill.—Underwood & Walch and Sowder brothers are working the Bridger mine on top of the Continental Divide. This property is owned by J. W. Heather of Saratoga. The shaft has been pumped out, but will have to be retimbered.

### FOREIGN.

#### BRITISH COLUMBIA.

#### Lardeau District.

Nelson reports say that work has been suspended upon the Silver Cup, because of the nearing danger of snowslides; the Beatrice has been rawbiding, but the trail is growing worse; the Eva and the Nettie L. are working as usual, while operations have been resumed upon the Silver Dollar, where a tunnel has been started to tap the lead at a depth of 100 feet. Work will start upon the Mammoth as soon as the snow goes.

In describing the mines of the Lardeau, the Rossland Miner says that the Grand Solo group, on which a short bond has been given to Eastern parties, consists of the Grand Solo and Copper Peak mineral claims, which have an elevation of 4500 to 6500 feet. So far 55 feet of tunnel has been driven on the ledge, which is 4 feet wide and shows a paystreak of 22 inches of quartz and grey copper. The property is owned by P. A. Lindgren and N. Boden.—The Black Jack, Silver Dollar fraction, Clara and Grand Falls constitute the Black Jack group. A very strong quartz lead is exposed on the Black Jack, which is 10 feet wide and carries grey copper. The only work done on this claim consists in stripping the ledge for several feet. On the Silver Dollar fraction open cuts have been made and a tunnel driven for 25 feet. In the tunnel 6 inches of ore, running 210 ounces in silver to the ton, has been obtained.—The Knob Hill group is made up of the Knob Hill, Selkirk and Valley mineral claims, and adjoins the Linson View on the south, and on it are exposed the same leads at various points. Very little work has been done on this property, which is owned by N. Erickson.—Next is the Broken Hill group, made up of the Broken Hill and Selma. On these properties is a strong quartz lead 5 feet in width, with a paystreak of from 6 to 12 inches. The ore is galena. The vein has been stripped in several places. M. Nelson is the owner.—The Red Hill group consists of the Red Hill, Broker and Victoria. On the Red Hill there is an inclined shaft 25 feet. The ore is of the same grade as the Linson View. There is an 8-inch pay streak on the hanging wall, which will average \$100 to the ton. The owners of this group are Bergh, Bodin, Craig & Hillman.—The Ruby Silver group, situate at the head of Canyon creek, consists of five claims. On the No. 1 vein of the Ruby Silver a tunnel has been driven for 25 feet, showing 25 inches of ore on the foot wall. On the No. 2 a tunnel has been run for 110 feet. On the Good Shot claim of this group is an open cut for 10 feet. The property is owned by P. A. Lindgren, M. Nelson, G. Bergh and N. Boden.—It is expected that operations on the Lake, between the ports of Gerrard and Trout Lake, will be resumed about the first of April.

#### Southeast Kootenay District.

According to the Prospector, the prospects for mining in the Fort Steele mining district look better this season than any year in the history of the district. With the three big mines in the district in operation the output of silver-lead ore will be large.—The condition of mining

in the Kootenay valley will depend upon adequate means of transportation. As soon as it is officially announced that the Kootenay Central is under construction, a number of properties will commence preparatory work toward making shipments. The snow has gone, and placer companies on Wild Horse creek are cleaning out ditches and flumes preparatory to active operations. In this district properties that usually commence work in May will be in full blast before April 15th.—Manager G. E. Henderson, of the Bull River M. Co., will increase the force at Bull River. The machinery will be put in as fast as possible.

#### Slocan District.

High-grade silver ore has been struck in the Fisher Maiden, 7 miles above Silverton, on Four Mile creek, and is being sacked until it can be shipped, as the roads are now impassable.

#### MEXICO.

##### Durango.

Bernard MacDonald, formerly manager of the Le Roi at Rosslund, B. C., now consulting engineer for the Guanajuato M. Co. of Guanajuato, says that the property is producing \$135,000 a month, of which nine-tenths is silver and one-tenth gold. The property has a big stamp mill equipment and a cyanide plant is being put in. The mine work is done by natives, who are paid \$1 Mexican, or 50 cents gold, per day. These fellows do about half the work of a good American miner, and it is fair to say that mining, so far as common labor is concerned, costs about 30% or 35% of the pay in the Northwest.

J. W. Morehouse of Guanacavi has completed plans for a 100-ton smelter and concentrator which will be built at the Nueva Australia mine. L. Judd and J. T. Judd of Mexico City, who are interested in the mines, are at the property. An attempt will be made to save the copper values.

##### Guanajuato.

E. L. Dwyer's project to drain the La Luz mines in Guanajuato by means of a tunnel and to use the resultant water for irrigation purposes has been taken over by New York and Atlantic City parties.

The Peregrino M. & M. Co. of Guanajuato has purchased a 40-stamp mill. G. H. Mellhinney is interested.—The Guanajuato River M. Co. has put in machinery to dredge the Guanajuato river. The concession under which the company will work was secured from the Government by G. W. Bryant and G. H. Mellhinney of Guanajuato. The first work will be done below the Flores hacienda, in the city of Guanajuato, where the tailings of the hacienda de beneficio, belonging to the Rul family, first entered the river. The river will then be dredged for several miles downward.

##### Jalisco.

The Zapopan G. M. Co. of Guadalajara, in which C. C. Bruckner and G. E. Purnell are interested, and which owns the Zapopan and San Miguel mines in La Yesca district, proposes to run a crosscut tunnel to cut the vein of the Zapopan mine.

##### Mexico.

President Diaz has issued a decree for the reform of the monetary system as authorized by Congress in December last. The decree establishes the "peso" or silver dollar at a value of 50 cents gold and the theoretical unit of the Mexican currency is defined to be the dollar or peso of 75 centigrams of gold.—The mint will be closed on April 16 to the free coinage of silver and the new monetary system will go into effect May 1.

##### Sonora.

(Special Correspondence).—General Manager Gerber, accompanied by Manager Lockhart and Superintendent Hyde, have arrived at Tolodo under an escort of fifty soldiers and have started the 100-ton smelter recently erected there by the Yaqui S. & M. Co. M. S. McCarthy, the former manager under Gerber, who resigned to engage in personal affairs, returned for one month to the smelter to facilitate the work of getting in shape and giving his successor the benefit of past experience regarding ores of that vicinity.—H. L. Miller, general manager of Libertad, has ordered Superintendent J. W. Cleaver to close down all work on that property. Libertad was owned by R. C. Coy and other Chicago, Ill., investors, and it was on returning from that mine that both Coy and J. McKinzie, in company with Call and Stubling, met death at the hands of Yaqui Indians, Miller and Tolletson escaping.—The Mina Grande M. Co. has completed connections by tunnel through the mountain, whereby the San Pedro and Mina Grande are in shape for operation. The mines continue to show increased valuation.—The Santa Rosa mines of San Javier are working a 30-ton smelter successfully. San Javier, March 22.

(Special Correspondence).—The Gold Treasure mine, south of Naco, Ariz., is to have a 20-stamp mill. With erection of the mill a tramway 8000 feet in length is to be built from mine to mill. The Gold Treasure is said to have 6000 tons of ore on the dump at the present time, which makes an average of \$14 to the ton. In the 700 feet of work that has been done on the property, all in tunnels, enough ore is reported in sight to insure operation of the mill for a number of years. C. H. Saunders is manager. Naco, March 26.

(Special Correspondence).—Thomas Ewing of Cananea has denounced 960 pertenencias 9 miles south of Naco. A 12-foot vein of high-grade silver ore, with 4% copper, has been struck in the Vota Grande mine.—The owners of the Cachisse silver mine, near Yzabel, report having struck an 18-inch vein of ore running 2000 ounces.—B. N. Norton, superintendent of the Swansea mine, reports that the heavy rains have seriously interfered with operations in the Picacho and Bocoachi districts.—P. D. Robles has denounced two claims of 12 and 6 pertenencias near Los Conejos, in the Bocoachi district. Cananea, March 27.

Upon representation by the Yaqui Copper Co. that marauding Yaquis were endangering their property and the lives of their employees, the Mexican War Department has established a military post at Campo Santo Nino, and sent a company of troops for protection.—The Clenaguita Copper Co., owning mining properties in

the Sahuaripa district, has ordered three additional furnaces, which are to be completed by December, 1905. Plans for a 200-ton concentrating plant are being prepared, and the concentrator should be ready about the same time. Two of these furnaces will be built adjacent to the two now nearly finished on the Chipiona group, and one at the Ostimuris mine. The object in building at the latter mine, which is about 2 miles from Chipiona, is to save the expense of hauling ore to the Chipiona smelters. Work on the Ostimuris has progressed rapidly; a large body of high-grade sulphide ore is being opened.—It is reported that the Black Mountain M. Co. is putting up a cyanide plant at Cerro Prieto. H. E. Whipple has charge.

The Transvaal Copper Co. will build a railroad from the St. Nicholas mine to Campas, 18 miles northeast, where the smelting plant is now built. The smelter will be ready for operation in six months, and by that time it is expected that the road will be completed. The new hoisting plant is in operation.

The annual report of the Lucky Tiger M. Co., working the Lucky Tiger mine in Altar district, shows that during 1904 the mines produced 1095 tons of first-class or shipping ore, having a gross value of \$236,033.28, which, added to the small production of 1903, gives a total of 1326 tons produced, of a gross value of \$269,231.20, since the opening of the mines. Development work done in 1904 was 5554 feet, making a total development of 10,358 feet since the organization of the company. On the year's production the company has a net earning of \$92,482.22. The permanent improvements made on the property were a new concentrating mill, \$141,565.11; mine improvements, \$58,050.39; various improvements, \$20,072.51. The new concentrating plant was completed and started on February 2, 1905. A test of the first-class concentrates produced showed 2.12 ounces gold and 47.1 ounces silver per ton, or a gross value of about \$320 per ton. There is ample ore of the second-class variety to keep the mill running continually, and its present capacity—fifty tons per day—can be doubled for less than one-half the original cost, which will be approximately \$60,000 when all payments are completed. A plant for treating the mill tailings by the cyanide process is now in contemplation and will probably be installed within a few months. A small smelter will also probably be built as soon as the operations of the concentrator show what process of smelting will be most advantageous. In the meantime all first-class ore will be sold and shipped as heretofore.

#### NEW ZEALAND.

The most productive mining district in New Zealand is that in Ohinemuri county, where the mines at Waiki and Karangahake are the chief producers. The mines and mills of the Waiki Co. are among the largest in the world. The annual report of the Minister of Mines for New Zealand states that 1100 people are employed by this company, which treats over 200,000 tons of ore annually for an output exceeding \$3,000,000, an average of about \$15 per ton. New ground has been opened in the vicinity which promises to materially increase the output of the district. The Karangahake district employs 450 men and produces about \$1,000,000. There is considerable prospecting being done in the district. The mines in Coromandel county are of a different class from those above referred to. The veins are smaller and the values spotted (pockets), but the output from these mines in the aggregate is large. The number of dredgers operating in the West Coast, Otago and Southland is over 200. Dredging has been carried on in these districts for many years. The Minister of Mines says that during the early period of dredging on the alluvial flats in Southland there was much fear expressed that the work of the dredgers would inevitably result in the total destruction of the land. This does not appear to have been the case to the extent predicted, as on some of the lands which have been dredged vegetation has sprung up, and appears to be preferred by cattle to that of adjoining land which has not yet been disturbed. The planting of forest trees on the dredged tracts has also been attempted, with every promise of success.

#### Obituary.

GEO. W. LADD, the discoverer of the Bullfrog mines, died at Goldfield, Nev., March 26, of pneumonia.

THOMAS TELLEY, aged 74, locomotive engineer, is dead at Fort Wayne, Ind. In fifty years' active service he never injured a human being with his engine, on the Pennsylvania railroad.

W. A. TAYLOR died at Pueblo, Colo., March 20, from effects of an operation. He was an owner of the Allegheny mines and mills, near Telluride, and prominently connected with the advancement of San Miguel county.

ISAAC L. REQUA of Oakland, Cal., died at his home on March 28. He was one of the men who earned fame and fortune on the Comstock Lode in its early history, accomplishing among other great work the sinking of what is known as the Combination shaft, sunk at the joint expense of the Hale & Norcross, Chollar, Potosi and Savage mining companies. It is one of the great deep shafts sunk on the Comstock that still remains open. Mr. Requa retired from active mining life some years since to accept the presidency of the Central Pacific Railroad, an office he held for many years. He was born in 1828.

#### Trade Treatises.

The Western Iron Works of Los Angeles, Cal., sends a booklet describing their gas engine, claiming that it vaporizes and gasifies heavy fuels as well as volatile fluids.

Catalogue No. 18, of the Union Gas Engine Co. of San

Francisco, Cal., shows by illustrations the design and mechanical construction of the Union stationary engines and the improvements made in their twenty years' experience.

The Reliance Machine & Tool Co., of Cleveland, Ohio, describe their bolt threading, pipe threading and nut tapping machinery and accessories in a neat catalogue, which also contains considerable practical information for the machine shop.

#### Personal.

C. M. EYE of Trail, B. C., is in San Francisco, Cal.

ALBT. ROBERTS is now superintendent St. Ives mine, Goldfield, Nev.

S. S. GATES is superintendent Pozos mine near Ahualulco, Colima, Mexico.

H. C. LAY has returned to Telluride, Colo., from an extended Eastern visit.

H. K. WHEELER has returned to Los Angeles, Cal., from an extended Eastern trip.

SIDNEY S. REEVES is millman and assayer for the Echo M. Co., near Mojave, Cal.

W. B. DEWALL, E. M., of Denver, Colo., has been examining mines in Sonora, Mexico.

J. H. TALBOT is superintendent of the Reina del Oro M. Co. at El Tirol, Sonora, Mexico.

J. E. MCINTYRE is manager of the Rey del Oro M. Co., Magdalena district, Sonora, Mexico.

JAS. M. WHEATON succeeds C. A. Wightman as president Gavilanes M. Co., Durango, Mexico.

W. E. STEWART has taken the management McCann mine at Butte City, near Jackson, Cal.

W. R. GRACE, secretary Ingersoll-Sergeant Drill Co., has returned to New York from Butte, Mont.

MANAGER DOMMERQUE, Kellogg Switchboard & Supply Co., Chicago, Ill., is visiting California.

C. H. SISSON of San Francisco, Cal., is assayer at the Pfau mine, Cherry Creek, Yavapai county, Ariz.

J. H. KINKEAD has returned to Virginia City, Nev., from an extended trip to his interests in Mexico.

W. H. HENDRICKSON has been appointed assayer at the Bingham-New Haven mine at Bingham, Utah.

W. RYAN has been appointed superintendent Silver Shield mine at Bingham, Salt Lake county, Utah.

HARRY MITCHELL is the new superintendent Vacas San Marcos M. & M. Co., Vacas, Durango, Mexico.

W. G. PAGE, superintendent of the Red Elephant mines at Hailey, Idaho, has been in Salt Lake City, Utah.

W. H. WHITESIDE succeeds W. J. Chalmers in the vice-presidency of the Allis-Chalmers Co., Milwaukee, Wis.

E. HILTY is superintendent Pasadena Con. M. Co., working east of the Gold Road mine, Acme, Mohave county, Ariz.

M. M. KIRKPATRICK, consulting engineer D. McKenzie Co., New York, is manager Midnight Co.'s property, Goldfield, Nev.

W. M. CURTIS has been appointed superintendent American Flag mine at Park City, Utah, succeeding the late J. G. Rhodin.

C. E. GILLAN will succeed F. Taylor as superintendent Bingham-New Haven mine at Bingham, Salt Lake county, Utah.

L. PARSONS is superintendent Nevada Goldfield M. Co., in the Gold Mountain mining district, 9 miles west of Thorp's Wells, Nevada.

ARTHUR CLARE has resigned as mill foreman Ymir Gold Mines, Ltd., to take a similar place at the Nickel Plato mill, Hedley City, B. C.

J. B. HARRIS of Stockton, Cal., has been appointed superintendent Jose Gulch mine, near Jackson, Amador county, Cal., succeeding W. E. Stewart, resigned.

E. S. DAUGHERTY, consulting engineer Inca M. Co., Trapatá, Peru, S. A., via Arequipa, was in Denver, Colo., the past week and is now in New York on his way to Peru.

F. E. NORTON, of the Citizens' Consolidated G. M. Co. of Wheeling, W. Va., and R. B. Stanton of New York have been inspecting mines in the Cracker Creek district, near Bourne, Or.

JESSE F. McDONALD, Colorado's new Governor, is of a distinguished mining family, and is an old and successful miner, who thoroughly understands all phases of the mining situation and the requirements of the mining man.

WM. DAVEY has resigned as superintendent Lightner mine, Angels Camp, Calaveras county, Cal., to accept a similar position with the Tintic M. & D. Co. at the Yampa mine, Bingham Canyon, Utah, taking the place of W. J. Craig, resigned.

C. S. VERRILL, of Republic, Wash., has taken charge of the construction of the Crooked River Mining & Milling Co.'s evaporating plant at the Hogan mine, at Oro Grande. He will also have charge of the mine and act as consulting engineer and metallurgist for the company.

L. W. TRUMBULL, geologist University of Wyoming, is making an examination of the coal fields along the U. P. R. R. He will soon visit the Shoshone reservation which is to be thrown open in June, 1906, for the purpose of examining the coal fields of that region.

DR. C. D. WALCOTT, director United States Geological Survey, has returned from Ottawa, Canada, to Washington, D. C. His mission was to secure co-operative advantage in the harmonious working of the American and Canadian departments of the public service, satisfactory advance having been made with that end in view.

## Books Received.

The Geological Survey of Ohio is doing a good work in the development of the mineral resources of that State by not only showing how and where the minerals occur, but also how they may be utilized. The latest bulletin, "The Manufacture of Hydraulic Cements," by A. V. Bleining, gives one of the best practical accounts of this important branch of structural engineering yet published in the English language. It is valuable alike to the manufacturer and the consumer. The author defines his subject as a material that hardens in water as well as in air, and treats of it in four subdivisions—pozzolana cements, hydraulic limes, Roman cement and Portland cement—showing why the latter, theoretically and practically, has the greatest strength. The second chapter deals with the raw materials of each kind, being especially explicit on the slag and Portland cement industries. The chapter on the analysis and testing of raw materials is preceded by a valuable account of prospecting and sampling practice and includes technical instruction on the chemical and physical examination of clays, sands, limes and slags. An account of the manufacture of pozzolana and natural cements is followed by an exhaustive discussion of Portland cement, its nature, its raw materials, how they are most economically won and prepared and how burned and ground. This subject is handled in great detail, and, while severely technical in treatment, is eminently practical. The consumer will be interested in the methods of testing Portland cement found in the last chapter. This book gives little chance for adverse criticism, and a more general knowledge of its contents will do much to improve the quality of this important building material. Through ignorance, plants have been built in poor places and are not intelligently managed, producing thousands of barrels of poor material, whose use tends to discredit cements as a class. In the words of State Geologist Ed. Orton, the book states "what materials are needed to make good cements, what mechanical treatment is necessary and what effects will result from deviations of the prescribed quality of materials or treatment." The book can be obtained from the office of the State Geologist at Columbus, Ohio, at cost of publication or will be sent postpaid by the MINING AND SCIENTIFIC PRESS upon receipt of \$1.50.

## Commercial Paragraphs.

J. A. YEATMAN, engineer and salesman for the United Iron Works of San Francisco, is in Los Angeles, Cal., on business.

R. N. NASON & Co.'s increasing business necessitates a change. Their new address is 117-119 Market street, San Francisco, Cal.

H. M. MONTGOMERY has been appointed Chicago sales manager of Alberger Condenser Co., and has opened an office at 316 Home Insurance Bldg., Chicago.

THE Western Pacific Railway Co. now has right of way from Oroville, Cal., through the Beckwith Pass. A general construction contract has been let to W. H. Brown & Bros. of New York.

GEO. W. MYERS, 917 Hayward Bldg., San Francisco, Cal., representing the Chrome Steel Works of Chrome. N. J., reports large sales of shoes and dies during March. He is now on a business trip to New York and intervening points.

THE C. H. Shaw Pneumatic Tool Co., Denver, Colo., has appointed the Compressed Air Machinery Co., San Francisco, Cal., agents for California, Nevada, Oregon and Alaska. The Shaw Co. report the sale of drills to several parts of the country.

THE S. H. Supply Co. of Denver, Colo., report sale of a plant comprising a duplex station pump, boiler, etc., to the Weldon G. & C. Co., of Arizona, a 10-stamp mill with copper plates and power plant to California men and a 50-ton concentrating plant to Idaho.

THE Vencedora Mine Equipment Co. of San Francisco, Cal., has sold a 50-ton Vencedora bot blast smelter to a mining company in British Columbia, and another of twenty tons capacity to a Mexican company. On the order books is one of fifty tons for Missouri for smelting lead ores.

THE Fulton Iron Works, San Francisco, Cal., have shipped one 20-stamp mill and one of five stamps to Mexico, also a 10-stamp outfit for the Volcano M. Co., California. They have recently sent to the United States of Colombia, S. A., a 90-foot steel side wheel steamboat, being the first order for this class of work from that country to be filled by San Francisco works. England has heretofore controlled the business.

THE Union Gas Engine Co. of San Francisco, Cal., recently installed a 125 H. P. three-cylinder marine engine, and a complete electric light plant in the German government schooner Ponape. This engine is fitted to run on kerosene, gasoline or distillate. This company is now building two of this same type for the John J. Sesson Co. of San Francisco; two for the Pacific Shipping Co., of the same city, which are to be installed in the Argus; and two for the Albion Lumber Co., also of San Francisco, Cal. In the Auckland, N. Z., anniversary regatta, Jan. 30th, in the motor launch races for boats over 26 feet, Union engines were successful in securing first, second, third and fourth places. In the races for boats under 26 feet Union engines secured both first and second places. In the motor launch races of the Hobart, Tasmania, regatta, the launch Dart, 21 feet fitted with 2½ H. P. Union engine, won first place. The course was 6 miles long.

## Latest Market Reports.

SAN FRANCISCO, March 31, 1905.

### METALS.

SILVER.—Per oz., Troy: London, 26½d (standard ounce, 925 fine); New York, bar silver, 56½c, refined (1000 fine); San Francisco, 56½c; Mexican dollars, 46c, San Francisco; 43½c, New York.

COPPER.—New York: Standard, \$15.50; Lake, 1 to 3 casks, \$15.37½@15.50; Electrolytic, 1 to 3 casks, \$15.37½; Casting, 1 to 3 casks, \$14.87½. San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18@24c. London: £67 10s spot per ton.

LEAD.—New York, \$4.60; Salt Lake City, \$3.50; St. Louis, \$4.12½; San Francisco, \$3.70, carload lots; 4½c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5½c; pig, \$4.85. London: £12 10s per long ton.

SPELTER.—New York, \$5.87½; St. Louis, \$6.15; London, £23 12s 6d per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

TIN.—New York, pig, \$29.87½@30.00; San Francisco, ton lots, 31c; 500 lbs., 31½c; 200 lbs., 32c; less, 33c; bar tin, 35@37½c. London, £137 12s 6d.

PLATINUM.—San Francisco, crude, \$18.50 per oz.; New York, ingot, \$19.50 per Troy oz. Platinum ware, 75@82c per gram.

QUICKSILVER.—New York, \$40.00@41.00, large lots; London, £7 12s 6d; San Francisco, local, \$38.00 per flask of 75 lbs.; Denver, \$45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c. SOLDER.—Half-and-half, 100-lb. lots, 19.75c; San Francisco, Plumbers', 100-lb. lots, 16.50c.

ZINC.—Metallic, chemically pure, ½ lb., 50c; dust, ½ lb., 10c; sulphate, ½ lb., .04c.

NICKEL.—New York, 55@60c per lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c per lb.; 100 lbs., 35c; 1000 lbs. 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

### STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$16.35@16.85; gray forge, \$16.65; San Francisco, bar, 3c per lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, \$23.00@27.00; open hearth billets, \$23.00@27.00; San Francisco, bar, 7c to 12c per lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, ½c per lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LUMBER.—(Retail): Pine, ordinary sizes, \$24.00@5.00; extra sizes bigger; redwood, \$28.00@30.00; lath, 4 cts, \$4.50@5.00; pickets, \$21.00; shingles, \$2.50 for No. 1 and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00@35.00.

LIME.—Santa Cruz, \$1.25 country, \$1.25 city per bbl.

CEMENT.—Imported, \$2.15@2.65 per bbl.; California, carload lots, \$1.90 f. o. b. at works; small lots, \$2.20 per bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

### GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 7½c; Hallett's, 7½c; San Francisco, 1000-lb. lots, 9c; 300@500-lb. 9½c; 100-lb. lots, 10½c.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lot, Eastern and foreign: Wallend, \$7.50; Brymbo, \$7.50; Pennsylvania, bd., \$14.00; Scotch, \$8.00; Cumberland, \$13.00; Cannel, \$8.50; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13.00 in sacks; Sunnyside, \$8.50, long ton.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17c. No. 1\*, 60%, carload lots, 13½c; less than one ton, 15c. No. 1\*\*, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2\*, 35%, carload lots, 9½c; less than one ton, 11c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg.

CAPS.—3x, \$5.50@6 per 1000; 4x, \$6.50@7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

FUSE.—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c per set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c per lb.; carloads, 23@23½c; in tins, 30c; soda ash, \$2.00 per 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c per lb.; Cal. s. soda, bbls., \$1.10@1.20 per 100 lbs.; sks., 90c@1.00; chlorate of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@3c; powdered sulphur, 2½@2c; flour sulphur, French, 2½@—c; alum, \$2.00@2.25; California refined, 1½@2c; sulphide of iron, 8c per lb.; copper sulphate, 5½@5½c; chloride of lime, spot, \$2.50@2.75; sulphuric acid, in carboys, 66% B. 1½@2c per lb.; nitric acid, carboys, 8c per lb.

OILS.—Linseed, hoiled, hbl., 60c; cs., 65c; raw, hbl., 58c; cs., 63c; Lucol oil, hoiled, bbl., 51c; cs., 56c; raw bbl., 49c; cs., 54c. Kerosene—Pearl, per gal., 19c; As; tral, 19c; Star, 19c; Extra Star, 22c; Eocene, 21c, Elaine, 25c; Water White, in bulk, 12½c; Mineral Seal iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Minera; Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 16c, do., cs., 22½c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E. W. S., hbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 63c; Bleached, do., 57c; Whale Oil, cs., 52@57c.

BORAX.—Concentrated, 6@7c per lb.; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5@6c per lb.; No. 1, 4@5c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c per lb.

MOLYBDENUM.—Best, \$2.75 per lb.

CHROMIUM.—90% and over, ½ lb., 80c.

PHOSPHORUS.—American, ½ lb., 70c.

SODIUM.—Metal, ½ lb., 50c.

BISMUTH.—Subnitrate, ½ lb., \$2.10.

URANIUM.—Oxide, ½ lb., \$3.50.

MERCURY.—Bichloride, ½ lb., 77c.

TUNGSTEN.—Best, ½ lb., \$1.25.

SILVER.—Chloride, ½ oz., 90c@1.00; nitrate, 55c.

RED LEAD.—500 lbs. and over at one purchase, ½ lb., 7c; less than 500 lbs., 7½c.

MANGANESE.—Per lb., \$2.75.

MAGNESIUM.—Pure, N. Y., \$1.60.

FIRE BRICK.—Domestic, carloads 1000, f. o. b., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skewback, \$30.00; circle, \$32.00.

FIRE CLAY.—Domestic, ½ ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, \$8.50.

## New Patents.

DEWEY, STROUG & Co.'s SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING MARCH 21, 1905.

785,193.—LATHE—J. M. Brown, South Bend, Wash.  
785,660.—DEMILION HANDLE—W. E. Brown, Los Angeles, Cal.  
785,474.—PLOW—D. G. Burkhardt, Dayton, Wash.  
785,289.—HANGING SCAFFOLD—T. J. Campbell, San Francisco.  
785,197.—STEP LADDER—H. H. Case, Bismarck, Ariz.  
785,291.—STATEMENT AND COLLECTION RECORD—M. M. Cohn, San Francisco.  
785,602.—PRESSING MACHINE—W. H. Fisher, L's Angeles, Cal.  
785,611.—ENGINE—C. E. Hastings, Griffin, Cal.  
785,670.—WHEEL—C. H. S. Helling, Alameda, Cal.  
785,214.—EXTRACTING ORES—W. A. Hendrix, Los Angeles, Cal.  
785,215.—BOOK MARK—G. W. Hill, Brookfield, Wash.  
785,553.—PUMP—E. Hoornbeck, Riverside, Cal.  
785,423.—WOODEN PIPE—J. Hopkirk, Seattle, Wash.  
785,509.—FLY ESCAPE SCREEN—J. S. Johnson, San Francisco.  
785,556.—BRUSH SCRAPER—G. E. Kent, Ce. Italia, Wash.  
785,616.—STUMP BURNER—Keywood & Elmer, Tacoma, Wash.  
785,504.—VEHICLE AXLE—P. Le Scuer, Calabasas, Cal.  
785,315.—ELECTRIC RAILWAY—T. Mahoney, San Francisco.  
785,555.—AMALGAMATOR—P. McEntee, Spokane, Wash.  
785,267.—BASTING DEVICE—H. McPhail, Visalia, Cal.  
785,369.—PROPELLER—E. G. Meinecke, Alameda, Cal.  
785,512.—BRIDGE BIT—T. Mili an, Fortuna, Cal.  
785,635.—THERMOMETERS—J. Peterson, Tacoma, Wash.  
785,228.—LOCK—R. Phelps, Seattle, Wash.  
785,435.—AWNING—J. R. Powell, Los Angeles, Cal.  
785,330.—CHURN—S. B. Rathbun, Stockton, Cal.  
785,332.—CAKE MIXER—F. R. Schmidt, San Francisco.  
785,336.—PUMPING ENGINE—O. O. Storie, Tacoma, Wash.  
785,655.—CORSET FASTENING—H. W. Thurlow, San Francisco.  
785,584.—CAN MILK MACHINE—M. A. Wharton, San Francisco.  
785,245.—GAGE TOOL—E. Wiet, Sacramento, Cal.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey, Stroug & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

DOOR AND WINDOW FLY-ESCAPE SCREEN.—No. 785,309. March 21, 1905. Joseph S. Johnson, San Francisco, Cal., one-half assigned to Francis Cutting of same place. This invention consists of an improved screen having in combination vertical wires forming the warp, horizontal wires forming the filling of the screen, one or more of said filling wires being omitted at intervals between the top and bottom of the screen, offsets formed by bending the screen at approximately right angles, said offsets including the spaces formed by the omitted filling wires and the warp wires being separated within these offsets to form openings and strengthening ties across the offsets, a frame having the sides formed with inclines and offsets corresponding with the screen, to which frame the screen is secured, and one or more vertical tension rods extending between the top and bottom members of the frame, said rods substantially straight, extending from the inner angle of each offset across the space formed by the inclination below, and being attached again to the screen at a point contiguous with the next offset. This device permits the escape of flies from rooms, at the same time preventing their entrance from outside.

CAKE MIXER.—No. 785,332. March 21, 1905. F. R. Schmidt, San Francisco, Cal. This invention consists in the combination of a container inclosing a circular chamber, a rotary dasher or mixer concentric with said chamber and mounted on a horizontal axis, said dasher including a plurality of radially supported rings, cross wires connecting said rings, cross rollers supported between said rings and movable in close proximity to the interior of the chamber, radially disposed removable scrapers carried by the dasher and adapted to engage the sides of the container, said container having an ingress passage and a closure for said passage, said closure having a bottom section sloping downwardly in the direction of rotation of the dasher, the lower edge of said incline, bottom being substantially continuous with the inner periphery of the mixing chamber and means for rotating the dasher.

OUTSIDE HANGING SCAFFOLD.—No. 785,289. March 21, 1905. T. J. Campbell, San Francisco, Cal. This invention consists in the combination of a plurality of outriggers provided with means to attach them to a fixed part of the framework, bars suspended from said outriggers, the latter and said bars having corresponding perforations, a U-shaped clip slipped over an outrigger and the end of a corresponding bar and a pin or bolt passed through said perforations, said U-shaped clip serving to relieve the strain of said pins or bolts on the outriggers, brackets carried by said suspended bars and a flooring or equivalent carried by said brackets, and other details of construction, all adapted to bring about the desired result.

ELECTRIC RAILWAY.—No. 785,315. March 21, 1905. T. Mahoney, San Francisco, Cal. This invention comprises in an electric railway system the combination with a motor car of a sectional trolley rail and a sectional conductor abreast of said trolley rail, a switchbox disposed relative to each trolley-rail section, a solenoid in said box, a feeder, a core reciprocal in said solenoid and adapted to close the circuit between the feeder and trolley rail and to carry the motor circuit, current collectors on the car contacting with the trolley rail and the outriggers, the sectional conductor collectors in constant electrical connection with the return irrespective of the direction of travel, and an actuating circuit shunted off from the motor circuit and passing through a solenoid, thence across to a corresponding section of said sectional conductor up into the car through said sectional conductor collectors to return.

COMBINATION STATEMENT AND COLLECTION RECORD.—No. 785,291. March 21, 1905. Max M. Cohn, San Francisco, Cal. This invention consists in a combination statement and collection record comprising original and duplicate sheets, said original sheet having a reserved area designated for the customer's name, a reserved area designated for the account and an intermediate area printed with the merchant's name, and said duplicate sheet having reserved areas registrable with the said areas of the original sheet which are designated for the customer's name and the account, and having, also, an area registrable with the said intermediate area of the original sheet, provided with notation in permanent form which is resorted to by the collector to indicate the disposal of the account.

## United Verde Fire.

The press dispatches report that the United Verde mine at Jerome, Ariz., is again on fire. The mine caught fire about two years ago and a large amount of money has been expended in efforts to control it. Bulkheads were built in various portions of the mine where it was calculated it would arrest the progress of the fire and confine the gases of combustion to limited areas. A few days ago a terrific explosion occurred on the 300 level of the mine, which resulted in the death of several miners and the injuring of a number of others. The explosion was attributed to the infiltration of surface

United Verde Mine, Jerome, Arizona.

The Mill at Cananea, Mexico. (See Page 220.)

water to the region of the fire, where a large volume of steam formed, with the result stated. The destruction of the bulkheads gave access to fresh air and the fire began to make rapid progress again. At one time a carbonic acid plant was installed at the United Verde and a large volume of this gas was sent into the mine, but the effect was only temporary. In such instances the only known method by which a fire may be completely quenched is by flooding the mine, and this expedient at the United Verde is considered impracticable, owing to the scarcity of water. When the sulphide ore in a mine takes fire, either spontaneously or through being ignited by flames from burning timbers, or otherwise, it is almost impossible to extinguish the fire as it passes into the solid rock mass beyond the reach of the direct application of any method to extinguish the fire. No flames appear with a fire of this description; the rock simply smoulders for months and sometimes for years.

ALTHOUGH the mining laws governing Alaska are the Federal Statutes, there is no essential difference between these laws and those governing the location of mining claims in the United States. Much complaint is made of the so-called "blanket locations," made in Alaska—that is, wholesale locations of creeks or other territory by other persons than the actual locators themselves. In some States the legislative bodies have enacted laws which require a stated amount of work to be performed on each claim within a limited time—sixty to ninety days—and this, to a great extent, prevents wholesale location of mining ground by any but bona fide locators who intend to develop their claims. Alaska has no Legislature, but the act extending the mining laws to Alaska contains among other provisions the following, in section 26: Citizens of the United States, or other persons who have legally declared their intentions to become such, may locate, occupy, and work mining ground in Alaska, under such reasonable rules and regulations as the miners in organized districts may have heretofore made or may hereafter make, governing the temporary possession thereof for exploration and mining purposes until otherwise provided by law; provided further, that the rules and regulations established by the miners shall not be in conflict with the mining laws of the United States. Such being the case, it seems reasonable that the miners of a district may themselves make rules and regulations which will require a stated amount of work on each claim located within limited time, but they can in no manner restrict the number of locations that may be made by one person.

## The Smelter Fume Problem.

The creation of sulphurous and arsenical fumes is an accompaniment of all smelting operations where the ores contain sulphide, antimonial, arsenical and other volatile compounds. In some districts the damage from fumes has led to the introduction of various methods for rendering them harmless. The most common practice is to make sulphuric acid as a by-product of the smelting operations. This is based upon the fact that water will, under proper conditions, absorb a large volume of sulphurous fumes. Fortunately, in many cases, the acid thus manufactured finds a ready market at a price which makes its manufacture profitable, or a portion of the acid may be employed in some other branch of the metallurgical establishment, as in leaching the oxidized ores from upper levels, or that which has been partially roasted.

It is not always convenient nor profitable for smelting concerns to engage in the manufacture of acid, as it is sometimes impossible to find a market for the product. Within the past few months this problem has been prominently brought before smelting companies throughout the West, usually in the form of court injunctions, with accompanying suits for damages. In Colorado, near Durango; at Butte, Mont., Keswick and Vallejo Junction, Cal., and in the Salt Lake valley, Utah, this has been the unpleasant experience. In each instance, excepting that at Keswick, Cal., where the complainant is the Government, against the Mountain Copper Co., the plaintiffs have been the farmers who own property in the vicinity of the smelters. So serious has the matter become, and so evident is it that the complainants can cause the metallurgists much trouble, that it is not unlikely that some new method of disposing of sulphurous and other damaging fumes, less expensive and less cumbersome than that of acid making, will be introduced. At Butte, Mont., the construction of a stack several hundred feet in height, connected with the dust chambers of the furnaces by a flue of great size, and half a mile in length, has accomplished something in the way of condensing some of the fumes, such as those of arsenic and antimony, which are sublimated in the chambers and flue and form a by-product of value, but the sulphurous fumes are less easily controlled and do not condense so readily. The most destructive fumes are those resulting from heap roasting, a method of preparing sulphide ores for smelting, which has the advantage of economy, but as the fumes rise in dense clouds directly from the ore heaps, and are not carried away by the winds from the tops of tall chimneys, and thus, to some extent, dissipated by the winds, the damage is greater than in the case of stacks. Heap roasting is not now practiced to a great extent at American smelters, though at one time an important feature of metallurgical operations at Keswick.

NO profession requires so broad and complete a knowledge of scientific and practical subjects as that of the mining engineer. In addition to having acquired a comprehensive knowledge of practical mining in all its branches, he must have had a thorough grounding in mathematics and have had training in civil engineering, mechanical and electrical engineering, and in chemistry and metallurgy. Besides this, he should have a knowledge of other languages than his own—chiefly Spanish, French and German. In addition, he must have had training in geology, physics, architecture, natural and social sciences, practical business experience and, above all, he must be endowed with a substantial amount of what is usually spoken of as common sense.

THE first trains have passed through the noted Simplon tunnel recently completed beneath the Swiss Alps, joining Italy and Switzerland. It is stated that in the central section of the tunnel the heat was found terrific, nearly suffocating the passengers. This high temperature is due to the large volume of hot water flowing from crevices cut in the excavating of the tunnel, and which gave so much trouble to the engineers at the time. Unless proper ventilating means can be found to reduce this temperature, the tunnel driven through the mountain at such great cost is likely to be less popular than was expected.

COMPARISONS are being made between the cost of Chinese labor and native labor in the mines of the Rand in South Africa, and these figures show somewhat to the disadvantage of the Chinese. In making such comparisons it is essential to know all the respective conditions in the mines compared. Though two mines may adjoin, the underground conditions and equipment may differ in essential details which will make a marked difference in the cost of mining. One mine may practice sorting and the other may mill all the rock broken in the stopes, or the most of it. In this case the tonnage hoisted and milled will indicate that the mine that does no sorting is doing the cheaper mining, but the result in gold produced per ton milled may show largely in favor of the mine where sorting is practiced. The fairest test of relative value of Chinese and Kaffirs or any other two classes of men, as workmen, is the cost sheets of the mine as operated by these two classes of men, separately at various times, when all other considerations are equal. The Chinese are replacing Kaffirs in the mines of the Rand, and not white men, as many suppose. It was only owing to the inability of the mine operators to secure a sufficient number of native laborers that Chinese were put into the mines at all, as an experiment. There are some branches of mining which require skilled white miners, and these places neither Chinese nor Kaffirs can ever hope to fill. There is abundant opportunity for white miners on the Rand who are skilled in timbering and machine work, but it would be unwise for white men to go to South Africa without a contract with some reliable company.

IN his annual report to the stockholders of the El Paso mine, Cripple Creek, Colo., the president says: "So effectively has the El Paso drainage tunnel done its work of draining Cripple Creek district, that a movement is on foot looking to the construction of another and deeper tunnel, which will drain the camp about 750 feet below the present water level. \* \* \* This tunnel will cost approximately \$300,000, and will require about two years to complete it, but it will give ten years' work to those mines embraced within the area drained, without having to pump water. \* \* \* I am in favor of a new tunnel, and propose to ask your board of directors to contribute liberally toward its cost." This is a spirit well worthy of emulation, and it is thought that the opposition to the new tunnel will gradually disappear, as the project takes more tangible shape. There can be no doubt of the great benefit the proposed tunnel would be to the district. If the mines are enabled to operate for a period of ten years without pumping, for a cost of \$300,000, it is not the tenth part of the cost of what pumping would be, and a division of the expense of driving the tunnel among the mines of the district that would be benefited by it would make the cost to each individual mine so small as to be a matter of little consequence.

ELECTRICAL engineers have met with such pronounced success in their undertakings, overcoming so many obstacles and disproving the adverse criticism of pessimists, that they now look forward with confidence to the successful operation of transcontinental lines of railroad. It is thought that there is sufficient latent power in the falls and streams of the mountains through which such roads will pass to supply the necessary power to not only carry the trains over the mountains themselves, but across the intervening valleys as well. A leading electrical magazine says on this topic: "Electric railways for transcontinental purposes can come into existence as soon as the practical pressure at which they can be worked can be settled."

THE size and cost of a tailings plant, to work an old dump by cyanidation, should be considered with reference to the amount of material to be treated and the probable profit which may be derived from the operation. More than one large cyanide plant has been installed, to learn that the available material, at the profit possible per ton worked, could never pay for the initial cost of the plant, to say nothing of a net result, and there are those which can not pay a profit on the working cost. This state of affairs is chargeable to the engineer who advised the operation and, perhaps, also designed the plant.

## CONCENTRATES.

OWNERS of mining property are not ordinarily responsible for damages done by lessees of their property.

THE charge of ore that may be treated in a chlorination barrel is variable—according to the size of the barrel.

TUNGSTEN ore is being successfully reduced at the 20-stamp mill of the Wolf Tongue Co., Nederland, Boulder county, Colo.

PYRITE has a commercial value of about \$5 per ton in large quantities at San Francisco, Cal. It is used in making sulphuric acid.

LARGE electric magnets are employed in handling iron and steel castings, forgings, etc., in many large foundries and machine shops.

MOLYBDENITE has been successfully concentrated in Canada by means of electro-magnetic separators. It is difficult to concentrate by other means.

COINAGE in the new Denver, Colorado, mint will begin July 1, 1905. A description of the coining machinery to be used appeared in the issue of Nov. 12, 1904.

TALCOSE ORES and those containing a large amount of clay may be crushed better if first subjected to calcination, which drives out the water held in the ore.

DOLOMITE is a magnesian limestone and not an eruptive rock. Dolorite is a coarse-textured basaltic rock, and has been confused with the former term—dolomite.

PLACER DIRT that runs 50 cents per ton where sufficient water and dump (good grade for tailings to flow away) are available should pay well, under experienced management.

NO SINGLE COPIES of this journal, issued prior to Jan. 1, 1866, can in future be supplied. With some few exceptions a copy of any issue since Jan. 1, 1866, can still be furnished.

AN old machine drill, no longer serviceable in the mine, may often be found still good enough to make a shop trip hammer to forge drills and other large pieces, and for general use.

WHAT is known as No. 9 tunnel of the Sierra Buttes mine, Sierra county, Cal., is in 7000 feet and cut the vein 3000 feet below the apex of the vein, on the dip. It is one of the longest tunnels driven for the operation of a mine in California.

GRAPHITE makes a good lubricant for stamp stems. Care should be taken to keep the graphite from falling into the mortar. Careful millmen cover the tops of their mortars, the stamps rising and falling through holes cut in the cover, which is in two sections.

IT is proposed to place an 80-inch searchlight on the summit of Mount Hood, Or., to be used during the Exposition at Portland. It will cost about \$30,000 to do this. The only object stated is that of producing some unusual electrical effects as an Exposition attraction.

IN England disused shafts of coal mines are sometimes used by shot makers in place of towers, the rent being much cheaper than the interest on the cost of a tower. In many shallow coal pits which have been abandoned vegetable gardeners make profitable use of them for garden plots.

WHERE ore is hard and flinty, and very fine crushing is necessary to free the gold from the gangue, a large stamp duty cannot be expected. It is the duty of the millman to secure the best economic results. He must get the greatest possible capacity with the least possible loss in tailings.

EXHAUST steam may be utilized in many ways, effecting marked economies. It may be employed to heat boiler feed water; to heat the drying room; to heat the water for the miners' bath and lavatories; to dry ore; to heat mills and other buildings; to create ventilation by draft, and in many other ways.

SETTLING CONES and other forms of hydraulic classifiers are usually made with slopes of about 50°. There is no absolute uniformity about this angle, however. In most large plants where classifying cones are used the slope angle of the cone is steep in the smaller sized cones, becoming flatter with increasing diameter of the classifier.

THE capacity of the ordinary dredge of present use is from 2000 to 3000 cubic yards per day, when working at depths from 40 to 60 feet. The capacity of any dredge is generally greater in shallow diggings—15 to 20 feet—than those dredging to 50 and 60 feet. The cost of operation is variable, but ranges from 6 cents to 10 cents per cubic yard.

THE rainfall in the foothill region of the Sierra Nevada mountains, in California, from 1863 to 1883, ranged from 17.28 inches in 1863-64 to as high as 102.22 inches in 1871-72, the general run being from 35 to 74 inches. In 1867-68 it was 99.70 inches at North Bloomfield. The average for twenty years was nearly 60 inches per annum.

IN some instances where pyritic smelting is practiced a small amount of coke is charged to aid in keeping the ore from settling too solidly on the zone of fusion. In a furnace of large capacity the weight of the column of ore is considerable, and with some ores—particularly those containing much fines—the ore may pack so solidly as to retard the running of the furnace.

THE first safety fuse was invented by William Bickford, a Cornishman, in 1831. This original fuse was much the same as that manufactured to-day. It consisted of a thread of powder around which was spun jute yarn. The fuse was water-proofed by dipping it in coal tar. In these later years a water-proof tape is wound around the fuse in single, double or triple layers.

THE city of Toronto, Canada, is preparing to install a pumping plant, the main feature of which shall be a triple-expansion flywheel pumping engine having a daily capacity of 6,000,000 imperial gallons. The imperial English gallon contains 277.274 cubic inches; the standard United States gallon, 231 cubic inches. The imperial gallon is equal to ten pounds avoirdupois of pure water at a temperature of 62° F.

IT is not always safe to assume that a smooth, wall-like surface in a vein is actually a wall, for as good ore, if not better, may lie just on the farther side of it. This applies particularly to ore occurrence in massive rocks, such as porphyry, andesite, granite, etc., but it is also applicable to slate and schistose rocks. Many good ore shoots have been missed or long laid untouched because the miner did not crosscut his country rock.

SEVERAL YEARS of experimenting in numerous gold districts has proved that slimes and sands can not be satisfactorily worked together in any leaching process, but that by separating these two products of the mill by hydraulic classifiers the two may be treated separately, and usually satisfactorily. The sands by percolation, and sometimes the slimes also, through the filter press, is often used in the treatment of the latter.

"CONCENTRATES" has heard of an instance where, in a 40-stamp mill, after standing idle for months, on being started up, nearly one-half of the stamp stems broke off just above the boss head within a week, and several others before the month had elapsed. Stamp stems sometimes break when the guides are not properly adjusted, and again without apparent cause. The reason for the remarkable breaking of stems in the mill above referred to was not stated.

ONE-INCH steel hoisting ropes are heavy enough to hoist ordinary mine loads from 1500 feet. The rope is always at its best when new, and the longer it is used the smaller grows the factor of safety. Ropes also deteriorate when wound on the hoisting reels and remaining idle for long periods. It is then practically impossible to properly lubricate them, and any moisture present is likely to cause the wires to rust. Serious accidents have occurred upon resuming the use of hoisting ropes which had long been idle.

A DUMP OF MATERIAL from a mine placed, or allowed to accumulate, on the land of another, becomes the property of the party owning the land where such dump is allowed to accumulate and remain, and the owner of the land may convert to his own use such dump material—sand, rock or ore. On steep mountain sides, where the rock dumped from a mine car or other vehicle rolls down the slope upon or across the land of another, the only damage that can be collected is for injuries actually sustained to improvements. Such injury consists of filling existing workings, damaging buildings and endangering lives and other property.

THE origin of petroleum is still a subject about which there are many theories. At one time it was supposed by some geologists to be due to an accumulation of fish and animal oils. Others believe petroleum to be of vegetable origin, and still others think it of volcanic origin, though the votaries of the latter theory do not make it clear how the oil originated. A late theory is that petroleum is due to chemical action taking place in the rock strata beneath the surface. It is a mooted question. Even in the regions where oil is found it is generally confined to a definite stratum, though in some regions there are two or more strata yielding oil.

AS TO which is preferable, a shaft or tunnel, as the main working outlet of a mine, the surrounding circumstances and conditions must determine. The tunnel has the advantage of much lower first cost per foot, and usually also of cost of maintenance. The tunnel also drains everything above its level, and greatly aids ventilation—particularly if a connection be made by raise with the surface. The relative length of tunnel to depth of shaft should be considered, as well as the cost of hoisting plant and operation of the same. There are many instances where a tunnel ten times the length of a shaft

to reach the same depth would be justified by the results accomplished through the medium of the tunnel, although the first cost of the tunnel is possibly from two to three times greater than that of the shaft.

WHEN drilling through sedimentary rocks composed of beds of a few inches thickness each, but of greatly varying hardness, the miner is often obliged to tamp holes already drilled with pieces of rock; but this gives an unsatisfactory result. It is better, when the thickness of the hard layer has been ascertained, to drill deep enough into it to break that stratum only, removing the soft rock underneath by picking, when the next hard layer found below may be treated in like manner, by drilling block holes, which will result in breaking the hard stratum only. Formations of this description are found in some Cambrian rocks and are particularly abundant in Lawrence county, S. D., on Two Bit gulch, Squaw creek and in the Spruce Gulch section.

THERE are three main uses for fluorspar. The highest grade, which runs less than 1% of silica and is white in color, is sold either ground or in lump for use in the enameling, chemical and glass trades. The second grade of spar is used in steel making and is sold unground as lump or gravel. It includes colored spar and may run as high as 4% silica. It is demanded for openhearth work in smelting because of the great fluidity which it gives the slag. The lowest grade of spar, including all running over 4% silica or spar mixed with calcite, can be used in foundry work, and while the price is always low, there is possible a large market. In some cement manufacturing concerns fluor is used to aid in making the "clinker," which it does owing to its easy fusibility.

THE amount of water necessary to properly concentrate a ton of ore depends upon the character of the ore and its gangue. Under ordinary conditions about 2000 gallons of water are used per ton of ore, though in some cases, as at some of the Butte, Mont., concentrators, it runs up to 5000 gallons per ton of water. The ordinary stamp mill requires about 800 gallons per ton crushed in the battery and from 200 to 400 gallons added on the concentrators. At Park City, Utah, F. W. Sherman is concentrating 400 tons of ore every twenty-four hours with the use of twenty to thirty gallons of water per minute, or only 700 to 800 pounds of water per ton of ore. This is in the concentration of slimes. The ores carry silver as sulphide and chloride associated with iron, lead and zinc.

TIN SULPHIDE is of comparatively small importance commercially, the greater part of the tin of commerce being obtained from cassiterite (the oxide). Stannite, the sulphide, is roasted to free it from the sulphur. It is then mixed with charcoal in a furnace and smelted. The first product of this operation is an impure alloy of tin, which is reheated slowly and the metal drawn as soon as it melts, this first metal being much purer than the alloy from which it is obtained. Tin has a very low melting point (230° C.) and if heated to a high temperature will boil and take fire, and the white oxide thus formed passes away and is lost, therefore it is advisable to have the furnace well under control. A certain amount of the tin present always combines with the silica of the furnace linings to form slag.

IN sampling a mine the only correct way to estimate the value of a block of ore is to take samples, uniform in character at stated and not too great distances. This distance is generally about 5 feet. Samples should preferably be taken with a maul, and the size should be determined by the length of cross-section of the vein from which the sample is taken. Thus if a sample from a place where the vein is 12 inches wide weighs five pounds, one from a place where the vein is 24 inches wide should weigh ten pounds. This is the natural result of cutting all sample channels of uniform width and depth. The samples having been taken, sacked and numbered, the assays when made, together with the width of the vein where the respective samples were taken, furnish the basis for estimate. The addition of the values of all the assays, divided by the sum of all the widths of samples taken, will not give the correct result. Each sample must be written in feet, or decimals of a foot, and the assay result in dollars multiplied by this width in feet. The total result of all the dollars obtained by this multiplication is then divided by the total width sampled in feet, and the quotient is the average value per foot of width of the vein. If there were three samples taken, No. 1 is 3 feet, assays \$4 = \$12; No. 2 is 2 feet, assays \$6 = \$12; No. 3 is 1 foot, assays \$10 = \$10. The sum 1 foot, 2 feet and 3 feet (the several widths taken) is 6 feet. The sum of \$12, \$12 and \$10 = \$34, which divided by 6 feet = \$5.66 = the average value per foot of width at the places sampled. Each block must be sampled, measured and the estimate of quantity and value made separately, and the whole added for gross result. The sampling of a large mine is a difficult and tedious job and requires unusual care, even if there are none of what may be considered moral hazards, among which are salting of the ore in place; salting of the samples as they are taken; salting of the sacks before or after the samples have been taken. It requires constant vigilance, and if hasting has to be done in a mine having rich and spotted values the difficulties are increased, for the sampler is likely to salt himself unintentionally. Known rich streaks should be sampled separately and estimated accordingly.

## Electricity Applied to Mining in California.

Written for the MINING AND SCIENTIFIC PRESS.

One of the most interesting mining regions in California, both mineralogically and geologically, is the territory embraced within the holdings of the Mariposa Commercial & Mining Co., in Mariposa county, Cal. It comprises over 44,000 acres—about 70 square miles—most of which has been classified as mineral land. The tract has been variously known in the past as the Mariposa Grant, the Fremont Grant and Mariposa Estate. The grant extends 2 or 3 miles along the Merced river, in the neighborhood of Bear Valley, southerly to a mile or two south of the town of Mariposa, a distance of 17 miles. Its width is variable, being from 2 to 12 miles wide, averaging about 5 miles. Within this area are found an interesting series of rocks, most of which are identified with the ore deposits of the gold belt. The principal rocks are clay slates, schists and graywacke of the Mariposa beds, slates and schists of the Calaveras formation (Paleozoic), great masses of serpentine and intrusions of diabase, diabase-porphyrite, diorite, felsite and other intrusives and a large area of diabase tuffs, much of which is altered to amphibolite schist.

Throughout the entire area are scattered gold-bearing veins and ore deposits, the most marked feature being the aukerite masses of the Mother Lode, which has its southern terminus in this tract, near the old village of Bridgeport. The mineral territory is not confined to the boundaries of the grant, but extends beyond it on all sides.

Pocket mines, occurring under a variety of geological conditions, are an important feature of the mining industry in this section. These mines have produced several millions of dollars, the Mariposa mine alone being credited with more than a million dollars from pockets, beside a large amount from milling ores. The Oso mine, near Bear Valley, is credited with a production exceeding \$400,000 from pockets. Many other mines of lesser note produced large amounts. Some of the pockets were superficial and many hundred thousands of dollars were recovered at nominal expense in the neighborhood of Bear Valley, Princeton and Mariposa.

The principal mines of the grant were the Mariposa mine, at the town of Mariposa; the Princeton and Mount Ophir, near Mount Bullion postoffice, formerly called Princeton, and the Pine Tree and Josephine, near the Merced river, north of the town of Bear Valley.

Beside these were many others, including the Green Gulch mine, near Princeton, and the Oso and Mexican, near Bear Valley. The most noted mine on the grant was probably the Pine Tree and Josephine. This property is on the Mother Lode and has all told several miles of development work. One tunnel run on the Pine Tree vein is in over 5000 feet and is at present being driven ahead and other work done there. Shafts are sunk in this tunnel and other extensive development work done.

Near the summit of the mountain, where the vein outcrops in great masses of red and brown iron oxide, traversed in all directions by veins and masses of quartz, thousands of feet of drifting and crosscutting have been done from tunnels and crosscuts driven in from the surface. In the years succeeding 1860 the Pine Tree and Josephine produced gold bullion from \$60,000 to over \$350,000 annually for several years.

The pay ore was found scattered along the great lode in a series of pay shoots. Seven of these shoots were developed and worked during the early history of the mines, but of recent years these mines have been practically idle until lately. There still remains a large amount of ground to explore, but the great size of this property alone makes the undertaking one of considerable magnitude, requiring much time and money.

The Princeton mine has been the largest producer on the Mariposa estate, that mine having produced over \$1,000,000 working to a depth of 600 feet. After making this record, the mine was closed down for many years until 1899 when it was reopened, under the direction of J. H. MacKenzie. When working in the 60's the Princeton mine yielded over \$90,000 per month for a long time. The richest ore came from within 100 feet of the surface. It paid \$70 per ton in milling rock, beside a large amount in rich specimens, few of which, it is said, having been seen by the company. The vein has a beautifully banded structure, and consists of white granular quartz, divided into ribbon-like plates. Evidently it represents, to some extent, the replacement of the slate rock in which it occurs. The sulphides are principally pyrite and galena, the gold being most abundant in the ore carrying galena. Much of the gold was found beautifully crystallized. The mine

has now been reopened several hundred feet below the former workings and a 50-stamp mill is kept employed on ore from the newly opened ore shoots. There is a large amount of quartz all about the Princeton mine, particularly on the western or foot-wall side of the vein, where there are innumerable

veins and veinlets of quartz for a distance of 1000 feet. Some of these veins are gold-bearing.

The Mariposa mine is near the town of Mariposa. At the south end the vein occupies a single fissure and is from 2 to 12 feet wide. The quartz is often crystallized, affording many handsome specimens of

rock crystal. This portion of the vein is in diabase-porphryite, much decomposed and soft near the surface, but hard and tough and of a dark green color, with phenocrysts of plagioclase in depth. Near the main shaft, which is sunk on an incline dipping to the west, the vein splits, and slates are found in contact with the vein. Near this split large pockets of gold were found by the early miners. In the veins beyond the fork the gold is more evenly distributed, but west of this fork the vein produced chiefly pockets, the intervening quartz being practically barren of gold. In depth, however, this mine has developed several shoots of payable mill rock. A 20-stamp mill is in operation on this mine.

The mines of this property mostly lie in a high valley between the Bear Mountain range on the west and Mount Bullion range on the east. There are few perennial streams in this area, which is from 1200 to 1500 feet higher than the Merced river, a stream of variable but good size in even the lowest stage of water. This peculiar situation has rendered the development and operation of these mines somewhat more expensive than in some more favored sections of the gold belt of California, but the existing conditions have been modified by the installation of an electric plant.

A year ago California stood second in the United States in the utilization of electricity for electro-motive purposes and recent developments of her wonderful water power show that she may soon be first in this country. Dredges, hoists, compressors, pumps, underground locomotives, rock drills and lights are now dependent upon electricity in many mines. The greater part of the power so used is supplied by large distributing companies with central plants generating thousands of horse power. In addition, many of the mines have put in independent plants of smaller capacities. These are usually run by impact water wheels, but as editorially suggested in a recent issue there is also a large field for the use of the turbine.

The electric equipment of the Mariposa Commercial & Mining Co. offers a typical example of the latter. It was put in because of the large and increasing demands for fuel at the different mines of the company and its increased cost per cord. Consequently, in July and August, 1901, a dam and power house were put in at Bagby on the Merced river. The power is generated by four McCormick turbines, in two pairs of 27 and 30-inch size, direct-connected by flexible leather linked couplings to a 400 K. W. three-phase Westinghouse type 2B generator. The turbines have a total capacity of 730 H. P. when all four wheels are operating under a 25-foot head, and a capacity of 600 H. P. under a 25-foot head. During low water periods when the wheels are called upon to operate under a 29-foot head, the maximum amount of power is obtained from 3000 cubic feet of water per minute. The generator has a speed of 240 r. p. m., 7200 alternations, 30 poles, an e. m. f. of 440 volts, and at normal rating gives 525 amperes per terminal. This generator is designed to run at a full load efficiency of 93%, with such regulation that with 525 amperes per terminal, 440 volts e. m. f., and 100% power factor, there will be a rise of 8% e. m. f., if the load is thrown off; and when running at 90% power factor the separately excited field current will be 15% greater than when carrying the same armature current at 100% power factor. The excitation of 65 amperes at 100 volts is secured by means of a 15 K. W., 125-volt, compound wound, multipolar generator, running at 600 r. p. m. The exciter is driven by means of a pair of 9-inch McCormick turbines, mounted in one case, provided with a 30-inch thimble, and discharging into a common draft tube. These are similar in all respects to the main 30-inch turbines—that is in regard to the necessary regulating gates which in this case are operated by hand. The exciter and its turbines are directly connected by means of flexible leather link couplings, bored and keyed to the turbine shaft.

From the power house the current is transmitted at 1500 volts to substations at the Princeton and Mariposa mines, 9.2 and 15.7 miles respectively. Each is equipped with three 75 K. W. transformers, primary voltage 15,000, secondary 450, 475 and 500. The power from the Princeton substation is used to light the Princeton mine and mill and the town of Mt. Bullion, and to run seven motors ranging from 3 H. P. to 150 H. P., aggregating 318 H. P. These motors run the 50-stamp mill, air compressor for the mine, machine shops and pumps. At Mariposa the power is used in lighting the Mariposa mine, mill and town and in running the air compressor, 20-stamp mill and pump.

The plant has been in full operation since the first of June, 1902. The power curve for the time of operation shows the rate of fall of the river during the summer, and the minimum amount of water available is usually toward the end of October, but 35 cubic feet per second flow in the whole river being a minimum. The dam has been strengthened and repaired a number of times. The plant is provided with auxiliary steam power to tide over the dry season and to be used in case of accident.

The duty of shift bosses is to keep the time of the workmen and to see that the men do not shirk their duty, but they have also to look after the distribution of tools, timbers and other supplies.

## A Graveyard Shift Below.

Written for the MINING AND SCIENTIFIC PRESS.

The experience here detailed is that of a single shift in sinking in a vertical shaft, and it will doubtless be found by many miners to be merely a recitation of their own personal experiences under somewhat similar conditions.

The "graveyard shift" went on at 11 p. m. and quit at 7 o'clock the following morning. We were working three eight-hour shifts, with three men on each shift. The hole was down 300 feet—a small double-compartment shaft, about 7x12 feet outside the timbers. The shaft made about 3000 gallons of water in twenty-four hours as a general thing, but occasionally we would hit a pocket or reservoir of water that drove us out for a day or two, and sometimes for a week at a time, until the pump could control the water. It was a nice place to work, if it were not for the fact that the water was icy cold, and plenty of it, the rock hard as steel and often fissured by invisible seams that set at naught all our calculations as to how the ground would break. We carried full shaft sets throughout, notwithstanding the hard ground, for, although it was firm enough, there were frequently treacherous seams of talcy mineral that caused the otherwise solid rock to cave at times.

On this particular occasion the bulletin at the surface contained the following, which, as the saying is, was "short and sweet:"

"Ten holes fired. Nine gone. Look out for missed hole. Muck and timber. STEWART."

Which, being interpreted, meant that ten holes had been drilled, charged and spit by the preceding shift and that they had been able to distinguish but nine reports. The orders were to muck out the broken ground and then put in a set of timbers, or make a start at it. For some reason the crew on the previous shift had gone before we arrived at the mine and there was no one to give us other information than that contained on the bulletin in the shaft house. Stewart was a sort of shift boss on the former shift. We climbed onto the bucket with our picks, shovels, hammers and gads and were lowered into the hole by the engineer. When about 20 feet from the bottom the bucket stopped and two of us got off and climbed through a hole in a side bulkhead and proceeded to lower the suction hose, which was suspended from above by block and tackle. When the upper end came in position, we attached it to the pump and rang for steam. Meantime the third man had been lowered to the bottom and had worked out a hole at one side for the suction. He was standing half way to his knees in water.

With much hissing and groaning and some bucking the sinker got down to work and rapidly drained the water so we could see the broken rock filling the bottom of the hole.

"Where does all this kindling wood come from?" asked one of my companions.

We looked up the shaft and saw a post had been knocked out of the last set and was lying back in the corner, resting on the lower plate, but in such a position that it threatened, if in the least disturbed, to fall on our heads.

The bucket was rung down and a zinc tag hanging to the cable was smoked with a candle, and then Sam O—scrawled with the point of his candle stick, "Send down a 'studdle' and 2 pieces lagging." The bucket was rung up—1 bell followed by 2 bells, a pause, and 2 more bells, which was our way of telling the engineer to look for a message. The pump continued to work away, and we dug a deeper hole for it in the muck, and shutting off steam for a minute shifted it over to the new "sump." In about five minutes the bucket came in sight and in it was a post—one of the regular size used in the set, and two lagging. With the latter we made a small platform and attempted to put the post in place, but it could not be done without easing off. I sent up a message, "Send down shaft wrenches." After a few minutes the bucket returned with the wrenches. We had been endeavoring to ease off the wedges so that the set could be pounded down about a half inch, and after unscrewing the hanging bolts a little we finally got the post in place and drew the bolts up tight, pounded the wedges back again until everything "rang like a bell."

The next thing was to begin mucking. It did not look like a very big pile, evidently the last round had not broken well. We went at it and sent up four or five buckets. At one corner we had exposed solid rock, and we were beginning to "look out for the missed hole." It is not exactly the most pleasant thing in the world to contemplate—a missed hole—even when you have located it; but to be picking around in the bottom of a wet shaft, several hundred feet below the surface, the only light that of the spluttering, sickly, yellow flames of three candles, almost extinguished by the falling mist and drops of water, makes the job a delicate one. The work must go on, however, and there are plenty who are not only willing, but anxious to do it. At first the miner is momentarily fearful of striking it and being blown into "kingdom come," or crippled for life, but

in time he becomes accustomed to missed holes, the same as to the other manifold dangers of his calling, and he takes a missed hole as one of the episodes in his life as a miner, and, though more cautious, is not less industrious.

We continued mucking until, as the empty bucket came below, I stepped away and close up to the wall at one side of the shaft. While standing thus, watching the slowly descending bucket, whirling as it came down, a small rock struck me on the hand. It came from somewhere overhead. I looked up, but could see nothing in the uncertain light. The bucket was dragged to one side, and we commenced to shovel in the rock from the bottom of the shaft. Jim R—was working on the same side as myself. Suddenly he stopped shoveling and gazed up into the blackness overhead. I looked at him enquiringly and he said, "Damme, somethin' 'it me." I said, "yes—a piece of rock fell on me a minute ago." Just then a shovelful of small stuff and a chunk of rock, weighing about 10 pounds, fell just back of me, near one corner of the shaft.

"She's comin'," said Jim, and in a twinkling he, Sam and myself made a jump for the bucket, but as it was drawn well to one end of the shaft, I knew it would swing to the opposite end if a bell were given to hoist, unless some one steered it.

I rang 3—1. In a few seconds the cable grew taut and the bucket was slowly lifted and swung under the hoisting compartment. Small quantities of the rock continued to fall from one side of the shaft, back of the plate. We all got on the bucket, which put our hands just in reach of the hanging bolts of the first set. I reached out toward the bell line. Just as I grasped it, down came nearly a ton of rock into the shaft. In a twinkling all three of us were up on the timbers, and climbing for dear life on the bolts from set to set, seeking a place of safety.

For about two minutes rock and timber continued to fall, and then all we could hear was the clack of the pump and the dripping of the water. We relit our candles and surveyed the darkness below in hope of being able to estimate the amount of damage and the probable continuance of the caving of the ground. As there was no further sound of falling rock or lagging, we finally climbed down to the last set and found that all of the lagging on the east side had gone down, and with it a ton or two of rock from behind the set. It was a wedge-shaped mass extending the full length of the shaft. It looked dangerous, and neither of us felt like taking any extra risks. After sitting awhile on the timbers, clinging to the bolts, and watching for further evidences of a continuance of the cave, we decided that the only thing to do was to get a timber and fit it in back of the set, lace it up with lagging and fill up the hole.

Jim went on top, got an extension "measuring staff," and we carefully measured the length of the hole. Then Jim and Sam went up, while I remained to watch the cave. In about twenty minutes down came the bucket with an 8-inch log hauging beneath it. I steered the log to one end and the bucket landed on the bottom. Sam cut a hitch at one end, standing on the lowest wall plate and using a pick. The ground was soft about the seam that had caused the cave. We finally put one end of the timber in its place and the other end was lifted and pulled up. I stood on the bottom, while Sam and Jim worked above on the timbers. I held the log above my head, my arms outstretched to their full length. Sam had to cut a little more because the piece would not go into the hitch. Meanwhile streams of ice-cold water trickled down my arms beneath my shirt and, following down my shoulders and ribs, began to fill my gum boots. I stood it as long I could and then called out, "Hurry up! I can't hold this all night." "Ow you gettin' on, son?" said Jim. "Hurry up!" was all I could say, as, with chattering teeth, I held up my log. Finally they relieved me of the weight and the end was fitted into the hitch and wedged up. I had about a gallon of water in each of my boots and was soaking wet from head to foot. I grabbed hold of the cable and managed to get my feet up higher than my head and most of the water ran out of the boots. We then laced up the cave by inserting the lagging which had fallen out, and leaning a line of stout sticks from the pole we had put in, to the wall back of the cave. As the lagging proceeded we threw about half a cord of wood, sent down from the surface, back of the lagging and so filled up the hole. When this was all done we went on top and ate our lunch and returned to the shaft and put in the remainder of the shift mucking out. We did not find a missed hole, as in all probability two holes had gone at the same instant and the explosions been counted as one. We got the timbers and materials down for the next set, but had no time to put them in before going off shift. "Time" did not come around too soon.

There were many such shifts in sinking this shaft. If it was not one thing it was another—always something unusual and unexpected happening. It seemed to me that there were no two shifts just alike. We worked both single and double-handed in this shaft. The single-handed man drilled the squaring-up holes, when they were necessary—and that was often, owing to the contrary manner in which the ground would often break. If no block holes or hitches were required, the single man drilled at one end of the shaft, while the "double team" polished the steel at the other end.

## A Typical Lake Superior Copper Mill.

The mills used for many years in the Lake Superior copper region form a class by themselves, and differ in many respects from those usually found in gold and silver mining regions. There are two main reasons for this. One is that the low grade of ore produced by the Lake mines necessitates a large capacity for economic reasons, and the other reason is that the peculiar class of ores of that district permit the employment of these mills, which have not, as yet at any rate, found favor in the eyes of precious metal miners. The following description of the

The entire plant—mill, boiler house and trestle approach—is of permanent steel construction. The foundation walls are of sandstone rubble masonry; the trestle and interior foundation piers are of concrete. The mill building and boiler house are of steel frame construction, with steel roof trusses; the walls are of timber sheathing, covered with corrugated iron, and the roofs are of plank with magnesia covering. The columns are I beams and built-up H sections, the latter being used for small columns where the width of I beam flanges would be insufficient.

The boiler house contains five 250 H. P. water tube boilers, set in three batteries. The mill equipment consists of four steam stamps, a horizontal tandem-compound Corliss condensing engine, with cylinders 13x36 and 23x36 inches; a 28x14-inch

ding engine parts. The roof is high enough to allow the trolley to lift a stamp engine cylinder and carry it over the cylinders of the other stamps.

Water for all purposes, amounting to approximately 10,000,000 gallons per twenty-four hours, is obtained from a reservoir formed by a steel dam on the Salmon Trout river. The head of water from the dam to the supply tank is 17 feet, and to maintain a uniform head the water flows into a standpipe, connected to the service tank by a pipe with valve for regulating the supply of water and the water level in the tank.

The steam stamps or stamp mills have cylinders 20x24 inches. Each stamp strikes 108 blows per minute; the weight of the striking parts is 2½ tons. The mortar of each stamp weighs

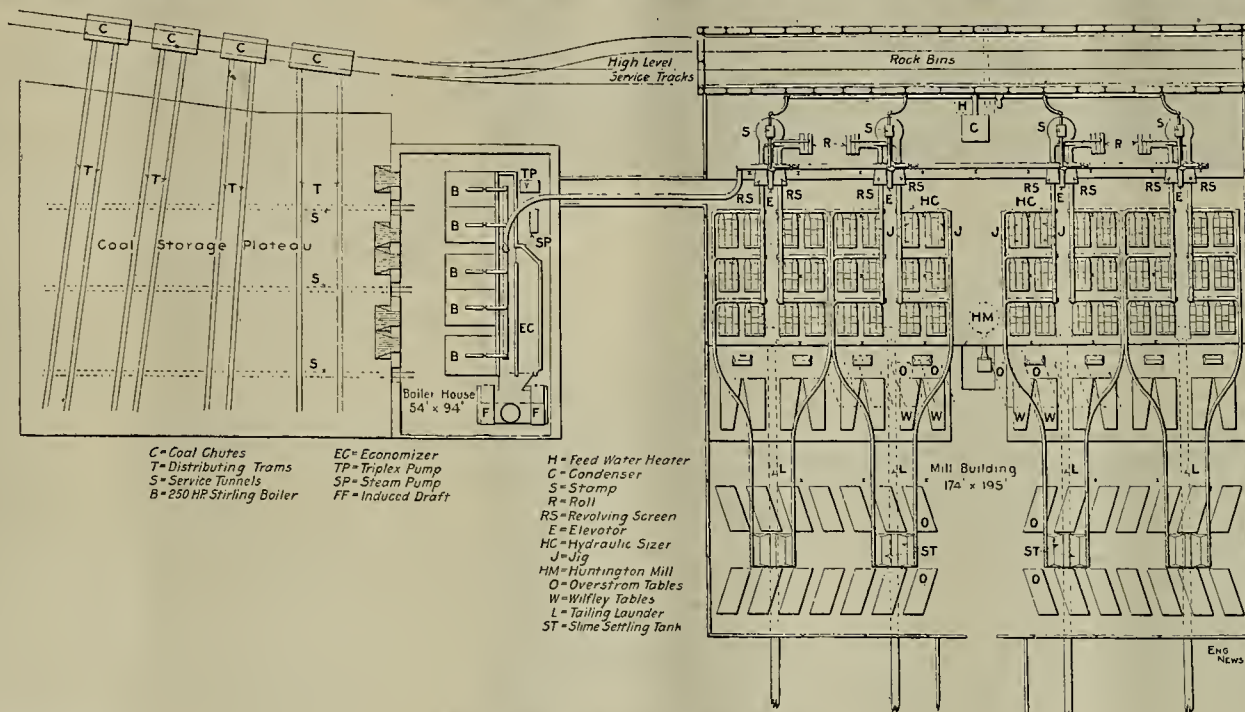

Fig. 1.—Plan of Baltic Mill, Redridge, Mich.

Fig. 2.—Cross-Section of Baltic Mill, Redridge, Mich., Showing Stamps and Concentrating Machinery.

new mill of the Baltic mine is abstracted from the Engineering News:

The recently completed Baltic stamp mill at Redridge, Mich., handles the rock from the Baltic mine, owned by the Copper Range Consolidated Co. It is typical of the modern milling plants which have been erected in recent years by various mines in the district, and is a good example of modern stamp mill design. The accompanying illustration is a plan of the plant. The rock is delivered into the rock house or bin on the upper side of the mill. Water is supplied from a reservoir, and after passing through the mill flows across the beach into the lake. The plant was designed by F. G. Coggin, superintendent of the stamp mills of the Baltic Mining Co., who also supervised the erection and now superintends the operation of the Baltic, Atlantic and Champion mills.

double-belted condenser, and a 54-inch by 14-foot feed water heater. The engine drives the jigs, concentrating tables and all mill machinery, as well as a 30-K.W. direct-current, direct-connected generator. A marine set of 4 K. W. is provided for use when the engine is not at work. Each stamp is provided with an auxiliary Sturtevant centrifugal roll 36x5 inches. The complement of concentrating machinery for each stamp consists of six four-spigot hydraulic classifiers, twenty-four double-compartment eccentric roughing jigs, four Wilfley and seven Overstrom concentrating tables. A regrounding plant consisting of one 6 foot Anaconda type Huntington mill, with seven Overstrom concentrating tables, is located in the basement. All piping for the jigs is laid under the floor. A trolley hoist on an I beam runway over the stamps is provided for han-

13 tons and rests on cast iron anvil blocks weighing 87 tons, which in turn rest on concrete foundations. These foundations are piers 20 feet square and 32 feet high, founded on bedrock. The concrete for 22 feet from the bottom is in proportions of 1 part Portland cement to 3 parts sand and 5 parts stone; for the upper part the proportions are 1:2:4, and this upper part is reinforced by sheets of wire screening—¾-inch wire and 2-inch mesh. These sheets are 1 foot apart, vertically.

The usual practice has been to place timber cribbing under the concrete or between the concrete and the stamp mortar, in order to absorb shock and vibration, but this also absorbs some of the force of the blow. At the Baltic mill there is no provision for elasticity, the mortar being anchored solidly to the concrete and the concrete built directly upon

bedrock. It is, of course, necessary to anchor the mortar very rigidly to the concrete, as any play or lost motion would cause the stamp to batter it to pieces. With this arrangement less steam is required to crush a given amount of rock, or more rock can be crushed with a given amount of steam, than where provision for elasticity is made in the foundations.

In the operation of the steam stamps, to produce a blow sufficiently heavy, the valves are set for a late cutoff on the top end. On the bottom end only sufficient steam to raise the stamp shaft needs to be admitted, so that by far the larger volume of steam is used on top. It will be evident, also, that the effect of the vacuum may be removed from the top end without impairing the striking efficiency of the stamp. Advantage is taken of this fact to secure the exhaust steam required to heat the mill and the feed water. The top and bottom exhausts of each stamp cylinder are independent. A free exhaust main leads through the feed water heater to the atmosphere, and a condensing exhaust main to the condenser. The piping is so arranged that either end or both ends of the stamp cylinder may be run condensing or non-condensing, as desired. In normal operation three stamps run full condensing; in the fourth the exhaust is divided, the top steam going to the feed water heater and the vacuum on the bottom exhaust being still maintained. The only loss attending the large gain is the small amount of steam which is needed on the bottom end to offset the absence of vacuum on top.

In the steam lateral leading to each stamp is a large receiver separator, so that the steam at the stamp throttle is practically dry. The feed water is taken from the condenser hot well at 110° F., leaves the feed water heater at 200° F., and goes by gravity to a tank in the boiler house, in which are also collected all the trap discharges from the steam main and receiver drainage system and the heating system. The triplex pump takes its suction from this tank and delivers the feed water through the economizer into the boiler at 300° F.

The rock is delivered from cars of 42 tons capacity into bins in the rear of the stamps which have a capacity of 2600 tons, above the level of the discharge openings to the stamps. Below this level the bins are filled with waste rock. The arrangement of the mill is such that from the time the rock is dumped until it is delivered as crushed tailings at the other end of the mill all operations are conducted by gravity.

Each stamp is equipped with a mortar provided with screens having  $\frac{1}{4}$ -inch round perforations, and the product through these screens is delivered first upon revolving screens having  $\frac{1}{4}$ -inch round perforations. The screenings from the latter go at once to the concentrating machinery below. The material too large to pass through the revolving screens was formerly returned by an elevator to the mortar of the stamp to be further reduced, thereby greatly reducing the capacity of the stamp. According to practice first introduced in the Baltic mill, this material is now elevated to an auxiliary Sturtevant roll, with which each stamp is provided, and there sufficiently reduced to pass through the revolving screens.

When the pulp has all finally passed the revolving screens it first goes to hydraulic sizers, which deliver four sizes of relatively coarse material, and an overflow containing the finest material, technically termed "slimes." The coarse material is delivered upon jigs. These are boxes kept continually filled with water and consisting of two connecting compartments, in one of which a horizontal screen of 8 to 12 mesh is set about 3 inches from the top, and in the other of which a vertical plunger operates. The sized material flows across these screens and forms a bed upon them. The action of the plunger, forcing water in regular pulsations through this bed, so loosens it that the released copper, by reason of its greater specific gravity, sinks to the bottom and there collects, while the lighter gangue (or rock) is forced over into the tailings or waste. The copper is then automatically removed. Material made up of copper and sand fine enough to pass through the screens is continually passing through the screens on the jigs into the compartment underneath. This material is continuously drawn off, settled in settling tanks, and the settled material delivered upon tables called "finisher" tables. These tables have a plane horizontal surface, approximately rectangular in form, covered with linoleum. This surface is given a longitudinal accelerated reciprocating motion, having a slow forward throw and a quick return. The surface has a slight incline to one side and a thin film of clear water is allowed to flow transversely from the upper to the lower side. The material above mentioned being delivered on the head of the table, the action is such that the heavier copper settles, clings to the surface and travels ahead, while the sand, more or less in suspension, is swept to the side and away. The copper travels the length of the table and is removed. The jigs are placed in a series of steps at the rear, while in the front are the concentrating tables.

In the "tailings" or waste from the jig screens is a considerable quantity of coarse particles which contain copper not released. This material, called "middlings," and amounting in the mill to about 50 tons per twenty-four hours, is automatically removed from the screens before it can get into the waste

and taken to the Huntington mill, where it is ground fine and treated on tables similar to those just mentioned. The slimes or overflows from the sizers are conducted to settling tanks, and the settled material treated on tables similar to those mentioned.

The sources of fine (in size) copper in the mill are, therefore, the jig screens, the finisher tables, and the slimes tables. In addition to these are several sources of coarse copper: (1) Masses picked from the rock before it enters the mortar of the stamp; (2) nuggets of virgin copper varying in size from a filbert to a coconut, which are taken directly from the mortar of the stamp by means of a hydraulic discharge, and consists of a pipe, with proper valves, leading from the interior of the mortar to the outside, through which a stream of water under high pressure is injected into the interior of the same, the force of this stream being so graduated that the heavy copper drops into the pipe, while the lighter gangue (or crushed rock) is kept back; (3) nuggets of smaller size, which are discharged by similar hydraulic discharges located in the launders or flumes leading from the stamps to the sizers. These various products go to make up the mill yield of "mineral," which is shipped in steel cars to the smelter.

**RESULTS.**—The mill was originally designed to handle 2000 tons of rock per twenty-four hours, or 500 tons per stamp. The addition of the rolls has increased this to over 600 tons. The stamps require 300 boiler H. P. each, and the driving engines 150 H. P.

Pittsburg coal showing an average of 13,000 British thermal units per pound is used. In the boiler house is a permanent equipment for the testing of boilers, and the plant under working conditions shows an evaporation of 9.5 pounds of feed water per pound of coal and at 212° F.

The rock treated in the mill contains approximately 27.5 pounds of metallic copper per ton of rock, or 1.07% by weight. Of this, 21.5 pounds are recovered and 5 to 6 pounds lost in the tailings. An 80% extraction is, therefore, indicated. The cost of milling the rock is between 18 and 20 cents per ton.

### Electric Air Drill.

One of the latest electric rock drills to be placed upon the market is the Temple electric air drill which is operated by means of compressed air at moderate pressure transmitted through short flexible hose from a small compressor run by an electric motor. The compressed air does not exhaust into the atmosphere, but is retained in the system, requiring a minimum expenditure of power.

The compressing apparatus consists of a small double cylinder air compressor bolted and geared to an electric motor. The compressor has no water jacket and but two small valves. All the gears and bearings are enclosed and run in oil. The drill has practically but one moving part—the piston. A rotating device is used to operate the piston instead of the pawl and ratchet.

According to the statements made by The Hendrie & Bolthoff Manufacturing & Supply Co., Denver, Colo., the drill has been thoroughly tested in actual work in the mines and it is believed will find a ready market. At present the machine is being made in two sizes. The smaller one requires 3 H. P. to operate and the larger one 5 H. P. to run. The drill strikes 400 to 450 blows per minute, 7-inch stroke.

In the 3 H. P. size the compressor and motor weigh 150 pounds each. The drill also weighs 150 pounds. In this size machine the compressor is mounted on the motor, the latter serving as a base. In the 5 H. P. size the compressor and motor are mounted together on a small truck, the entire outfit weighing 850 pounds, which can be run on the usual mine track and placed on and off the track by two men with a bar. Both size machines, it is claimed by the manufacturers, can be operated by either direct current or alternating induction motors, of whatever standard voltage may be available and desired, either 110, 220 or 440 volts, 220 volts being adopted as the standard whenever practicable.

Temple Electric Air Drill.

The engraving herewith illustrates the drill ready for operation. The shell is similar to that of the ordinary air drill, so that any standard  $\frac{1}{4}$ -inch column or shaft bar can be used.

The bit used in these drills consists of a cross bit, the cutting edge of which forms an obtuse angle. This is upset, so as to give plenty of stock back of the bit, with the result that a hard temper can be utilized without danger of the bit breaking.

The drill is being manufactured and placed on the

market by The Hendrie & Bolthoff Manufacturing & Supply Co., Denver, Colo. They will send a descriptive Bulletin No. 5, explaining more fully the machine, to any one requesting it.

### New Portable Balance.

The accompanying illustrations show a new portable button balance just placed on the market by Wm. Ainsworth & Sons, balance manufacturers of Denver, Colo.

This balance is of the columnless type, constructed to withstand a moderate amount of rough handling. It has a 5-inch beam, agate edges and bearings, fall

Portable Balance, Type R.

Portable Balance, Types R and N, With Carrying Cars.

away pan rests, and is made with either single or double rider apparatus. An improved locking device locks the beam in position on the balance for carrying. The balance is operated from the left hand end and has concealed leveling screws of improved design. Two level vials are placed in the base, instead of a single circular level as sometimes used. The case is of French polished mahogany, and a carrying case of the same material is provided with a leather carrying strap, lock and key. A combination of the portable button balance with a portable pulp balance in a single carrying case forms a compact and convenient prospecting outfit. All parts of the pulp balance pack in the drawer. Full particulars are given in portable balance bulletin, sent on request by the manufacturers.

### Munificent Gift to Mining Men.

Several months ago Mr. John Hays Hammond, E. M., conceived the idea of donating to the service of his fellow workers in California, his former home, a technical library, chiefly devoted to mining and metallurgical subjects, to be placed in some easily accessible public place in San Francisco, Cal. To this end he has placed in the hands of Mr. Chas. G. Yale of San Francisco the sum of \$5000, and has appointed as trustees, to carry out his wishes in this regard, Mr. Chas. G. Yale, Mr. Louis Janin, E. M., and (ex-officio) the State Mineralogist of California, and has selected the State Mining Bureau in San Francisco as a suitable repository for this valuable collection of technical literature. The gift has been made without those conditions which too often subvert the wishes of the donor of such gifts, as well as embarrass the trustees in their desires to do the things which to their minds are proper. The desire of Mr. Hammond is to establish a library of technical works which shall be of value to the professional mining and metallurgical engineer, the superintendent and the miner, as well as others who may be interested in the mining industry. The matter of the selection of books and equipment is left entirely to the trustees above named. The provision is made by the donor that under no circumstances shall the library be removed from the city of San Francisco, but in the discretion of the trustees may be placed elsewhere than in the State Mining Bureau, should occasion arise. It is the intention to purchase suitable cases, desks and other necessary furniture, to secure the desirable books, to have such as require it suitably bound, and to completely catalogue the collection so that the literature in this collection may fully serve the purpose for which it is intended. The trustees will at once assume the responsibilities of their trust, and the library will be established as soon as practicable. This gift of Mr. Hammond is but the initial donation, he having signified his intention of following it up with what further contribution may be necessary to make the library a complete success.

## The Mines of Cananea, Mexico.\*

NUMBER II.—CONCLUDED.

Written for the MINING AND SCIENTIFIC PRESS.

The reduction works of the Cananea Company comprises an extensive power plant, mill and concentrators, smelter and converting plant, with all the accessories to the mining and reduction of the ores of the company. The accompanying illustrations show the extent of the metallurgical plant. One feature of the plant is the frequent extensions and enlargements made to keep pace with the increasing producing capacity of the mines as development was extended. In 1902 the concentrator had a capacity of 600 tons daily, but the plant has since been greatly changed and enlarged and the capacity increased to over 1000 tons in this mill, and a new one has been built during the past few months, which still further increases the output.

The various processes in concentration at this mill were thus officially described by Dr. Ricketts, who reconstructed the concentrating plant: "The work of reconstructing the concentrator was carried out in sections, half of the mill being operated while the other half was being built. A substantial ore bin, of a capacity of 3000 tons, will be built south of the present mill for storage of iron from the mines, and, in connection with this bin, a screening and picking system will be installed.

"Adjacent to these ore bins a new crushing plant will be built for crushing all the ore to size required for preliminary concentration. From the crushing plant the crushed ore will be carried to the receiving bins for each concentrator by a system of conveyor belts.

"In the concentrator twenty-eight jigs will be installed in addition to the four now in use. A vanner house, 38x210 feet, will be added, in which there will

\*See illustration front page.

Electric Haulage at Cananea, Mexico.

be placed thirty-six vanners, and two fine-grinding machines will be installed.

"In the present mill the concentrates are elevated to storage bins on a level with the receiving bins by a system of conveyors, and then loaded into cars by another set of conveyors. This is unsatisfactory, particularly in view of the large tonnage of concentrates—500 tons per day—which will have to be trans-

ported to the smelter when both units are running at full capacity.

"In the face of the large expenditures in the enlargement and reconstruction of this mill, the results expected are of interest. The Veta, Maude and Capote ores are simple ones to concentrate, being easily crushed and easily concentrated. The method proposed involves no radical departure or experi-

The Old Concentrator, Cananea, Mexico.

The New Concentrator, Cananea, Mexico.

The Smelter at Cananea, Mexico.

ments, but is strictly in accordance with successful practice in the treatment on a large scale of ores somewhat similar to these, but less amenable to concentration.

"The results that will be accomplished by these changes are as follows: The capacity of the mill will be increased to not less than 24,000 gross tons per month, including allowance for delays. The mill tailings accurately sampled will contain less than 1% copper.

"Cost of milling will be reduced to 75 cents per ton of ore or less.

"The net increase in value of ore treated over present practice will be fully \$1.70 U. S. currency per ton, with copper at 13 cents in New York. This allows 4 cents per pound for winning the refined copper from the additional concentrates that will be saved, and allows for a loss of 10% in smelting."

### The Leyner Rock Terrier Drill.

The J. Geo. Leyner Engineering Works Co. of Denver, Colo., has brought out a light-weight drill

rotating the steel. The steel is rotated as the feed screw is turned, by means of a positive gear connection between the chuck and a sleeve covering the feed screw. This feature makes it almost impossible to rifle and fitcher a hole in the seamiest kind of ground."

The manufacturers further say: "Before these drills were put upon the market, they were placed in several mines in Colorado for several months and accurate record of the work done each day was kept. It was found that they will drill 30 to 45 lineal feet of holes in five hours, including setting up, changing and taking down—depending upon the nature of the rock. The holes drilled were from 1½ inch down to 1 inch in diameter and up to 5 feet in depth."

A full detailed description can be had by addressing the company.

### Of Interest to Miners.

Chas. G. Yale has received from the head office of the United States Geological Survey at Washington, D. C., a copy of every annual report, monograph, bul-

Leyner Rock Terrier Drill—Dry Pattern.

for use in all kinds of work, with the exception of heavy tunneling and sinking. They claim that for stoping and upraising it is especially suitable. It is called the "Leyner Rock Terrier Drill," and is made in two styles—the dry pattern and the water pattern. The dry pattern is only recommended by them for holes above the horizontal; they assert that the water pattern can be used for holes of all kinds, as hollow steel is used, through which air and water in combination are forced for the purpose of cleaning the holes of the rock cuttings.

"Either drill can be changed to the other in a few minutes by the exchange of a few parts and the exchange of steel. The dry pattern has a total of nineteen parts, with one moving part, and weighs 54 pounds, and the water pattern has a total of twenty-seven parts, with one moving part, and weighs 56 pounds. Both drills have cylinder diameters of 1½ inch and consume 25 cubic feet of free air per minute. The mounting used is a column or bar of 2-inch inside diameter, which would make the total weight of the complete equipment, including the drill, mounting and steel, extremely light.

"A unique feature of the machine is the method of

Fig. 1.—Gold Separator and Amalgamator.

ter, and forms an air space, the bottom or L of the riffles turned up at each end and brazed, to hold quicksilver in the bottom of each riffle.

The upper riffles C, made of wood or other substance, but preferably of copper, are held in place by holders which set on top of the holders holding the under riffles, and are placed above and extending down between the top of the lower riffles, the tops of which are bent back with the flow of the water; the bottom is bent toward the flow of the water, with intent to hold the quicksilver in the bend or L. The gold, sand and water pass through the riffle boxes underneath the riffles C, and over the under riffles D, passing into the riffle box at A, filling to the top of the first upper riffle, and then passing under it. Further information regarding the machine can be had from the manufacturer.

### THE PROSPECTOR.

The rock samples from the Mount Hope mine, near Grizzly Flat, Cal., are practically identical, one sample being massive, the other slightly schistose. It is a metamorphosed sedimentary, apparently, though this is difficult to determine from a hand sample. The principal minerals are feldspar, with a little quartz. The brownish color is due to the innumerable small plates of brown biotite (mica). The schist also contains a small percentage of iron sulphide. It is not uncommon to find this rock, which belongs to the Calaveras formation in California, gold-bearing in the East Lode section. The description of the occurrence of the rocks which accompanies them is complete and interesting. It is desirable that all who send samples give as full information as possible.

The light ash rock from Boca, Nevada county, Cal., is volcanic ash and consists of thin plates, threads and grains. It might be useful as an abrasive, or polishing material. It contains no diatoms visible to a magnifying power of 600 diameters. The material is not fuller's earth, as on moistening with water it proves to be slightly plastic.

The rock from Roseburg, Or., is a vesicular dolerite, in which there is a large development of hornblende and olivine. The vesicles are lined with chalcidonic quartz.

The rock specimen from Burris, Cal., is an aggregate of tremolite crystals (a variety of hornblende). It is somewhat altered.

The rock specimens from Selma, Cal., are: No. 1. Dolomite. No. 2. Chalcedony and novaculite. No. 3. Smoky quartz crystals. Neither of these samples is of value. The smoky quartz to be of value must be free from flaw.

The mineral from Nome, Alaska, and mailed from Seattle, Wash., is barite, or heavy spar (sulphate of barium). Its specific gravity is from 4.3 to 4.6. Sometimes used as an adulterant.

The rock samples from Dillon, Mont., are: No. 1. Soft red rock, clay, stained with red iron oxide (hematite). No. 2. Hard, blackish brown rock, with conchoidal fracture, limonite (iron oxide).

THERE are mines at Butte, Mont., which have been burning for several years. The St. Lawrence, one of the noted mines of Butte, has been burning for about twelve years. No attempt is made to extinguish these fires further than to build bulkheads. To flood the mines of Butte is deemed out of the question for the reason that the water would in all probability do more damage than is being done by the fires, and it would in many cases be impossible to flood one of the burning mines without flooding others where there is no fire, and this would not be permitted. A mine fire under ordinary conditions where the timber burns is serious, but where the rock itself supports a fire which cannot be extinguished, the results are far more reaching than in any ordinary mine fire.

Fig. 2.—Gold Separator and Amalgamator.

## Mining and Metallurgical Patents.

PATENTS ISSUED MARCH 28, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

LIQUID FUEL BURNER.—No. 785,271; W. F. Richey and T. Daly, Paris, Tex.

Liquid fuel burner comprising chamber having tube for admitting steam entering it near one end of chamber, liquid fuel inlet within tube, means for mixing fluid and fuel comprising tortuous passage surrounding tube, and having outlet near end of chamber at which tube enters chamber.

APPARATUS FOR EXTRACTING METALS FROM THEIR ORES.—No. 785,214; W. A. Hendryx, Los Angeles, Cal.

In ore-treating apparatus, combination of tank, tank-supporting frame, discharge aperture in tank provided with valve seat, valve operatively supported in valve seat, valve stem secured to valve, means for supporting upper end of valve stem above tank, means for operating valve; tubular propeller shaft surrounding loosely valve stem, casing surrounding propeller shaft, ball bearing and collar for supporting shaft and pulley secured to shaft, with gland stuffing box on top of shaft, and mounted on and provided with suitable packing arranged to pack valve stem and to close opening in shaft.

GAS PRODUCER.—No. 785,955; F. W. Johnstone, Mexico, Mexico.

Gas producer, combination of vertical fire cham-

ber, open-bottomed retort depending therein throughout major portion of its height, means for supplying fuel to retort, means for raising fuel which passes out of bottom of retort into surrounding fire chamber space between walls of producer and retort, and gas discharge pipe leading out of upper portion of fire chamber.

COOLING JACKET FOR BLAST FURNACES.—No. 786,180; D. Baker, Newton, Mass.

In blast furnace and in combination with bosh wall, cooling jacket surrounding same and provided at its lower end with horizontal flat annular plate forming continuation of outer surface of jacket and having its edge terminating beyond body of furnace, plate adapted to receive without interruption water flowing downward over exterior of jacket and adapted to permit it to be discharged freely outward, and receiving trough sustained free of furnace wall vertically beneath discharge edge of plate in position to receive water flowing over plate.

DREDGE.—No. 786,253; I. G. Gillespie, Oak Harbor, O.

In hydraulic excavator, conduit for excavated material, having downward bend near its forward end, brackets supported by conduit, pair of shafts journaled in brackets, agitator on each of shafts adjacent to inlet of conduit, hood for inlet of conduit and one of agitators, and pair of gear wheels on shaft in engagement with each other.

MACHINE FOR SEPARATING GOLD FROM SAND.—No. 785,819; C. O. Michaelsen, Salt Lake City, Utah.

Combination with vertical shell, built of any suitable material, with cap, and concave bottom; of rotatably movable and vertically adjustable worm cylinder, provided with two concavo-convex screw blades, firmly attached on outside of cylinder and starting from opposite sides of cylinder; cylinder being provided with ingress ports in its wall, and fun-

nel firmly attached to and forming bottom of worm cylinder, to which funnel are firmly secured at varying distances agitating arms of suitable length, and bent to correspond with concave bottom of shell, and curved in direction of motion of screw blades.

ORE PULVERIZING APPARATUS.—No. 786,088; E. H. Benjamin, Oakland, Cal.

In apparatus for described purpose, combination with shell or casing, of central guide pillar within shell or casing, oil well in lower end of pillar, adjustable plug working through bottom of pillar, central drive shaft working within pillar, universal ball bearing joint between lower end of drive shaft and adjustable plug, thimble fitted within oil well, convex bearing sleeve secured to drive shaft to work against thimble, spring held bearing interposed between upper portion of drive shaft and central pillar, means for exerting lateral spring pressure tension on floating bearing, and devices carried by drive shaft for creating upward air draft through bearing during rotation of shaft.

PROCESS OF REDUCING ORES.—No. 786,051; D. R. Robertson, Leadville, Colo.

Process for reducing ore, which consists in subjecting finely divided material in presence of water to action of sodium salt and potassium salt, heating and agitating mixture, adding salts of iron and acid and again agitating mixture, allowing mixture to rest, and removing separated values.

PICK.—No. 786,207; W. F. Gillooly, Coalton, W. Va.

Head for picks comprising body portion having socket therein for reception of handle and including laterally extending arms, arms having sockets in ends and having recesses therein communicating with sockets, points having stems engaged in sockets and extending into recesses, stems having upwardly extending lugs at free ends, latches removably disposed in recesses and having notches therein in which lugs are engaged to prevent disengagement of points, arms having depressions therein communicating with recesses, springs disposed in depressions and extending over recesses and lying in engagement with latches to hold latter yieldably in engagement with stems, and screws passed through springs and engaged in arms, screws being adapted for operation to permit of lateral movement of the springs to disengage them from latches.

### The Living Witness of the Desert's Tragedy.

In time to come, when new Nevada has reached a stage of development and repose, we can imagine her, when thinking of the loved ones she would honor or whose deeds she would commemorate, saying:

I dreamed last night of a dome of beaten gold  
To be a counter-glory to the Sun;  
There shall the eagle blindly dash himself,  
There the first beam shall strike, and there the moon  
Shall aim all night, her argent archery;  
And it shall be the tryst of sundered stars,  
The baunt of dead and dreaming Solomon;  
Shall send a light upon the lost in hell,  
And flashings upon faces without hope—  
And I will think in gold and dream in silver,  
Imagine in marble and in bronze conceive.

Within the limits of the shadow of such a dome, on a pedestal of silver, an eternal place has been earned by our four-footed friend whose picture heads the article and whose merit and worth have been belied or belittled by the poet who said, "A fellow feeling makes us wondrous kind," by the philosopher who said, "Spirit that lurks each form within, beckons to spirit of its kin," and by the general indifference to the important part he has played in the development of Nevada. With the exception of the Comstock, there is no mining camp in the State that does not owe its discovery, directly or indirectly, to the so-called vagaries of our friend, but in reality to his courage, patience and ability to suffer the tortures of hunger and thirst that drive men mad.

In palatial homes in Eastern cities fair women are decorated with wondrous jewels whose marvelous beauty mocks the sunlight. The palace, the jewels, even the women, would not be so assembled but for the part played by the burro in the discovery of Tonopah.

Other animals have been, and still are, worshipped for services to man less conspicuous than the carrier of a Savior, or the only possible companion of the dauntless prospector of Nevada's deserts. It may be that to acquaint the world with the merits that have been so long hid by time and fate is no small part of the mission of new Nevada, herself representing in all past time Mystery. G. McM. Ross.

GREAT STRESS is laid on the output of some mines by promoters and others, and usually the output is looked upon as having greater significance than it actually possesses. It is the net, and not the gross, output that is of importance. There are some mines making large output, but at a loss; still the figures of output are used to the disadvantage of unsophisticated investors, who look to the gross production only. The operating expense of a mine is as important as the gross output; but those not actually engaged in mining often overlook this important fact.

WHERE mine cost sheets will show, for instance, that during a certain month 20,000 tons of ore was shoveled for, say, 15 cents per ton, and the following month the sheets show that the cost was 2 cents greater per ton than before, it is the duty of the managing engineer to investigate this small detail. Some men consider it a trivial matter, but 2 cents per ton in this case represents nearly \$5000 per year, and, if the manager does not make it his business to look after these small things, they may pass unnoticed.

WHERE trained mining engineers have not held the reins and personally directed the destinies of the properties under their control, little advancement has been made in the past or at the present time. In some mining districts of the world practical miners, without scientific training, have had complete charge of every department of the mining industry, and in these districts things are done to-day just as they were done 100—yes, 300 years—ago; no better and no worse.

## MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

The United States Geological Survey has taken up the matter of investigating the black sands of the various mining States of the West, with a view to ascertaining what values, if any, are contained in them. Dr. David T. Day of the Survey has been in California making arrangements with the manufacturers of the various types of concentrating machines to send their machines to Portland, Or., to be used in the trial, where careful and exhaustive tests will be made on the black sands from many localities. The dredgers of California produce a large amount of this heavy concentrate, and several carloads of sand will be shipped from Oroville, Folsom and other districts in California to the Portland Exposition for test. It is the desire to test the sands for the rare metals, as well as platinum. Among the minerals it is hoped to discover in paying quantities are gold, monazite, zircon, etc. The concentrating machines will be employed in a competitive test, it being the purpose of the Survey to determine what may be accomplished with each machine without making unfair comparisons. For the purpose of this important investigation Congress has appropriated \$25,000. Sands from other States, as well as from California, are to be collected and tested at this plant.

During the St. Louis Exposition elaborate tests were made of the coals produced in the United States, \$70,000 having been appropriated for this purpose. The results of these fuel tests proved of such importance that an additional appropriation of \$202,000 has been made by Congress to continue this investigation, and W. E. Parker of the United States Geological Survey is now in San Francisco, Cal., with a view to making arrangements to have considerable quantities of the coals produced in the Pacific coast States shipped to St. Louis, Mo., for the purpose of test by various methods, including briquetting, which some of these coals require, owing to their soft and friable nature.

### ALASKA.

F. Hammond has fifty men at work in the Sheep Creek mines, 4 miles southeast of Juneau. The mill has been started.

T. J. Sweeney of the Grindall M. & S. Co. is at the company's holdings on Prince of Wales island, to renew development work.—The 5-stamp mill at the Goldstream mine on Gravina Island, 3 miles south of Ketchikan, has been started up by Miller, Irving and Brice for a test run.—The work at the Sultana property at the head of Hetta Inlet, in the southwestern part of Prince of Wales island, is in charge of C. E. Buttrick. The ore is low grade, carrying gold, copper, silver and nickel.

### ARIZONA.

(Special Correspondence).—Fifteen-cent copper has spurred the country's copper producing mines on to greater production. In Arizona all the large producers are preparing for an increase. The Phelps-Dodge smelters at Douglas are now turning out 8,000,000 pounds per month, and are increasing their capacity to 10,000,000 pounds per month this summer. The Calumet & Arizona and other Bonanza Circle properties at Bisbee are preparing for a large output. The five Circle properties hope to be turning out 10,000,000 pounds of copper per month within two years. The Old Dominion is preparing for an output of at least 30,000,000 pounds per annum, and within two years may increase this to 40,000,000 pounds—and by that time the Arizona Commercial Copper Co., which is connecting up immense ore bodies at Globe, adjoining the Old Dominion, expects to be a factor. If these companies increase this production as they plan to do, Arizona should lead in copper production by 1907.

Bisbee, April 4.

#### Gila County.

(Special Correspondence).—It is hoped that the new plant of the Old Dominion Co. at Globe will be running by June 1. The new plant would have been completed by May 1 had it not been for the washouts. The concentrating mill is about finished. It has a minimum capacity of 250 tons per day, but it can be increased to 1000 tons. Three furnaces in the smelter are in operation and a fourth furnace will probably be added. Self-weighing hoppers have been put at the ore and coke bins, and automatic feeders at the furnaces. These automatic appliances will reduce costs two-thirds. The Old Dominion should produce 30,000,000 pounds of copper per annum from the operation of three furnaces.—It is expected that by April 10 repairs will be completed on the 10-stamp mill of the Lost Gulch mine, owned by E. F. Kellner of Globe. The recent heavy rains have caused about \$1000 damage to the workings.

Globe, April 3.

E. F. Eisenhour, superintendent of the Rye C. Co.'s property, in the Mazatzal range,  $\frac{1}{2}$  miles west of Rye, is driving a tunnel to cut the ledge at a depth of 700 feet. The tunnel is in 200 feet.—The shaft on the Whelan and Sidnor & Stearns property, at the head of Pinto creek, near Globe, is to be continued to the 350-foot level.

#### Maricopa County.

(Special Correspondence).—The Oriental Copper Co. will start work on their property in the Cave Creek district. Heavy rains have delayed work on all properties at least two months.—R. E. Humpbreds of Morristown has sold claims near that place to Eastern parties, who will commence work within the next two weeks.—The mill at the Relief mine has resumed work, as a supply of fuel has been obtained since the heavy rains, and there is now but little mud on the desert roads.—S. W. Haines, from the White Tank mountains, reports the work at the Gila Gold Lode as progressing well.—The Lime Creek Copper Co. have sold their property on

Lime creek to Kentucky parties, who will erect a smelter somewhere in the Cave Creek country.

Phoenix, April 3.

(Special Correspondence).—J. V. Creath has found good ore near Frog Tanks on the Agua Fria.—Veltz & Son intend to put in a small mill on their gold property in the White Tank mountains, north of Buckeye.—L. R. Legier, who has been doing some work on a lead property northwest of Phoenix, reports the find of considerable carbonate ores.—C. Francis, T. Trook and S. Rogers of Morristown are working copper properties.—T. J. Sparks has put in a hoist on a gold and copper property east of Morristown.

Phoenix, April 5.

#### Mohave County.

Superintendent O. F. Kuencer of the German-American M. Co., at Acme, expects that within sixty days the property will be producing bullion.—L. D. Godshall has returned to Kingman from Needles and Los Angeles, Cal., where he negotiated for the purchase of the Needles smelter and the holdings of the Fletcher M. Co. The smelter will be overhauled and its capacity increased. A roaster will also be put in and the smelter will be blown in. Contracts are to be let on the Twins mine to open it.—T. P. Lamb has a bond on the New Jersey mine at Cbloride, and has started work.

The association of mine owners of the San Francisco mining district was formed "for the purpose of fostering, protecting and developing the mining industry in the district." It will endeavor to have a standard gauge railroad built in the district, and to procure pipe lines for water and for oil for the delivery of fuel and water direct to the mines. A secretary is to be elected by the association, to whom all persons desiring employment must apply. If the secretary finds the applicant of good character and well qualified to fill the position asked for, a card will be issued to him, which will enable him to secure employment when there is a vacancy reported by any member of the association. This card will be taken up by the foreman or superintendent when the holder is employed, and returned to the secretary of the association. When a man changes employers he must secure a new card. There is no expense attached to securing one of the above cards. The card system will become effective April 15, 1905, and applies to those now employed. The following scale of wages and regulations have been adopted by the association:

	Per Day.
Sinking wet shafts with machine drills.....	\$4 00
All other mining with machine drills.....	3 50
Mining in wet shafts by hand drills.....	3 50
All other mining by hand drills.....	3 00
Skilled blacksmiths.....	4 00
Tool sharpeners.....	3 50
Hoist engineers, 12-hour shifts.....	4 00
Hoist engineers, 8-hour shifts.....	3 50
Timber men.....	3 50
All laborers, muckers and trammers.....	2 50

All underground work to consist of eight hours actual labor, the men to be lowered and hoisted on their own time; nine hours to constitute a day's labor on the surface.

The above scale will govern all contracts. It was signed by the Gold Roads M. & E. Co., B. Richards, Blue Ridge G. M. Co., Victor & Virgin M. Co., Navy M. & M. Co., German-American M. Co., Gold Star M. Co., J. M. Day M. Co., Gold Giant G. M. Co., Swiss-American M. Co.

#### Pima County.

(Special Correspondence).—D. S. Rose of Milwaukee, president of the Twin Buttes M. Co., has proposed to Tucson to build a custom smelter to handle the output of the Twin Buttes property and others adjacent to Tucson. It is estimated that the Twin Buttes property could furnish 100 tons a day to such a plant.

Tucson, April 3.

It is stated that the directors of the Tip Top M. Co. in Santa Rita district intend to build a railroad 18 miles from the mines to Vail's station. A steam dredger is being put on the Ensenberg placers near Greaterville.

#### Yavapai County.

(Special Correspondence).—After remaining idle for several years, the Storm Cloud mine, which adjoins the Senator and Cash, near Prescott, is being unwatered preparatory to being examined.

The Hector group, in the Hassayampa district, near Harrishburg, is showing good ore under the work of Marsh & Martin.—Good strikes have been made at Camp Columbia on the Bear claims, and they propose to sink 100 feet, then drift and crosscut.—Employment of non-union men at Jerome is threatening a strike in the works of the United Verde Copper Co. Recently thirty-three men in the shops walked out because the foreman, M. J. Foley, was discharged and a non-union man from Pueblo put in his place. The men refused to work under the new foreman and men were at once brought from Pueblo to take their places. It is hard to tell how widespread sympathetic strikes may become among the other workmen at the United Verde, but several union machinists have left their work because of the boilermakers' dispute. Senator W. A. Clark, owner of the United Verde, is expected in Jerome soon and will doubtless find means to avert a general walkout.

Prescott, April 4.

As a result of an explosion in the United Verde mine, at Jerome, five men were killed and seven injured on April 2. The accident happened as the shifts were being changed, and all the men except twelve had been raised to the surface. They were waiting at the station on the 300-foot level to be hoisted from the mine when the disaster occurred. For six years the sulphur in the ore in various parts of the mine has been on fire, but confined to small areas by cement bulkheads that were constructed three years ago. It was believed until this morning that those had solved a serious problem. On account of recent heavy rain, the surface water flowed down upon the burning area, causing the steam thus generated to blow out the bulkheads. That part of the mine in which the accident took place has caved all the way to the surface. The twelve miners who were waiting for the cage on the 300-foot level were suffocated by smoke and steam. It is feared that the fire will spread to the other parts of the mine and cause millions of dol-

lars' damage. Unless checked, it will affect the ground on which stand the immense smelter and power house. The dead are T. W. Crofut, E. R. Ruffin, P. D. Seder, A. J. Halladam and J. M. Roe. The injured are N. Nevonich, B. Garcia, J. Koscie, J. P. Roe, B. Caropa, J. Wilovich and M. Sullivan.

It is reported that the mill at Mt. Union, near Prescott, on the properties of the Mt. Union Con. M. Co., will start April 10th. The starting up of this mill has been delayed by storms of the past three months.—G. W. Middleton will start work on the properties of the Metals M. Co., near Walker.

G. W. Hull, manager of the Cleopatra C. Co., near Big Bug, is reported as having said that within six months he would have a 100-ton smelter reducing ores from the Cleopatra mine. It is to be placed east of the mouth of the Dillon tunnel and below the road leading to that tunnel from Jerome.

## CALIFORNIA.

### Amador County.

It is reported that S. K. Thornton of Plymouth will reopen the Elliott mine at Oleta and put up a 10-stamp mill on the McKinley mine.—A rock breaker and air compressor have been put in the Keystone mine at Amador.

### Del Norte County.

The Klamath River Dredge M. & D. Co. has been formed by J. B. Dougherty and B. O. Tupper to dredge 2100 acres, from the mouth of the Klamath river 22 miles inland.

### El Dorado County.

The Granite mine, near Smith's Flat, has been sold to W. F. Almy of Boston, Mass.

It is reported that the Rosecrans Co. will resume work on their mine, near Garden Valley.—The new mill at the Live Oak mine on Reservoir hill, near Placerville, has been completed by Muller & Cardner. They have encountered some good gravel in their 500-foot tunnel. J. O'Brien of Plymouth is superintendent. It is thought Portland people will put up a mill on the property.—A London syndicate has leased the gravel properties of the E. D. W. and D. G. M. Co. of Placerville and, as the El Dorado Gravel Mining Syndicate, will begin operations at once. The Excelsior, south of Placerville, will be opened up first. A. B. Gould has charge.

### Inyo County.

Work has been stopped on M. Junghandel locations, near Big Pine, until a force pump can be put in to handle the water. The incline is down 50 feet.

### Mono County.

The small quartz mill which Davidson & Lockwood have been building on Missouri Flat, near Bridgeport, has been completed and will be run by water power from the Strosnide ditch.

### Nevada County.

The Home mine at Nevada City has started work in every portion of the mine with the exception of the disputed property. Judge Seawell of the Superior Court of San Francisco has accepted a bond of \$10,000 furnished by the Home Co., which releases the attachment on all the personal property except some broken ore in the mine, which has not yet been hoisted.

Superintendent Klewes will resume work at the Ironclad mine, near Rough and Ready. He will put in a complete electric pumping and hoisting system to replace the steam power, which was in use until the mine filled with water and shut down last winter.—Superintendent Dunlap reports a rich strike at the Lecompton mine in the Willow Valley district, near Nevada City.

### Placer County.

It is reported that the Black Canyon quartz mine, near Indian Springs, will start up May 1.—The Red Point mine, near Damascus, is being worked on a small scale, six men working there on a lease.—The Salvation mine, at Sailor Canyon, has stopped work.

### Plumas County.

The Red Slide mine, near Eclipse, is owned by Geo. Sanborn, who is driving a hedrock tunnel to strike the gravel channel.

### Sacramento County.

The El Dorado Gold Dredging Co.'s dredger, near Folsom, is completed and will be in operation within two weeks.

### San Diego County.

The bondholders of the California King Gold Mines Co., whose property is situated in Picacho basin near the Colorado river, about 30 miles north of Yuma, threaten to foreclose unless the accumulated and overdue interest is paid promptly. It had been expected to raise upwards of \$40,000 from sale of bonds and by other means with which to carry on the more extensive development of this large property. The management of this property has from the start had many difficulties to overcome. It is situated in the Colorado desert, and the only favorable feature of its location is the proximity of the Colorado river, which affords abundant water supply, though every ounce used has to be pumped. B. Moody, formerly chief engineer of the Homestake at Lead, S. D., took the management of the property in the summer of 1904, and after making some changes in equipment succeeded in getting the most satisfactory run ever made at the property, producing, it is reported, \$64,000 in four months. On this showing the directors have hoped to float more bonds to secure funds to clear the indebtedness, and place the mines on paying footing. While no definite plan has yet been adopted as to how the properties will be sold, in the event of foreclosure proceedings becoming necessary, it is understood that the bondholders will apply to sell the property to indemnify themselves, when a new company will be organized. Those holdings bonds of the present issue will secure an interest of some kind in the new company, while all the stockholders who have no bonds will not be recognized in the new organization.

### Shasta County.

D. B. Hunt of Redding and J. Sallee of San Francisco have struck high-grade ore on the Reid mine in Old Diggings district.—Work on the new 4-stamp mill being built on the John Larkin mine, in the Centerville

district, is nearly completed.—E. P. Conner and J. R. Conner have sold the Montezuma mines, near Shasta, to the Gold King M. Co. C. Johnson of Los Angeles is president and R. K. Morris secretary of the Gold King M. Co.

### Sierra County.

At the Mt. Lion mine, near Pike City, a rich strike has been made by W. H. Wayman and F. G. Low.

### Siskiyou County.

The steam machinery of the dredger in Yreka creek, at Hawkinsville, has been removed and the electric power machinery is being put in. The company is working Yreka creek from Shasta river to Yreka.—The rain of the past few weeks has enabled the hydraulic and placer claim owners to start work again.—G. W. Grayson of San Francisco, owner of the Mono quartz mine on Humbug, is making arrangements to put up a 10-stamp mill during the summer.

### Tehama County.

(Special Correspondence).—The Bazler Copper Co., operating mines 30 miles west of Red Bluff, is working eight men on development work. The vein is cut by a crosscut tunnel nearly 800 feet in length, developing from 12 to 40 feet of copper bearing ore, carrying also gold and silver values. A carload shipment was made recently to the smelter. It is expected to ship 150 tons weekly after May 1. The haul from the mine to the railway costs from \$3 to \$5, according to the state of the roads and weather. The company is considering the placing of traction engines between the mines and railroad. This is the only operating mine in Tehama county.

Red Bluff, April 4.

### Tuolumne County.

D. L. Oneto has sold to H. S. Hale one-half of the Gold Flake quartz mine and millsite near the mouth of Mormon creek, near Tuttle town.—A. M. Divoll has sold to L. R. Fulcher a one-sixteenth interest in the Frisby Annex quartz mine, near Sonora. M. Harmon previously deeded to Divoll a half interest in said mine.—The owners of the Bell mine, near Tuttle town, have taken over the Bell mine from the El Rico M. Co., who had it under a bond.—R. T. Whitto has deeded to E. R. Bolton of Jacksonville the Gladstone quartz mine.

### Yuba County.

The Hammon dredge mining interests along the Yuba river have been consolidated and reorganized under the name of the Yuba Consolidated Goldfields. The capital stock is \$12,500,000. The principal place of business is Portland, Me. E. F. Sweetzer is president and L. L. Hight secretary.

The 20-stamp mill formerly operated at the Browns Valley mine has been sold to the North Star M. Co. of Grass Valley.

The Marysville Gold Dredging Co. will commence building two mining dredgers just as soon as the water in the Yuba river is low enough to permit the pits to be evacuated. The dredgers will be of the same type as those in use at the Yuba Con. Gold Fields adjoining the Marysville Gold Dredging Co.'s holdings on the east. W. P. Hammon of the Gold Fields property will be the managing director of the Marysville Co. and R. E. Cranston will be superintendent. The first work to be done by the dredgers will be that of building the two training walls contemplated in the Government plans for correcting the Yuba river and giving it a straighter and better defined channel from Daguerre Point to Marysville. This work will consist of two walls aggregating several thousand feet in length, and enclosing between them a canal which will constitute the new channel of the river. As the walls on each side will be 30 feet high, the water will be confined in the channel and will scour the bottom, sluicing it out and lowering the bed of the river with every freshet.

A. F. Eaton of San Jose has bonded for Chicago, Ill., capitalists 3000 acres of land 6 miles east of Marysville, on the south side of the Yuba river, for dredge-mining purposes, and will put three drills at work.

## COLORADO.

### Clear Creek County.

Manager G. W. Teagarden of the St. Paul M. Co. at Georgetown is completing arrangements for machinery for the new power plant and for machine drills. The company has started a tunnel to open up the veins of Green Lake mountain.—J. G. Roberts has sold to J. Morton of Georgetown a one-fourth interest in the Blue Ridge millsite and Capital ditch, giving Roberts the ownership of the entire property. A sampling works plant has been put in at the mill.—The Capital mill is treating twenty-four tons of ore daily. It is thought that an electric motor will be put in to take the place of horses on the tramway.—The two deep workings of the Mineral Chief vein are being pushed ahead by Manager W. C. Hood. The lower drift from the Moline tunnel is in 185 feet from the tunnel and 639 feet from the portal of the tunnel. This drift will open up the ore shoot 500 feet deeper than the upper workings on the Mineral Chief. The level from the Spartan drift is in 143 feet from the crossing of the veins and 283 feet from the surface.

### Chaffee County.

The Latchaw G. M. Co., on Mount Princeton, near Hortense, has its tunnel in nearly 3000 feet. An aerial tram 7000 feet long is to be built to connect the tunnel with the "transfer," 1½ mile below where the power now is, compressed air being conducted to the mine by pipe line. The company will put in an electric power plant on Chalk creek at the Cascades, the tunnel leading the water through the mountain already having been completed. This will furnish the power needed for the mills they will build. C. I. N. Sharp is manager.—The Stratton-Massachusetts G. M. Co., 5 miles east of Buena Vista, under the management of N. A. Stratton, has a portion of the material for the new mill on the ground.—In the Four-mile district, 2 miles from Buena Vista, the Centennial is being put in shape by F. Denman of Colorado Springs. It is being unwatered and retimbered.—The Sunshine mine, near the Centennial, has begun work.

### Hinsdale County.

Snowslides near Lake City have caused temporary stopping of work at the Big Casino and at the Easy Creek, at the head of Cooper creek.—A. G. Wood and associates, who are leasing on the Golden Fleece, have ore ready to ship. Milling ore will be handled as soon as the weather settles.—The Golden Fleece (eighteen claims) are on Hotchkiss mountain, 4 miles south of Lake City, in the Lake district.—It is reported that W. S. Whinnery will reopen the St. Jacobs mine at Carson.

### Lake County.

(Special Correspondence).—During March the Leadville mines shipped 78,000 tons. The Western M. Co. shipped 15,000 tons, of which 7000 tons came from the second contact ore bodies in the Coronado. The Iron Silver M. Co. shipped 12,000 tons from the Moyer group. The output of the Western Company is expected to be increased when the three new pumps are put in at the Penrose. The Coronado pumps are now lifting 1200 gallons a minute, and the Penrose pumps 1400 gallons or 2600 gallons from these two shafts. These new pumps have a capacity of 900 gallons a minute each. When they are started, over 5000 gallons a minute will be pumped from the Downtown mines, and development, which has been hampered by the water, will be pushed.—Reports from the Mosquito district state that a new body of ore has been opened in the London mine. J. M. Kuhn is manager.

Leadville, April 3.

At the Boswell placer, near Twin Lakes, a flume will be built to connect with 600 feet of 10-inch pipe line, giving a 300-foot fall for hydraulic giants. L. Foster will have charge.

### Ouray County.

Manager Manion, of the Brooklyn mine, in the Red Mountain section, states that the working force is to be increased and shipments of ore will be resumed.

The outlook for the Revenue mine at Ouray is better than it has been for years. The force has been increased by seventy-five men, making 275 in all. It is reported that within sixty days more the force will be increased to between 400 and 500. The water, which has been giving them so much trouble, is under control, since the new, large pump has been put in.—A shipment has been made by the leasers on the Hoosier Girl, one of the Camp Bird Extension group.—W. R. Kramer has a lease and has started work on the Governor, on Stoney mountain near Ouray. A mill was put on the property last fall, and good results were obtained from it until they were compelled to shut down on account of lack of water.—Griffith & Fuller, who are leasing on the O. & N., have opened up a large body of low-grade ore on that property.

A snowslide at the Banker National tunnel, near Camp Bird, in the Mount Sneffles district, on April 1, caught six men and killed two.

### Park County.

(Special Correspondence).—The London mine at Alma is shipping 15 to 20 tons per day. J. M. Kuhn is superintendent. Development on this mine consists of 2700-foot drift on south side, about 3000 feet on north side, with 300-foot raise from south drift to connect with north side, making ventilation good. This mine is on the London fault, which can be traced for 12 miles.—Superintendent E. P. Ibsen of the Paris mine on Mt. Bross, near Alma, is working a few men and has all available room filled with ore.—The Dolly Varden on Mt. Bross, C. D. Hall superintendent, is closed on account of snow, but will be worked when the weather settles.—The Kansas mine, above Montgomery, is being worked by Clark & Eddy Bros. under lease. They have some good ore and will begin shipping as soon as the trail improves.—The Wheeler mine on the head of the South Platte, under lease to Eldridge, Kuhn & Anderson, is shipping. This ore is packed out by jacks, 11 miles.—The Old Moose mine has three men doing development work.—All these mines are at or above timber line on the Continental divide. Timber line here is about 12,000 feet above sea level.

The Snowstorm Hydraulic Co. have one churn drill at work testing the gravel on the Snowstorm claim. Surveyors are at work on the high line ditch for a better water supply on the Alma claim.—The Beaver Creek claim is not being worked at present. The Snowstorm and Alma will be working full force as soon as spring opens.—The Cincinnati P. M. Co. are not doing any work, although reports say that they will start soon.

Alma, April 1.

### San Juan County.

The boiler and engine-room and the blacksmith shop of the Iowa M. Co. in Arrastra gulch, near Silverton, were wrecked by a snowslide on April 1. The mill was covered with snow and the tailings plant destroyed.

### San Miguel County.

A dynamo and blower are being put in to give air to the Pennsylvania tunnel, which is being run to cut the Smuggler vein, under contract by the Goldfield Rex M. Co., under the supervision of A. A. Clute of Telluride. This company also has a lease on ground which they propose operating when the vein shall have been cut.

The Bohtail snowslide near the top of Ajax Peak partially destroyed the Smuggler Union tramway. The 74-foot tower on the bank of Marshall creek was knocked from its foundations. The men employed by King & Lindsey and the Telluride Leasing Co. on the Smuggler Union mines have been temporarily discharged.

The Invincible G. & S. M. Co., of which J. A. Ross of Denver is general manager, will work on claims in Navajo basin, Mount Wilson district, as soon as trails leading to the property are passable. The main tunnel is to be driven 30 feet, to intersect the vein of the Zero.—The recent snowstorms have interfered with the plans of some of the mine operators relative to increasing their working forces, and the increase expected about the 1st of April will not occur until about the 15th.—Wagner Bros. will put additional men to work on their leases on the '76 mine, one of the Smuggler-Union properties, and the Smuggler, Union and Sheridan dumps. Operations on the Keystone placer have been set back, and Superintendent Harris has not been increasing the force as expected.

## Sammit County.

The North American Mines Co., operating at Curbin, in the Ten Mile district, has laid out a new tunnel location to cut all lodes at the greatest possible depth, leaving sufficient elevation for a mill close to the railroad. —At Frisco the Copper Queen mine, now being operated by the Mary Verna M. Co. of Memphis, Tenn., is being developed by a tunnel, which is in 320 feet. —The Washington-Joliet Company on Nigger hill, near Breckenridge, is employing thirty men, blocking out ore to have an ore reserve when the mill, now being repaired, is ready to resume operations.

The Gold Dust Mines Co. has been formed by M. W. Hoyle, E. J. Hoyle and R. R. Kirk at Breckenridge.

## Teller County.

The production for March in the Cripple Creek district was as follows:

Name of Plant.	Tons.	Av. Value.	Total.
U. S. Reduction & Refining Co. ....	25,000	\$30.00	\$ 750,000
Smelters .....	2,500	60.00	570,000
Portland .....	7,800	30.00	234,000
Economic .....	3,000	35.00	105,000
Dorcas .....	3,500	32.00	112,000
Wild Horse .....	2,400	6.00	12,000
Anaconda .....	1,400	7.20	10,080
Other cyanide plants .....	1,000	6.00	6,000
Totals .....	53,800	\$35.90	\$1,829,080

Shipping has been resumed from the Gold Sovereign mine at Cripple Creek by Manager W. F. Rock. The new ore house can handle 100 tons a day. An east and west vein has been opened in the bottom level at a depth of 700 feet. Ore is being broken in the main shoot, 200 feet south of the shaft, on the 700-foot level, where the Gold Temple Co., former lessees, left off. The bottom of the shaft is 40 feet below the 700-foot level. The objective is 800 feet, where a crosscut will be started to reach a possible extension of the Triby shoot.

The Geneva, on Gold Hill, Cripple Creek, has been leased by the Stratton estate to an operating firm, including F. Welland, H. D. Warmuth, J. Hull and Wm. Catlin. They are arranging for putting in a 12x12 hoist. The shaft is 600 feet deep. —At Cripple Creek the Pharmacist Co. has granted a lease on the southern end of its Bull hill property to F. M. Gilbert, who will commence work at the bottom of the shaft at a depth of 660 feet, and from this depth will drive a number of drifts to the side lines of the ground under lease. The lease calls for the sinking of the shaft another 150 feet. —Lessee Smith, operating on the Sentinel claim of the Twin Sisters Company, has stopped work because of the immense amount of surface water due to the melting of the recent heavy snowfall. When operations are resumed, drifting will be started.

Leases on the Stratton estate property have been granted to R. P. Russell, A. T. Holman, F. M. Kurie, J. M. Roach, president of the Chicago Tramway Co., A. Cornforth, R. H. Hefley, W. A. Matlock, C. Waldron, F. V. Bodfish, C. L. Lightburn, J. P. Bates, C. H. Starkweather, J. Finn, W. H. Tuttle, G. Davis, J. W. Newell, F. H. Bostwick, T. S. Rhett, W. A. Kelly, G. A. Stahn, E. M. Pollins, J. M. Wright, R. K. Hutchin, W. F. Jones, W. H. Fitch, T. Kelly, J. W. Huffaker, N. Franklin, G. Bernard, W. Bainbridge, J. F. Shafroth, J. B. Board and M. V. Andre.

An ore shoot 68 feet from side to side is being worked by Lessee Walsh on the Forest Queen mine on Ironclad hill, Cripple Creek. The operators are preparing to increase their boiler capacity, and when this is completed they will sink an additional 100 feet, which will give them a total depth of 875 feet, besides allowing them to increase their shipments. —As soon as conditions will permit, the work of installing machinery at the Empire State shaft of the Isabella Co. at Cripple Creek will be started. The machinery ordered includes a first motion hoist, good for a depth of 1500 feet, and a Norwalk air compressor. As soon as this machinery is put in place it is the intention of the operators to sink the shaft another 400 feet.

## IDAHO.

## Blaine County.

C. Johnson, superintendent of the Drake Mines Development Co., has started work at Skeleton creek, near Hailey. The company will build a mill upon its property this summer, and R. P. Chattin & Co. and the Mountain Home Co. also intend to put in mills this year. When these three mills get to their regular work, the bullion output will demonstrate the value of the district.

J. Williams, manager of the Wood River Zinc Co., says that the company will buy all argentiferous galena and zinc-lead ores offered after the mill has been working awhile.

## Idaho County.

C. W. Smith of Newsome, resident manager of the Anaconda group, near Newsome, reports that the property has been bonded to Eastern capital represented by W. L. Stevenson of Spokane. The property will be incorporated as the Graham M. & M. Co. A mill will be shipped in as soon as conditions of the roads will permit. —J. A. McEachron, manager of the Elk Gold Co., will begin work on the Albertas group, near Elk City.

## Kootenai County.

The act of the Idaho Legislature dividing Kootenai county into Lewis and Clark counties has been declared unconstitutional.

## Shoshone County.

J. Morrow and W. S. Wilkinson have been developing the Wild Rose, near Pierce City, and state that they have tapped a good vein of rich ore by a new drift into the shaft and have also made a new discovery a short distance from the Wild Rose lead. The Wild Rose mill will be started about July 1. —The Laclede M. Co. will put in an air compressor on the property, near Wallace, as soon as the weather conditions will permit. The company is running a 700-foot tunnel which will give depth 200 feet below the upper workings. —The prospecting work on the California and Black Cloud properties and the Pan Handle on Nine-Mile creek, 2½ miles from Wallace, has proven satisfactory, and development work has been started by the Heins Silver & Lead M. Co. under superintendence of C. H. Maiden. J. H. McClarren of Pittsburg, Pa., a stockholder, has been at the mine. —J. McLaren has started a lower tunnel to develop the

Ruth vein, near Wallace. O. Wallace of Spokane is manager of the Ruth M. Co. —J. L. Safford and G. Safford of Spokane are sluicing in Milo creek, near Wardnor. —Wardner reports say that the long tunnel on the New Jersey property, near Big creek, is in 500 feet. Bell Bros. of Big creek have the contract for 1000 feet of tunnel. —Work has again been started on the Western Star property on Big creek. The tunnel is in 900 feet and has some good looking ore in the face.

The Snowstorm copper mine, near Mullan, is building a leaching plant for treatment of its second-class ores. The upper level is under lease to J. H. Howard & Co. At present 100 tons are being shipped daily to the smelters from the upper works. A large body of good shipping ore was opened up in the 1000-foot level last fall, but to date no shipments have been made from this level. An aerial tram brings the ore down from the mine 1½ miles. The property is a fine tunnel proposition, affording large stoping backs. —The Iron Spar Copper M. Co., southeast of the Snowstorm, have opened good values on their copper vein. J. J. Curran is president of the company. —It is reported that the Custer mine, on Custer peak, between Wallace and Murray, will resume shipping.

## MICHIGAN.

(Special Correspondence). —The Quincy M. Co.'s smelter at Hancock is working full capacity. The new furnace is giving satisfaction. The Quincy is also hauling the production of the Franklin, Adventure, Mass and Centennial properties. —At the plant of the Michigan Smelting Co., owned by the Stanton-Paine Mines, the difficulties which retarded operations since the furnaces were blown in have been eliminated. The production of the Copper Range Con. mines—Baltic, Trimountain and Champion—is being treated, and upon the expiration of the contracts of the Wolverine, Mohawk and Atlantic companies with the Calumet & Hecla corporation the output from those properties will be handled. The present capacity is 72,000,000 pounds per annum, but the management intends additions which will increase it. The Calumet & Hecla M. Co.'s smelter at South Lake Linden has been treating the product of some of the Stanton mines. —Owing to the withdrawal of the mineral shipments from the Copper Range Con. mines, which were necessarily shipped there during the period of repairs to the Michigan smelter, the Hancock plant of the Lake Superior Smelting Co. has been closed down. —Work at the Franklin mine is still suspended, owing to the strike of the trammers. The management says it is not prepared to meet the higher wage scale demanded and would rather keep the mine idle. —A permanent steel shaft and rock house at No. 2 shaft of the Baltic mine will be built during the coming summer. The Baltic mine has four permanent shafts—Nos. 2, 3, 4 and 5. The three latter are equipped with steel rock and shaft houses, but the new structure at No. 2 will be provided with larger rock bins. Permanent hoisting engines are in service at No. 3 and No. 4, and at No. 2 an engine house has been completed. A double conical drum, high duty hoist for permanent service is ready to be put in. —Work on the Osceola branch of the Calumet & Hecla mine is going ahead steadily at No. 13 shaft, the southernmost opening on that bed, where twenty drills are in service. This shaft is nearly 1500 feet deep. —At the Centennial mine No. 1 shaft is sinking below the twenty-fifth level at a depth of 2800 feet. No. 2 shaft should be completed within six months, solving the ventilation problem. —The March production of the district has been curtailed by labor troubles, which, while not serious at any mine, caused a few days' suspension at a number of properties and reduced the aggregate production.

Calumet, April 3.

## MONTANA.

## Fergus County.

J. A. Drake of New York is expected at Kendall to make plans for development at the North Moccasin property, at Kendall. —President G. M. Nelson of the Chicago-Montana G. M. Co. has made an offer to miners and others who have claims against the company to pay in full and resume operations if they will stay all proceedings for forty days. Within that time a meeting of the stockholders will be held in Chicago.

## Granite County.

Chas. Boyd and Alex. Boyd and Aug. Lindstadt have sold their mine in the Red Lion district to G. H. Savage, of the Milwaukee Gold Extraction Co., for \$9000.

At the Albion mine in Deer Lodge basin, near Princeton, a strike has been made in the face of the main tunnel, which is in 900 feet. F. C. Arnold of Butte is president and H. Hinkle of Butte is secretary. —T. H. Murphy and Charles Bagley of Phillipsburg have a lease and bond on the Schiller & Steinhauser property, near Princeton, and have commenced work.

## Lewis and Clarke County.

The Brooklyn Bridge M. Co., south of Helena, proposes to begin work on a new double compartment shaft 500 feet deep.

The Carbonate Chief, in Warm Springs district, near Helena, is being worked from a tunnel through the Bell mine, and shipments are being made via Clancy to the East Helena smelter. J. Stinbrenner of Helena is the principal owner. —The Howard mine in Grizzly gulch, 2½ miles from Helena, is being worked by Mr. Essler. —The Comet, near Wickes, is being worked under a lease by Gulio, who is shipping thirty tons a day to the East Helena smelter. —The South Bend M. Co. is working its mines on Ten Mile, 4 miles from Rimini. —The dredger which has been built for operation in the Missouri river at French bar, under the supervision of Mr. Reynolds, has made a trial run. —M. Manuel has put in a hoist at the Minnesota, near Wickes, and will sink another 150 feet. —The Edward F. Co., operating near Hassell, will put in a 20-stamp mill and cyanide plant.

## Madison County.

The Green-Campbell M. Co., operating the Green-Campbell and other mines near Silver Star, is considering plans for a stamp mill.

## Silver Bow County.

(Special Correspondence). —The old Colorado S. & M. Co., one of the Amalgamated assets, has gone out of existence, as the Amalgamated Co. has formed the Trenton M. & D. Co. under the laws of New Jersey, to succeed the Colorado corporation. —Mining claims about Butte, the old smelter, and all other assets have been transferred to the new company. —The Amalgamated Copper Co.'s option on the Speculator group has lapsed and it is said that a Duluth company has taken it. The Speculator owns the Speculator, Jesso and the Edith May.

Butte, April 3.

It is reported that high-grade ore has been discovered in the Raven mine in Centerville, 5 miles from Butte, at 700-foot level. The president of the company is C. E. Morris of Pony, Montana. J. Bergin is manager.

## NEVADA.

## Churchill County.

Geo. Abrogast is developing a property near Bernice. Esmeralda County.

(Special Correspondence). —The Mohawk Alpine Co. at Silver Peak have closed down their mill until better water can be piped to the mill from near the Blair mill. —The Combination mill at Goldfield is waiting for water, which is to be pumped 10 miles from an alkali spring through a 3-inch pipe. —The Goldfield Reduction works are almost ready to start their 10-stamp mill. —A new strike of silver-lead ore is reported from Palmetto, 20 miles from Lida.

Goldfield, April 3.

The property of the Cash Goldfield M. Co. is being developed under the management of R. B. Todd of Goldfield. —The Gold Button M. Co. has started another shaft in the Black Cop ground. It will be sunk 40 feet, when crosscutting will begin. —The Kawich-Bullfrog Mines Co. is working in the Kawich district under the superintendence of W. Pike and in Bullfrog under direction of L. C. Beckwith.

The following information regarding Nevada's latest mining camps has been compiled from local papers: Goldfield is 28 miles south of Tonopah; 16 miles south of Goldfield is Tank Springs; 29 miles south is Summerville, the new strike, which is 3 miles west of Thorp's mills; 28 miles south from Summerville is Muddy Spring; 8 miles south from Muddy Spring is Old Bullfrog or Amagosa (now deserted), where the original Bullfrog mine is located. Rhyolite is 4 miles east from the Original Bullfrog mine, a town of 400 population, the center of the Bullfrog district, now about six months old. Bullfrog is ½ mile south. From Rhyolite to Beatty is 4 miles northeast, passing the Montgomery-Edwards mine. South from Beatty 4 miles is Gold Center. —A telegraph and telephone connects Goldfield with the outside world. An electric plant furnishes light for stores and residences. In its first year Goldfield shipped \$3,038,000 worth of ore of average value of \$47.60 per ton. In the same time \$1,208,000 worth of milling ore was placed on the dumps. There are eighteen mines in shipping ore—\$100 per ton or better. Deepest shaft, 315 feet. Area covered by mines producing ore, 12 square miles. Six mills for treating lower grade ores now in process of construction. It is reached by Southern Pacific railroad to Reno, Nevada, and over narrow-gauge railways from Reno to Tonopah, and thence by stage or automobile direct to Goldfield. Railroad fare from Reno to Tonopah, \$17.50. Stage fare from Tonopah to Goldfield (about 25 miles across the desert), \$4. Automobile fare from Tonopah to Goldfield (about 26 miles), \$6. Baggage allowed each passenger by railroad companies to Tonopah, 150 pounds. Baggage allowed each passenger by automobile company, Tonopah to Goldfield, twenty pounds. Baggage allowed each passenger by stage owners, Tonopah to Goldfield, fifty pounds. Time consumed by railroad trip from Reno to Tonopah, 18 hours. Time consumed by automobile ride from Tonopah to Goldfield, two hours. Time consumed by stage ride from Tonopah to Goldfield, five hours. Express (Wells, Fargo & Co.) rate from San Francisco to Goldfield, \$9 per 100 pounds; from Reno, \$7.50. Excess baggage rate, Tonopah to Goldfield, per 100 pounds, \$2. Hauling by mule team, general merchandise, lumber, etc., Tonopah to Goldfield, per ton, \$30. Prices current in Goldfield: Hay, per ton, \$55; lumber, 7 cents per foot; kindling wood, \$18 per cord; kerosene oil, 60 cents per gallon. No coal is used except in blacksmith's forges. Camp stools, 75 cents; kitchen chairs, \$1.50; small kitchen tables, \$5; small kitchen stoves, \$18 to \$40; table kerosene lamp, \$1; mattresses (wool waste filling), \$6; agate tea kettles, \$1.50; coffee pot, \$1. Furnished rooms in adobe houses, \$1.50 per day for one person and \$2 per day for two persons if they occupy one bed. There are half a dozen good restaurants in which prices only about 25% above city prices are in vogue. Fresh milk, 25 cents per quart; Eagle brand condensed milk, 25 cents per can; best coffee, 60 cents per pound; granulated sugar, 10 cents per pound; bread, three loaves for 25 cents; sirloin steak, 30 cents per pound. Boots blacked, 25 cents; shave, 25 cents; hair cut, 50 cents; city prices; all local and out-of-town newspapers, 10 cents; Everybody's Magazine, 20 cents; Harper's Magazine, 50 cents; Puck, 15 cents; MINING AND SCIENTIFIC PRESS, 20 cents. Miners earn from \$4 to \$4.50 per day; laborers, \$4 per day; waiters, \$4 per day and board; porters, \$4 per day; restaurant cooks, \$6 per day and board; bartenders, \$6 per day; clerks, \$4 per day; printers, \$5 and \$6 per day; stenographers and typists, \$90 to \$125 per month; painters, \$6 per day; carpenters, \$6 per day; chaffeurs, \$6 per day.

## Humboldt County.

(Special Correspondence). —Thos. Kinney has located claims on a high-grade gold and silver ledge 5 miles south of Ashdown. —The Pine Forest Gold Co. J. H. Ashdown manager, is working forty men on their No. 10 tunnel being run to cut the vein. —The Vicksburg Denio Gold Co. and the Kentucky M. & D. Co. are doing some work. —W. J. Dakin and F. M. Payne are sorting ore for shipment from their mine 15 miles south of Ashdown.

Ashdown, April 3.

## Lincoln County.

The Searchlight, in describing the Eldorado Canyon district, says that a 325-foot tunnel is being run on the Eldorado vein to meet the working shaft at the 125-foot level. C. F. Lee has charge of the work for C. H. Kelley and C. G. Austin of Seattle, Wash., who have bonded the mine.—M. E. Paddock has charge of the Eldorado property of Miller & Miller of Cripple Creek, Colo.—E. J. Roberts has a bond on the Silver Legion and Good-enough claims, in the west end of the canyon, from J. S. Sartain.—The Knob Hill G. M. Co. has twelve claims south of the Silver Legion. L. W. Walker of Los Angeles, Cal., is manager.—The Poppy and Lombard groups have been bonded by A. M. Jennings and J. M. Evans of Eldorado Canyon.—J. W. Copp and E. P. Jeanes are working the Mountain claims.—The Buster and adjoining claims are being worked by the Black Hawk M. Co., C. E. L. Gresh of Searchlight manager.—C. Clark intends to put in crushing machinery and a cyanide plant to work the Hillside, in Eldorado canyon.

At the Buck mine, near Fay, operations have been resumed, with the management drifting north and south on the ledge.—The Deer Lodge Company at Fay will put in a compressor and machine drills at an early day. The new tunnel is expected to connect with the ore bodies in the next 1200 feet. H. H. McAndrews is manager.

The Los Vegas Times says that the Wilson-Lyons Construction Co. of San Francisco are operating a deposit of sandstone 10 miles west of Las Vegas.—A. M. Jennings, president of the Southern Nevada M. Co., will sink a 500-foot shaft.—C. E. L. Gresh, manager of the Black Hawk M. Co., has found water in his well on the Buster claim and will build a 10-stamp mill as soon as the lumber can be secured at Las Vegas. There are two 85-foot shafts on the Buster, 300 feet apart, with 12 feet of ore, said to average \$20.

## NEW MEXICO.

## Otero County.

The Southwest S. & R. Co. has made plans for a 400-ton smelter to be built at Jarilla. The company owns and controls 600 acres of mining claims at Jarilla and is leasing the ground.—The Kansas City Co. has put men on the Ruby and Monte Cristo claims at Jarilla and has commenced the shipment of ore to the El Paso smelter.—The Nannie Baird, at Jarilla, is reported producing gold ore running \$300 per ton. It is owned by C. B. Eddy and C. D. Simpson.

## OREGON.

## Baker County.

The Columbia mine, near Bourne, has ceased sinking from the 700-foot level and is crosscutting and stopping from upraises. The mill is kept constantly going.—The E. & E. at Bourne is employing the largest crew in the history of the mine and the output of ore is correspondingly large.—The North Pole, below Bourne, has been worked this winter. The hauling of ore to the smelter at Sumpter has been suspended until the roads are in good condition.—The Cracker Oregon at Bourne has been driving its main tunnel on the ledge during the winter. The mill has not been operated during that time.—D. Willard, manager of the Little Cracker, is awaiting good weather before starting work where it was left off last fall. Snow is very deep at this property.

Manager F. S. Baillie of the Columbia mine at Bourne has completed the water power and compressed air plant erected on Fruit creek, a short distance below the Goldconda mine. An air pipe has been laid from this plant to the hoist at the collar of the main shaft. The Columbia has water power, applied directly, for the 20-stamp mill, but has been using steam at the hoist.—Arrangements have been completed for driving 500 feet on the lower Imperial drift at the Imperial property, Cable Cove. The additional work was arranged for following the visit of President A. H. Sibley of Detroit.

Pursuant to an injunction served on the Columbia mine management at Bourne, operations under the contract with the Taber Fraction have been suspended. The latter enjoined the Columbia from extracting ore from the Fraction under the contract pending until an accounting is made of the amount of ore formerly taken out. It is claimed that the Columbia has extracted \$50,000 worth of ore from the Fraction, for which no accounting has been given, and judgment is prayed for in that sum. The Columbia has not suspended work in its own ground.

## Crook County.

The ranch of D. W. Barnett, near Culver, on which petroleum indications were found last fall, has been bonded for \$10,000 to A. Mason and Portland men, who will push drilling. The bond provides that those holding it shall drill not less than 1000 feet inside of one year from the date of the contract.

## Grant County.

Manager J. W. Hughes of the Equity Company, operating in the Quartzburg district, states that the 5-stamp mill of this property is to be started. Most of the development during the winter has been on the Oregon claim.

## Josephine County.

The Scenic mine at Greenback has been purchased by W. H. Brevort and will be known as the Martha mine.—T. J. Mackin and A. J. Bennett have formed the Leland M. Co. to raise money to put a mill on the Golden King quartz mine, 3 miles from Greenback.—It is reported that F. Clemens will start the Yellow Horn mill, near Placer.

## Wallowa County.

The management of the Tenderfoot property, 20 miles from Joseph, is preparing for spring work. The 20-stamp mill, ordered two years ago, will be finished this season.

## SOUTH DAKOTA.

## Custer County.

F. C. N. Graydon of Custer expects his company to resume operations at the Tripoli mine, near Argyle.

## Lawrence County.

(Special Correspondence).—The Oro Hondo Co., whose shaft is near Kirk, a mile south of Lead, are consider-

ing the probable location of the Homestake ore shoot, in its dip and trend into their own property. The Homestake belt undoubtedly extends for miles, but its greatest development, and thus far its greatest value, lies between Deadwood gulch on the north and Gold Run on the south. The several great ore shoots occur along the mineralized zone known as the Homestake belt. These shoots are separated from each other, on the strike of the vein, and occupy various positions in the broad zone of mineralization occurring throughout an area about 2000 feet wide and 6000 feet long. The strike is about 30° west of north, the dip northeasterly, and the trend of the ore shoots, as far as known, is to the southward, at an angle approximately similar to the dip. The Oro Hondo property, being nearly a mile to the southward, the trend would carry the vein well to the eastward, and it seems improbable that the Oro Hondo shaft if properly located can strike the Homestake shoot at a point nearer than 4000 feet from the surface, and it may be deeper. Ore has already been developed in the shaft of the Oro Hondo property, but that it is a portion of the Homestake shoot is improbable. A crosscut to the northeastward would possibly strike ore in greater amount, but such a crosscut run from the present bottom of the Oro Hondo shaft would in all likelihood pass over the Homestake shoot if it goes this far to the southward, but in this development there is always the possibility of striking a new shoot which as yet has remained undiscovered.

Lead, March 26.

Superintendent John Croft, of the Redfern G. M. Co. of Deadwood, will sink from the 100 to the 200-foot level on the property near Redfern station, 25 miles south of Deadwood.—J. W. McClure of Des Moines, Ia., president of the Queen of the Hills G. M. Co., has straightened up the company's affairs and will complete the stamp mill in Whistler's gulch, near Deadwood.—The Imperial Mining Co. is increasing the size of its cyanide plant at Deadwood by the addition of two more cyanide tanks, with a capacity of 275 tons each. The output of the mill for last month was 3200 tons and the increased capacity will bring it up to 4500 tons per month. The capacity of the mill at the present time is 120 tons per day and the new tanks will bring the output to 150 tons daily.

It is reported that sinking will be resumed in the Big Four shaft, above Central City. No underground work has been done by this company since its shaft house burned in December, 1903. The shaft is 170 feet deep. P. T. Baird is superintendent.—The Hercules mine, above Galena, intends shipping ore to the Branch Mint mill when it is completed.—The Rex G. M. Co. of Lead is being worked under the superintendence of J. Gilroy. This company has a gasoline mining plant, the hoist having a capacity of eight tons from a depth of 1200 feet.

## Pennington County.

The Golden West Mining Co. will resume operations on its property, near Rochford, early in April, and the mill be put in operation, the weather permitting. The mine has a shaft 80 feet deep and about 500 feet of tunnel. The flume furnishing power for the mill is 2 miles in length. The ore is free milling, and the mill of Chilean type is capable of treating 100 tons in twenty-four hours.

At the Gertie tin mine at Hill City, E. C. Johnson is erecting the 15-ton mill, with the help of local men taking stock in full for their labor, says the Mining Review. The stamp mill and engine are all set. The rest of the machinery is on the ground, including a Blake rock crusher, ore feeder, amalgamating plates to save the gold in the rock, and a concentrator to save the tin. The floors are all laid and two large ore bins are nearly completed.

S. Morrow of Silver City announces that work is to be resumed by the Jenny Gulch M. & M. Co. on its quartz veins, 1 mile southeast of Silver City.—The Calumet M. & M. Co. is prospecting and working the Kelly placer bar near Silver City. H. L. Osborn is general manager.—E. P. Tuttle of Silver City and G. P. Billups of Rochford are developing the Dictatum claims, 1 mile northwest of Silver City.—It is reported that the Montezuma mill, near Rochford, will be started soon. At the mine a double track tunnel is being driven to cut the vein at a depth of 500 feet.—The Golden West M. Co., working the Benedict and Yellow Bird in the Hornblende district, 5 miles west of Rochford, is ready to supply ore to the new mill. The mill is 2700 feet from the mine and connected by an aerial tram and is operated by water power from a 7000-foot flume giving a fall of 107 feet and generating 140 H. P. C. E. Curtiss has charge.—F. Herbert, manager of the Clara Belle mine, 8 miles north of Custer City between Oreville and Sylvan Lake, intends sending ore from the 260-foot level of the shaft to Denver to determine the best methods of handling it.

After years of litigation it is reported that the Standby mine, a mile below Rochford, is about to resume operations, the trouble having been settled. The property has a 60-stamp mill which, with a little repair, can be started up. The owners claim that they can mine and mill the ores for less than \$1 per ton. The company has a shaft, one tunnel over 400 feet, besides a large amount of other underground work.

The steam hoist at the Canton mine, near Hill City, has been put in place. The company has constructed a commodious new shaft building and is excavating the ground for a 20-ton test mill. The intentions of the company are to put in a large plant with the Chilean process, the same as the Lundberg, Dorr & Wilson plant, if everything is found to work satisfactorily. The main shaft is 100 feet deep, from which 300 feet of drift has been extended along the vein. A. Anderson is at the head of the work.

J. B. Taylor, of the Black Hills Copper Co. of Rochford, says that everything has been prepared for the resumption of operations at the company's mine, the new water system having been completed. The company's annual meeting occurs on April 11th in Deadwood, when affairs will be discussed and plans laid for the season's activity.—A shaft is being sunk on the Dakota-Calumet, near Sheridan, to open up the two copper veins by drifting from the bottom of the shaft.

## UTAH.

## Juab County.

The ore shipments from the mines of Tintic for March aggregated 662 carloads, of which the Centennial Eureka mine contributed 357 carloads. The bad wagon roads connecting some of the mines with the railroads have curtailed shipments somewhat during the past month and the output for the month of April should be larger. The output for the month of March in detail was as follows: Centennial Eureka, 357 tons; Bullion Beck, 37; Gemini, 60; Eagle and Blue Bell, 36; Uncle Sam, 15; Godiva, 2; Yankee Con., 21; Carisa, 11; Grand Central, 31; Mammoth, 44; May Day, 16; Star Con., 6; South Swansea (lease), 2; Joe Bowers, 1; Ajax, 6; Lower Mammoth, 1; Swansea (lease), 2; Victoria, 6; Monterey, 2; Victor, 5; Marlow & Baxter, 1. There were also four carloads of concentrates shipped from the Uncle Sam mill during March.

## Salt Lake County.

The Columbus Con. at Alta is working eighty men, in sinking the two shafts, and breaking ore above the tunnel level, and transporting it through the long tunnel to the mill. At present fifteen teams are hauling concentrates to the smelter, but this amount is inadequate. A. O. Jacobson is superintendent.—The South Columbus at Alta is driving ahead at the rate of 3 feet per day, with their power machinery.

Manager Crowther of the Continental-Alta reported on Wednesday night the presence in several stopes of from 4 to 6 feet of good copper ore, upon which he has begun stoping, as the new buckets have been added to the tramway. The main tunnel, which has been driven 3500 feet, is now connected with all portions of the mine after eighteen months of drilling.

The Bingham Bulletin reports that the Utah Copper Co. has decided to commence the construction of a milling plant of 6000 tons capacity upon its property near Pleasant Green, 12 miles north of Bingham. The present mill at Bingham is to be enlarged at once to a capacity of 1000 tons, making a total milling capacity of 7000 tons daily. A railroad 15 miles in length will connect the mine with the mill. An electric power plant will be put in at the mill of sufficient capacity to provide all the light and power needed by the mine and mills. The company at present is milling 700 tons of ore daily. Plans for the new mill will be prepared at once, and it is hoped that it may be completed within fifteen months. During the progress of mill construction the mine will be further developed to supply the tonnage needed. Both the caving and the open-cut systems will be adopted, the latter involving the system of quarrying with steam shovels from open cuts as the great iron deposits are handled. D. C. Jackling is general manager of the company.

It is announced that a 500-ton addition is to be made to the Highland Boy smelter of the Utah Con. M. Co., at Bingham. The "M" ore body, opened on the 8½ level, has now been crosscut from wall to wall and is shown to be 130 feet in thickness, with the ore of uniform and average grade. The mine is sending down 850 tons of ore daily.—Manager J. E. Edmunds of the Copper Glance reports that the breast of the deep tunnel, started last season in McGuire gulch, east of Bingham, and now driven between 600 and 700 feet, is impregnated with mineral throughout, and that small streaks of ore carrying as high as 8% copper have come in.—The Teck tunnel, at the Boston Con., has now been driven 25 feet into the copper-bearing porphyry and the rock is improving. The carbonates have been replaced by sulphides and the rock at the face will average 2%, with many streaks of higher grade, including seams of chalcocopyrite.—The Butler-Liberal, at Bingham, has started up its air compressor and work has been resumed with the machine drills.

The Kempton mill, at Bingham, owned by E. A. Wall, is being remodeled, enlarged and improved. New machinery is to be added and the capacity increased from 90 to 150 tons daily. The added machinery will include two corrugated Wall rolls, making four rolls in all. After passing through the first set, the ore will be screened and put through the second set, instead of going through the same rolls twice, as heretofore, thus effecting a saving in labor and expense. The four old jigs will be thrown out and replaced by five new ones of improved pattern, which will make an over-size product for recrushing. Two more Wilfley tables also will be installed, making four in all.

## Sevier County.

By the recent joining of No. 4 and No. 5 tunnels of the Annie Laurie mine, at Richfield, the ores from all the upper workings may be dumped into No. 5 tunnel and transported direct to the mill.—The Trappers' Pride, near Richfield, owned principally by P. W. Madsen of Salt Lake, has been worked all winter. The vein has been followed 600 feet.—W. Johnston, W. Blake and W. J. Skelton have resumed work at the Copper Butte, near Richfield.

## Summit County.

The main shaft on the properties of the New York Bonanza, at Park City, has reached the 800-foot level, and crosscutting has been started to tap the channel.

## Uintah County.

The gravel bars in the Green river, near Jensen, are being worked after having been prospected during the past winter.

## Utah County.

A 5-foot vein of crystallized lead ore is reported in the breast of the upper tunnel of the Buckley mine in Rock canyon near Provo. In the lower tunnel, which will tap the vein about 300 feet below the upper tunnel, a large quantity of lead ore is being encountered in pockets and stringers in the limestone, and this is taken as an indication that the vein will soon be reached. B. F. Woodward & Co., who have a lease on the mine, have five carloads of ore ready for shipment.—The Provo Pressed Brick Co. has bought placer claims in the Lehi mining district from J. McCloskie of Provo.

## WASHINGTON.

## Ferry County.

R. L. Boyle, manager of the Keller & Indiana Con. Smelting Co. at Keller, expects that by July 1 all the

machinery for a 100-ton copper matte furnace, a 50-ton lead reduction furnace, a sampling mill and electrical plant for lighting the reduction works, the mine and the town of Keller, will be delivered. Electricity will be used to run the power drills in the mine. The dam across the San Poll river is completed and the 1½-mile flume is half finished.

#### Okabogan County.

J. E. Goibnov, president of the Grand View M. Co., near Loomis, has been at the mine examining development work done. An electric power plant to run the treatment plant and operate drills is being put in at Cecil creek, 1 mile south of Loomis. This work is in charge of S. Tollman. On Palmor lake a 20-stamp mill is being put up under direction of E. P. Chilson. It will be equipped with cyanide tanks and operated by electricity. It is 2 miles from the mine and the ore will be carried down by a tram.—At the Copper World extension a shaft is down 100 feet and a crosscut to the north has cut considerable ore. The contract calls for 200 feet more shaft work and 300 feet of crosscutting by Manager Bahrs.

I. H. Robb of Newark, Ohio, has started work in the Gladstone mine, on Pilot mountain, near Chesaw. He will also work the Mary Ann creek placer mines, where a hydraulic plant is being put in.

#### Snohomish County.

F. Peabody of Monte Cristo is building a surface tram 3000 feet from the Sidney mine to the railroad and hopes to begin shipping within sixty days.—The Index M. Co., L. Willbur president and manager, with office in Snohomish, is planning to add an air compressor to extend its tunnel, which is in 1200 feet.—The Imperial M. Co. at Silverton will start work. E. M. Stephens is president.

#### Stevens County.

J. Selmer of the Prudential mine on O'Toole mountain, 11 miles south of Northport, says that the Prudential is a gold property, with an iron capping. The tunnel is in 300 feet.—At the Pittsburg group, owned by Grutt Bros. of Davenport and Mulligan Bros. of Bossburg, a black, coal-like mineral, found in considerable quantities, is reported to be pitch blende. There is 800 feet of tunnel.

The Copper King mine at Chewelah has ceased shipments on account of the condition of the roads between the mine and the railroad. The company is arranging to put a traction engine between the mine and Chewelah with a capacity of fifty tons per trip and two trips a day. It is 5 miles from the mine to the railroad station.

## FOREIGN.

### BRITISH COLUMBIA.

#### Boundary District.

It is said that operations are to be started at the Stem-winder mine, one of the Brooklyn group at Greenwood. Air for several drills will be taken from the Granby pipe line, while the hoist in the incline shaft will be operated by steam. Work has been resumed on the Golconda group, South Deadwood, W. Hanna and J. Johnson having contract to drive 200 feet of tunnel. In previous work the tunnel was driven 300 feet.

Shipments from Boundary mines for week ending April 1 exceed that of last week a little: Granby mines to Granby smelter, 13,140 tons; Mother Lode to British Columbia Copper Smelter, 4256; Brooklyn to Montreal & Boston Smelter, 2702; Rawhide to Montreal & Boston Smelter, 1551; Mountain Rose to Montreal & Boston Smelter, 198; Emma to Nelson Smelter, 132; Oro Denoro to Granby Smelter, 66; Elkborn to Trail Smelter, 20; Last Chance to Montreal & Boston Smelter, 27; Skylark to Granby Smelter, 20; E. P. U. to Trail Smelter, 20; total for week, 22,132 tons; total for year to date, 238,240 tons. Smelters treated as follows this week: Granby, 12,476 tons; British Columbia Copper, 2738; Montreal & Boston, 4423; total for week, 19,637 tons; total for year, 236,239 tons.

The Montreal & Boston Copper Co., which recently acquired the Seattle mine, near Grand Forks, is working night and day forces to put this property on a shipping basis.—Peter Pare of Grand Forks has commenced work on his 125-foot tunnel on the Sunset fraction on Hardy mountain.—W. E. Zwicky, manager of the Rambler-Cariboo mine, near Sandon, says the company is continuing the development work it took up eight months ago to drive a tunnel 4400 feet to strike the 1450-foot level. It is in 2000 feet now.

#### Nelson District.

Manager A. H. Kelly of the Reliance G. M. Co., owning the May and June, the Reliance and four other claims carrying gold quartz, near Nelson, expects that his 50-ton cyanide mill will be ready to run in May. Agitation is by the Hendryx process.

The Second Relief mine, at Ymir, is reported to have started operations. G. H. Barnhardt is in charge.

#### Southeast Kootenay District.

J. Cronin, manager of the St. Eugene mine at Moyie, has ordered an air compressor having a capacity of 3000 cubic feet of air a minute and will furnish power for thirty machine drills. Boilers will also be put in that will have a capacity of 500 H. P. This will give the mine a 50-drill equipment, there now being twenty machine drills in use.

#### Vancouver Island.

It is reported that Chas. Ramsey and Dr. Roughshead will build dredges at Golden City, on the Saskatchewan river, 3 miles east of Prince Albert. Each is to have a capacity of 5000 cubic yards daily and will be operated by electricity.

## MEXICO.

#### Chihuahua.

The Compania Minera Ignacio Rodriguez Ramos, S. A., has 300 men working their lead and copper mines at Baca, under the superintendence of R. G. Aguirre. R. A. Luistro is manager.

#### Sinaloa.

The American-Mexico M. & D. Co., W. S. Dillon manager, at San Lorenzo is said to be employing 900 men at its mine and smelter. D. T. Parker is superintendent of the smelter and furnaces.—J. B. Heymes has twenty

men working the Mina Restauracion de San Juan at San Lorenzo.—At Cosola the silver-lead property of the Compania Minera La Prieta y Annexas is in charge of J. B. Hernandez.

## Personal.

J. B. BROWN is manager Rainier G. M. Co. of Warren, Idaho.

H. LAHIFF has returned to Calaveras county, Cal., from Europe.

N. G. WOLFE is running the Independent assay office at Clifton, Ariz.

WM. BALL is superintendent Lower Mammoth mine at Eureka, Utah.

J. H. SINCLAIR of Denver, Colo., is at the Le Roy mine near Custer, S. D.

E. J. KENNEDY is general manager Golden West M. Co. near Rochford, S. D.

M. HARMAN of Mansfield, Ohio, is manager at the Ruby mine, near Loomis, Wash.

J. J. CASE has gone to Cerro de Pasco, Peru, as superintendent Haggin smelter.

A. M. BREWSTER is assistant superintendent Viebach M. Co. in Oaxaca, Mexico.

W. E. HINDRY is general manager Esperanza M. Co. at El Oro, Mexico, Mexico.

D. H. LAWRENCE is consulting engineer Germania G. M. Co. of Idaho Springs, Colo.

H. L. JONES, general manager Antler mine, near Hill City, S. D., is East on business.

ALGERNON DEL MAR has gone to Greenville, Plumas county, Cal., from Silver Peak, Nev.

GEO. PIERCE of Denver, Colo., is manager Original Bullfrog M. Co., at Bullfrog, Nevada.

A. M. ROCKWELL has resigned the superintendency of the White G. M. Co., Tucson, Ariz.

A. J. UNDERWOOD is manager Lluvia de Oro G. M. Co. at Batopilas, Chihuahua, Mexico.

C. J. ALLEN has returned to the Monumental mine, near Granite, Or., from Portland, Or.

O. RYDEN is superintendent American-Mexico M. & D. Co., at San Lorenzo, Sinaloa, Mexico.

J. J. DEMING succeeds W. D. Southworth as superintendent Gold Eagle mine near Neil, Idaho.

E. E. CONNERY, president Continental mine at Vulcan, Colo., has been in Minneapolis, Minn., on business.

J. J. BENNETT has been appointed mine foreman De Lamar's mines at De Lamar, Owyhee county, Idaho.

C. C. MATTHEWS, superintendent Oregon Securities mine at Bohemia, Or., has been in San Francisco, Cal.

W. B. ROBERTS has assumed the management of the Goldfield Herald and Goldfield-Gladiator mining companies.

FERD. MCCANN is manager Grados M. Co. and the Guerrero M. Co. at Los Grados, Tlaxcopec, Guerrero, Mexico.

L. R. MEAD succeeds the late Geo. H. Wallis in the vice-presidency of the Mechanics' Institute of San Francisco, Cal.

H. HUGHS is superintendent Tecolotes mine of the Guggenheim Exploration Co., at Santa Barbara, Chihuahua, Mexico.

L. S. CATES has been promoted from the position of superintendent to that of mine manager for the Boston Con. M. Co. at Bingham, Utah.

V. NUSBAUM, secretary and treasurer Cleveland M. & M. Co., operating the California mines at Silver City, Idaho, has been examining work done at the mine.

H. J. CUNNINGHAM, manager Endless Chain M. Co., operating claims in the Harshaw district, Arizona, has gone to San Antonio, Texas, where he will enter a sanitarium.

L. W. TRUMBULL, Professor of Mining and Geology, School of Mines, University of Wyoming, has been appointed consulting engineer to the Strong Copper M. Co. of Leslie and Laramie, Wyo.

GEO. B. DAMON, who has been manager of the Wellman-Seaver-Morgan Co.'s New York office, goes to their main office at Cleveland, Ohio.

H. V. CROLL, recently Pacific coast district manager Allis-Chalmers Co., San Francisco, Cal., is now at 244 Equitable Bldg., Denver, Colo.

F. E. WADE of Lead City, S. D., general manager Globe M. Co., is in the East placing orders for the machinery for the company's mill.

G. H. SAVAGE, general manager Milwaukee Gold Extraction Co., on Flint creek, between Philipsburg and Anaconda, Montana, has been in Milwaukee, Wis., attending a meeting of the stockholders.

A. C. BUNKER AND W. C. APPLETON, alternating current engineers, have become associated with the Crocker-Wheeler Co., Ampere, N. J., in the engineering and contract departments, respectively.

W. A. STADELMAN, former manager Eastern office Brown Hoisting Machinery Co., is now manager of the general Eastern office of the Wellman-Seaver-Morgan Co., with offices at 42 Broadway, New York City.

SAML. JAMES is manager Amoloya smelter at Toluca, State of Mexico, Mexico, having resigned as superinten-

dent Ohio & Colorado Smelter at Salida, Colo. G. C. Griswold, formerly superintendent Globe smelter at Denver, succeeds him.

DR. DAVID T. DAY, Chief of the Mining and Mineral Statistics of the United States Geological Survey, and also chief of the mining exhibit at the Portland, Or., exhibition, has left San Francisco, Cal., for the East via Denver, Colo.

WM. A. POMEROY has returned from Western Australia to Palo Alto, Cal. He was manager of the Great Fingall Con.-Day Dawn, West Australia, and was sent for by Bewick, Moreing & Co. to Kalgoorlie to succeed Ralph Nichols as manager Great Boulder Perseverance mine.

E. W. PARKER, in charge of the Government coal testing plant at St. Louis, Mo., is in California investigating the coals of the Pacific coast, and making arrangements for the shipment of coal from the several coal producing regions of the coast to St. Louis for briquetting tests.

C. E. GRUNSKY, who resigned as city engineer, San Francisco, Cal., to be one of the Panama Canal Commissioners, has resigned therefrom and been appointed consulting engineer in the reclamation service connected with Federal irrigation, at an annual salary of \$10,000. Mr. Grunsky will reside in Washington, D. C.

W. A. PRITCHARD, formerly superintendent Keystone mine at Amador City, Cal., but who for three years past has been a manager of the Bewick-Moreing interests in West Australia, it is reported has resigned and is on his way to the United States, via London. The reasons for Mr. Pritchard's resignation are not stated.

## Commercial Paragraphs.

H. S. MANNING has sold his interests in the firm of Manning, Maxwell & Moore, Liberty street, New York, to his former partner, Chas. A. Moore.

A PYRITIC SMELTING FURNACE built by the Vencadora Mine Equipment Co. is in successful operation at the Fulton Iron Works, San Francisco, Cal.

THE C. O. Bartlett & Snow Co., of Cleveland, O., report about thirty recent sales, among them to the Western Ore Separating Co., Salt Lake City, Utah, a direct heat rotary ore dryer and a similar one to the Henrietta Cyanide & Dev. Co., Henrietta, Ariz.

THE Allis-Chalmers Co. is removing its general offices from Chicago, Ill., to Milwaukee, Wis. The company has four other works in three other cities, but the largest works are in Milwaukee, and there is where all any future expansion of the company's operations will take place.

AT Dolgeville, Cal., Alfred Dolge, during the past year, has made 100,000 pairs of felt shoes. There is no charge for beating, for the California sun furnishes warmth gratis. He figures that he saves \$20,000 a year on his factory costs over the costs in his former Dolgeville, N. Y., shop. The Dolgeville, Cal., shops are driven by electric power, at an approximate cost of \$25 per horse power per year.

ARRANGEMENTS have been completed between the Lazier Engine Co. of Buffalo, N. Y., and the Dubois Iron Works, also of that city, for the manufacture of the Lazier gas and gasoline engines. Arthur A. Lazier, former vice-president of the Lazier Gas Engine Co. and patentee of the engines, has secured the entire control, which will be known hereafter as the Lazier Engine Co., head offices in the Ellicott Square, Buffalo, N. Y.

THE Rapid-Economy Stamp Mill Co. of San Francisco, Cal., report installing an additional 3-stamp battery of Richards' rapid-economy stamp mill on the Gold and Silver mine near Kelsey, El Dorado county, Cal., and state that the owners of the property have satisfactory results from the operation of the mill already installed by them. In this mill the levers, which are used instead of cams, drop the stamps at a speed of about 200 per minute.

THE Ingersoll-Sergeant Drill Co. of New York write: "The last official act of the Panama canal commission before resigning was to close a contract with the Ingersoll-Sergeant Drill Co. of New York for fifty standard rock drills of that company's manufacture, complete with mountings and equipment, to be used in the removal of rock in the great Culebra cut through the crest of the isthmus. The commission furthermore authorized the same company to remodel a large number of the French-Ingersoll drills, built in France under the patents of the American manufacturers. These machines remain from the original equipment of the old French company formerly operating on the canal."

THE shop employees of the Crocker-Wheeler Co. at Ampere, N. J., have organized a beneficial association. Every employe who pays 10 cents a week to the association will be entitled to \$10 a week, for twenty weeks, during incapacity through illness. If he dies his family will receive \$100. The payment of 20, 30 or 40 cents a week entitles him to \$15, \$20 or \$25 respectively, with death benefits of \$150, \$200 or \$250. The company has offered to contribute an amount equal to the dues paid to the association. Thus, if \$6000 are paid yearly in dues, the income of the association will be \$12,000. The company does not require representation in the association, which will be run entirely by the employees.

THE Animas Water & Power Co., of Durango, Colo., is installing a large hydro-electric plant. The power house is 20 miles from Durango. There is an effective head of 970 feet available through 2800 feet of pipe. The initial installation is two 2250 K. W. Gen. Elec. generators, direct-connected to Pelton water wheels; provision has been made in the dam and head works for an ultimate development of 30,000 H. P. The present pipe line, one for the two units, is of sheet steel, varying in diameter from 44 inches at the upper end to 34 inches at

the wheels, and of thicknesses from  $\frac{3}{4}$  inch to  $1\frac{1}{4}$  inch. The pipe is all double buttstrap riveted, with triple riveting at the lower end, and is provided with flanged connections. The water wheel units, two in number, are of the "double-overhung" construction; each unit consisting of two Pelton wheels, one overhanging each end of the main shaft, with the engine-type generator in the center. Needle nozzles are used, operated by oil pressure, and with automatic governors. The wheels are approximately 8 feet in diameter, with centers of cast steel, turned all over and fitted with Pelton buckets straddling the periphery and secured to same by turned steel bolts driven in reamed holes. The buckets are fine ground and machined inside to obtain high efficiency.

## Books Received.

The April issue of Air Power, published by the Rand Drill Co., contains description of the Carnegie gas plant, describing the methods of installing the compressor, laying the gas pipe line, giving capacities and general data of interest to engineers engaged in this class of work. Economy in the operation of coal mine power plants by F. C. Weber, M. E., is a discussion on operating costs of interest to coal producers and operators. The method of boring the Laurel line tunnel in Pennsylvania is outlined. This number of Air Power also deals with a 300-foot air lift, the installation of which was attended with some unusual conditions. The paper will be sent by the Rand Drill Co., 128 Broadway, New York, N. Y., on request.

"Bimonthly Bulletin of the American Institute of Mining Engineers" contains regular announcements and technical papers. T. E. Schwartz contributes a discussion on the occurrence of ore in the Yankee Girl mine at Red Mountain, Ouray county, Colo., in which he concludes that the ores of the district occur in persistent chimneys to which Ransome's term "stocks" does not well apply. In the upper zones fracture planes were not much in evidence. The siliceous envelope of the chimneys, a marked feature in the upper levels, gradually disappears with depth. W. Lindgren describes the occurrence of stibnite at Steamboat Springs, Nev., H. O. Hofman and W. G. Magnus on detail experiments on the effect of silver on the chlorination and bromination of gold using different strengths of solution and varying proportions of gold, and silver. The data show that a supersaturated solution of chlorine in water acts more strongly than one that is merely saturated, that a supersaturated solution can extract a satisfactory percentage of gold from a gold-silver alloy containing as much as 20% of silver and that with the decrease of chlorine below 2.1 grams in 150 c.c. of water and the increase of silver above 10%, the extraction of gold falls off quickly. "The results of bromination show that bromine is an efficient solvent for gold, giving extractions of 99.8%, 98.2%, 96.6%, 93.2% and 92.2% with solutions of 8.97, 5.98, 4.48, 2.90 and 2.60 g. of bromine in 150 c.c. of water; when the bromine present sinks to 2.1 g. the yield in gold falls quickly to 34.2%, and then diminishes more rapidly. With concentrated solutions (2.8 g. Cl, equivalent to 6.0 g. of Br) chlorine is a slightly stronger solvent than bromine; as the solutions become less concentrated the dissolving power of Cl falls more quickly than that of Br," the latter being the more efficient solvent in dilute solutions. Other papers are "Open Hearth Manipulation" by A. McWilliam and W. H. Hatfield, "Comparison of Methods for Determination of Carbon and Phosphorus in Steel," "The Development and Use of High-Speed Tool Steel," by J. M. Gladhill, "A Special Form of Slag Car," by L. J. W. Jones and B. H. Bennetts, "The Case of Henry Cort," by Chas. H. Morgan, "Blast-Furnace Plant of the Elba Società Anonima di Miniera di Alti Forni at Portoferraio, Elba," and "Labor-Saving Devices in the Works Laboratory," by Ed. Keller.

## Obituary.

ROGER SHACKLETON, a pioneer mining man of Nevada county, Cal., died March 30 at Grass Valley, Cal., aged 76 years.

HENRY VIGARS died of miner's consumption at Telluride, Colo., March 28. Deceased was a native of Devonshire, England, and in his 45th year.

A. C. LAMB, superintendent Tres Amigos mine, near Tucson, A. T., was blown to pieces by an infernal machine while asleep on April 5. Several sticks of dynamite were placed under a corner of the house and a 5-foot fuse attached.

JAS. F. WARDNER died at El Paso, Texas, on March 30th, aged 59. "Jim" Wardner was a type of the modern Bedouin whose wanderings are only limited to his ability to "get there." He was a miner who delighted in taking big chances, and, if he lost, consoled himself by the knowledge that he could strike it rich somewhere else and that success was only deferred. Like others of his class he made and lost several fortunes and was buoyant and hopeful to the day of his death. He was known everywhere that mining is done, and whether in the Cœur d'Alenes, the Klondike, Panama or South Africa, he had countless acquaintances in a career that throughout was more interesting than prosperous, if the acquisition and retention of ready money he accounted prosperity.

## Dividends.

The Bunker Hill & Sullivan M. & C. Co., Idaho, \$75,000, payable 4th inst.; total paid since Jan. 1, 1905, \$375,000; total to date, \$2,646,000.

## Trade Treatises.

Double-Friction Coil Clutch Co.'s booklet describes their make of clutch with sectional drawings and full description. It will be sent on application to the company, 42 River street, Chicago, Ill.

Crane Co.'s advance circular describes Crane steam and oil separators; twenty-six 10 $\frac{1}{2}$ x13 $\frac{1}{2}$  sheets, printed on white enameled paper, handsomely illustrated. It will be sent to the trade upon request; ask for "Advance Circular No. 01," writing Chicago or San Francisco.

## Latest Market Reports.

SAN FRANCISCO, April 7, 1905.

### METALS.

SILVER.—Per oz., Troy: London, 25 $\frac{1}{2}$ d (standard ounce, 925 fine); New York, bar silver, 55 $\frac{1}{2}$ c, refined (1000 fine); San Francisco, 55 $\frac{1}{2}$ c; Mexican dollars, 46c, San Francisco; 43c, New York.

COPPER.—New York: Standard, \$15.50; Lake, 1 to 3 casks, \$15.37 $\frac{1}{2}$  to \$15.50; Electrolytic, 1 to 3 casks, \$15.37 $\frac{1}{2}$ ; Casting, 1 to 3 casks, \$14.87 $\frac{1}{2}$ . San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18 $\frac{1}{2}$  to 24c. London: £67 5s spot per ton.

Copper is again slightly higher, having both fallen and risen again within the week. There are those who believe that a higher price will soon be reached. The demand for the metal continues strong and the price is well maintained; still the market appears devoid of speculative features, probably because those inclined to speculate do not really believe that the metal will go much higher, and there is no reason to anticipate a much lower price under existing conditions.

LEAD.—New York, \$4.60; Salt Lake City, \$3.50; St. Louis, \$4.12 $\frac{1}{2}$ ; San Francisco, \$3.70, carload lots; 4 $\frac{1}{2}$ c 1000 to 4000 lbs.; pipe 6 $\frac{1}{2}$ c, sheet 7, bar 5 $\frac{1}{2}$ c; pig, \$4.85. London: £12 11s 6d  $\frac{1}{2}$  long ton.

SPELTER.—New York, \$6.00; St. Louis, \$6.15; London, £23 7s 6d  $\frac{1}{2}$  ton; San Francisco, ton lots, 6 $\frac{1}{2}$ c; 100-lb lots, 7c.

TIN.—New York, pig, \$30.20 to \$30.37 $\frac{1}{2}$ ; San Francisco, ton lots, 31c; 500 lbs., 31 $\frac{1}{2}$ c; 200 lbs., 32c; less, 33c; bar tin,  $\frac{1}{2}$  lb., 35 $\frac{1}{2}$ c. London, £139 10s 0d.

PLATINUM.—San Francisco, crude, \$18.50  $\frac{1}{2}$  oz.; New York, ingot, \$19.50  $\frac{1}{2}$  Troy oz. Platinum ware, 75 $\frac{1}{2}$  to 82c  $\frac{1}{2}$  gram.

QUICKSILVER.—New York, \$40.00 to \$41.00, large lots; London, £7 12s 6d; San Francisco, local, \$38.00  $\frac{1}{2}$  flask of 75 lbs.; Denver, \$45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6 $\frac{1}{2}$ c; extra, 17 $\frac{1}{2}$ c; genuine, 31 $\frac{1}{2}$ c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 20c; San Francisco, Plumbers', 100-lb. lots, 16.75c.

ZINC.—Metallic, chemically pure,  $\frac{1}{2}$  lb., 50c; dust,  $\frac{1}{2}$  lb., 10c; sulphate,  $\frac{1}{2}$  lb., .04c.

NICKEL.—New York, 55 $\frac{1}{2}$  to 60c  $\frac{1}{2}$  lb.; ton lots, 40 $\frac{1}{2}$  to 47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31 $\frac{1}{2}$  to 34c.

ALUMINUM.—No. 1, 99%, small lots, 37c  $\frac{1}{2}$  lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

### STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$16.35 to \$16.85; gray forge, \$16.65; San Francisco, bar, 3c  $\frac{1}{2}$  lb., 3 $\frac{1}{2}$ c in small quantities.

STEEL.—Bessemer billets, Pittsburg, \$23.00 to \$27.00; open hearth billets, \$23.00 to \$27.00; San Francisco, bar, 7c to 12c  $\frac{1}{2}$  lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6 $\frac{1}{2}$ c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails,  $\frac{1}{2}$  c  $\frac{1}{2}$  lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case,  $\frac{1}{2}$  c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6 $\frac{1}{2}$ c; do. in kegs, 7c.

LUMBER.—(Retail): Pine, ordinary sizes, \$24.00 to 5.00; extra sizes higher; redwood, \$28.00 to \$30.00; lath, 4 eet, \$4.50 to 5.00; pickets, \$21.00; shingles, \$2.50 for No. 1 and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00 to \$35.00.

LIME.—Santa Cruz, \$1.25 country, \$1.25 city  $\frac{1}{2}$  hbl.

CEMENT.—Imported, \$2.15 to \$2.65  $\frac{1}{2}$  bbl.; California, carload lots, \$1.90 f. o. b. at works; small lots, \$2.20  $\frac{1}{2}$  bbl. in sacks, 4 sacks to hbl., 5c for each sack returned.

NAILS.—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.55; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d, Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4d and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

### GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 7 $\frac{1}{2}$ c; Hallett's, 7 $\frac{1}{2}$ c; San Francisco, 1000-lb. lots, 9c; 300 to 500-lb. 9 $\frac{1}{2}$ c; 100-lb. lots, 10 $\frac{1}{2}$ c.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lot, Eastern and foreign: Wallsend, \$7.50; Brymbo, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8.00; Cumberland, \$13.00; Cannel, \$8.50; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13.00 in sacks; Sunnyside, \$8.50, long ton.

POWDER.—F. o. h. San Francisco: No. 1, 70% nitro-glycerine, per lb., in carload lots, 15 $\frac{1}{2}$ c; less than one ton, 17 $\frac{1}{2}$ c. No. 1\*, 60%, carload lots, 13 $\frac{1}{2}$ c; less than one ton, 15 $\frac{1}{2}$ c. No. 1\*\*, 50%, carload lots, 11 $\frac{1}{2}$ c; less than one ton, 13 $\frac{1}{2}$ c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2\*, 35%, carload lots, 9 $\frac{1}{2}$ c; less than one ton, 11 $\frac{1}{2}$ c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg.

CAPS.—3x, \$5.50 to \$6 per 1000; 4x, \$6.50 to \$7; 5x, \$8 to \$8.50; Lion, \$9 to \$9.50, in lots not less than 1000.

FUSE.—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c  $\frac{1}{2}$  set; 14 oz., 40s., 9 $\frac{1}{2}$ c.

CHEMICALS.—Cyanide of potassium, 98%–99%, jobbing, 23 to 24c  $\frac{1}{2}$  lb.; carloads, 23 to 24 $\frac{1}{2}$ c; in tins, 30c; soda ash, \$2.00  $\frac{1}{2}$  100 lbs.; hyposulphite of soda, 3 to 3 $\frac{1}{2}$ c  $\frac{1}{2}$  lb.; caustic soda, in drums, 3 to 3 $\frac{1}{2}$ c  $\frac{1}{2}$  lb.; Cal. s. soda, hbbs., \$1.10 to \$1.20  $\frac{1}{2}$  100 lbs.; sks., 90c to \$1.00; chlorate of potash, 12 to 13c; nitrate of potash, 6 $\frac{1}{2}$  to 7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2 $\frac{1}{2}$  to 2 $\frac{3}{4}$ c; powdered sulphur, 2 $\frac{1}{2}$  to 2 $\frac{3}{4}$ c; flour sulphur, French, 2 $\frac{1}{2}$  to 2 $\frac{3}{4}$ c; alum, \$2.00 to \$2.25; California refined, 1 $\frac{1}{2}$  to 2c; sulphide of iron, 8c  $\frac{1}{2}$  lb.; copper sulphate, 5 $\frac{1}{2}$  to 5 $\frac{3}{4}$ c; chloride of lime, spot, \$2.50 to \$2.75; sulphuric acid, in carboys, 66 $\frac{1}{2}$  B, 1 $\frac{1}{2}$  to 2c  $\frac{1}{2}$  lb.; nitric acid, carboys, 8c  $\frac{1}{2}$  lb.

OILS.—Lard, boiled, hbl., 60c; cs., 65c; raw, hbl., 55c; cs., 63c; Lucol oil, boiled, hbl., 51c; cs., 56c; raw, hbl., 49c; cs., 54c. Kerosene—Pearl, per gal., 19c; As, tral, 19c; Star, 19c; Extra Star, 22c; Ecocene, 21c, Elaine, 25c; Water White, in bulk, 12 $\frac{1}{2}$ c; Mineral Seal iron bbls., 18c; wooden bbls., 20 $\frac{1}{2}$ c; cs., 24c; Minera; Sperm, cs., 26 $\frac{1}{2}$ c; Deodorized Stove Gasoline, bulk, 16c, do., cs., 22 $\frac{1}{2}$ c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19 $\frac{1}{2}$ c; Lard Oil, E. W. S., hbl., 75c; cs., 80c; Neats-foot Oil, pure, hbl., 63c; cs., 78c; Sperm, crude, 63 to 68c; Natural White, 63c; Bleached, do., 57c; Whale Oil, cs., 52 to 57c.

BORAX.—Concentrated, 6 to 7c  $\frac{1}{2}$  lb.; powdered, 8 to 10c; fused, 20 to 25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5 to 6c  $\frac{1}{2}$  lb.; No. 1, 4 to 5c.

LITHARGE.—Pure, in 25-lb. bags, 8 to 9c  $\frac{1}{2}$  lb.

MOLYBDENUM.—Best, \$2.75  $\frac{1}{2}$  lb.

CHROMIUM.—90% and over,  $\frac{1}{2}$  lb., 80c.

PHOSPHORUS.—American,  $\frac{1}{2}$  lb., 70c.

SODIUM.—Metal,  $\frac{1}{2}$  lb., 50c.

BISMUTH.—Subnitrate,  $\frac{1}{2}$  lb., \$2.10.

URANIUM.—Oxide,  $\frac{1}{2}$  lb., \$3.50.

MERCURY.—Bichloride,  $\frac{1}{2}$  lb., 77c.

TUNGSTEN.—Best,  $\frac{1}{2}$  lb., \$1.25.

SILVER.—Chloride,  $\frac{1}{2}$  oz., 90c to \$1.00; nitrate, 55c.

RED LEAD.—500 lbs. and over at one purchase,  $\frac{1}{2}$  lb., 7c; less than 500 lbs., 7 $\frac{1}{2}$ c.

MANGANESE.—Black oxide,  $\frac{1}{2}$  lb., 2 $\frac{1}{2}$  to 4c.

MAGNESIUM.—Pure, N. Y., \$1.60.

FIRE BRICK.—Domestic, carloads  $\frac{1}{2}$  1000, f. o. b., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skew hack, \$30.00; circle, \$32.00.

FIRE CLAY.—Domestic,  $\frac{1}{2}$  ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, \$8.50.

## New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING MARCH 28, 1905.

786,088.—ORE PULVERIZER—E. H. Benjamin, Oakland, Cal.  
786,081.—FRUIT PRESS—H. Bollweber, Spokane, Wash.  
786,084.—SHEARS—A. E. Border, Los Angeles, Cal.  
786,774.—HEN'S NEST—C. H. Buckingham, Pico Heights, Cal.  
786,003.—BRICK CUTTING MACHINE—C. R. Coddington, San Rafael, Cal.  
786,021.—PAPER FOLDING MACHINE—R. B. Friend, Oakland, Cal.  
785,873.—CHAIN—R. G. Goldman, Los Angeles, Cal.  
785,879.—TIDE MOTOR—G. M. Helvin, Longbeach, Cal.  
785,950.—WHARF OR PIER—S. G. Hinds, S. F.  
786,239.—RAILWAY SIGNALS—J. D. Gordon, Riverside, Cal.  
786,216.—WIRE SPRINGER—W. H. Horner, Seattle, Wash.  
785,952.—BUTTER TRAY—A. C. Hummer, Seattle, Wash.  
786,141.—HONE—McGrall & Owens, Centralia, Wash.  
785,821.—PRINTING PRESS—E. N. Mills, S. F.  
785,825.—PRESSURE ROLLER—C. K. Orton, S. F.  
785,978.—BUTTER CUTTER—C. P. Ross, Seattle, Wash.  
786,084.—SCAFFOLD—C. J. Roy, Pasadena, Cal.  
785,771.—CHAIN DRIER—C. W. F. Steinmann, S. F.  
786,003.—SPEED INDICATOR—S. W. Walsh, S. F.  
785,985.—COUNTING APPARATUS—P. W. Walls, Covina, Cal.  
786,174.—CLAMP—F. O. Wood, Pasadena, Cal.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

WHARF OR PIER.—No. 785,950. March 28, 1905. S. G. Hinds, San Francisco, Cal. One-half assigned to Atlantic Gulf & Pacific Co. of same place, a corporation of West Virginia. The object of this invention is to provide such a construction for wharf, piers or other similarly supported floors or structures as to rigidly unite the floor portion with the vertical posts by which such portion is supported, by such union to strengthen the structure against the shocks of waves where thus exposed or to strengthen it against loads which may be carried thereon. It consists in the combination with the piles by which such structure is supported, of caps or heads, and means for connecting the horizontal and bracing beams of the wharf floor, and other details of construction.

BRICK OR TILE CUTTING MACHINE.—No. 786,003. March 28, 1905. C. R. Coddington, San Rafael, Cal. This invention comprises in a brick and tile cutting machine, a cutter comprising a rotary support and having radially-disposed pivoted frames, cutting means carried by the frames, said frames having a limited arc of movement about their pivots independent of the movement of their support and springs fixed to and removable with the frames as a unitary structure and coacting with the support and independent of the force of gravity to turn the frames about their pivots in the direction of rotation of the support. There are other details of construction which combine to form a new and useful device adapted to overcome difficulties hitherto experienced in this class of machine, and which improvements greatly increase the output of the machine.

PAPER FOLDING AND PACKAGING MACHINE.—No. 786,021. March 28, 1905. R. B. Friend, Oakland, Cal. Assigned to Interfold Paper Co. The object of this invention is to provide an apparatus by which paper may be cut into regular sizes and afterward folded into packages, in which each sheet is folded in the middle and the sheets interlock with each other from opposite sides, so that when one sheet is withdrawn from the package it rises and presents the edge of the next sheet in readiness for withdrawal. Such packages are usually employed for toilet or cigarette paper, which is cut into even sizes and is afterward placed in holders, from which it may be withdrawn, as above described. It consists of combinations of mechanism by which a continuous web of paper is cut into lengths, said lengths folded intermediate of their ends, and the folded sheets interlocked and formed into packages.

## Tucson, Arizona.

One of the largest and most attractive of the cities of Arizona is Tucson, in Pima county. Tucson is one of the oldest towns of the Southwest, a settlement having been made here by the early Spanish Jesuits, who established missions and villages throughout Mexico and the southwestern United States at various dates from 140 to 300 years ago. Casa Grande, a ruin, near Florence, in the valley of the Gila river, is one of the marks of a semi-civilization which existed here long prior to the coming of the Spanish missionaries. For many years Tucson was a military post and a distributing point for a large surrounding region. The city has 10,000 inhabitants, being the most populous city in that Territory. The city

View of Tucson, Arizona.

Another View of Tucson, the Metropolis of Arizona.

occupies a valley, though surrounded by mountains of moderate height, in which are many mines, all tributary to the town. A great improvement is noticeable in the city within the past five years. In 1899 the town consisted chiefly of low adobe and brick structures, but the accompanying engravings show the character of buildings in the business portion of the city. Brick, stone and concrete structures have been built rapidly and the town is still growing. The grazing and agricultural interests are of importance as well as the mines, and Tucson has become the distributing point for a large portion of southern Arizona and northern Sonora, Mexico, the international boundary being but a few miles distant. Tucson is on the main line of the Southern Pacific.

THE one important mining district of the United States where no large combinations of mines or mining capital has been undertaken is in the zinc-lead fields of Missouri and Arkansas. The mines there are for most part worked by small companies or individuals, often operated under the leasing system, and operations are in some instances of a somewhat primitive character, though not grossly extravagant. Still, in the main, this division of business, lack of uniformity in method and the expenses of management incident to this manner of carrying on mining operations makes the cost really higher than it would be under properly organized general direction of consolidated mines. Forty companies could be run under a single competent and experienced management and the economic results become more satisfactory than under the prevailing system. It is remarkable, with the opportunities which that field offers, that this consolidation of interest has not long since been effected. In this connection it is interesting to note that an electric power plant has been built in that district to supply light and power to the many mines, and that which heretofore has been one of the chief items of expense in the operation of mines and mills in the zinc fields will now be materially reduced.

AT the December, 1904, meeting of the California Miners' Association in San Francisco, Cal., several interesting papers were read, of practical value to mining men everywhere. The official report of the proceedings is just published, and in this issue some of the papers read are given the publicity attendant upon such appearance in this journal. Comment, rejoinder or additional remark is invited for similar publication, for in such interchange of opinion among practical men lies the largest possibilities for advance—for by discussion and comparison of methods the truth that "everybody is wiser than anybody" is most readily shown.

## Status of an Alien.

The question has again been raised as to what is the status of a title to a mining claim located by an alien who has not declared his intention to become a citizen of the United States, by the recent jumping of the Quartzite mine, near Goldfield, Nev. The proposition in general has several phases. The Federal statute distinctly says that mining lands are subject to location by "citizens of the United States and those who have declared their intention to become such." An alien may, however, purchase from a citizen locator, and hold the property until "office found." The Supreme Court of the United States has said: "By the common law an alien cannot acquire real property by operation of law, but may take it by act of the grantor and hold it until office found; that is, until the fact of alienage is authoritatively established by a public officer, upon an inquest held at the instance of the Government. The proceedings which contain the findings of the facts upon the inquest of the officer is technically designated in the books of law as 'office found.' It removes the fact upon which the law divests the estate and transfers it to the Government from the region of uncertainty and makes it a matter of record. It was devised, according to the old law writers, as an authentic means to give the King his right by solemn matter of record, without which he, in general, could neither take nor part with anything; for it was deemed a part of the liberties of England, and greatly for the safety of the subject, that the King may not enter upon nor seize any man's possession upon bare surmises without the intervention of a jury. By the civil law some proceeding equivalent in its substantive features was also essential to take the fact of alienage from being a matter of mere surmise and conjecture, and make it a matter of record. Such a proceeding was usually had before the local magistrate or council, and might be taken at the instance of the Government or upon the denouncement of a private citizen."

A citizen of the United States, or "one who has declared his intention to become such," acquires his title by complying with certain requirements of the law. The public lands are all the property of the Government, and the Government alone has the power to object to a location made by an alien, and to inquire into the qualifications of the locator. The Supreme Court has been called upon several times to pass upon the title of the alien locator and the conclusion is that a location made by an alien, who otherwise complies strictly with the requirements of the statute regarding the location of mining claims, acquires a title to such location, of which he can only be divested at the instigation of the Government by a legal process to which it is either directly or indirectly a party. When such title is acquired by a citizen, not even the Government can divest him of his rights so long as he complies with the requirements of the law. In cases of this nature, where the aliens have located mining claims, the Supreme Court has held that these locations were voidable (not void), and are free from attack by any one except the Government itself (*McKinley M. Co. v. Alaska United M. C.*, 183 U. S., 563, 572; 22 Sup. Ct. Rep., 84).

In view of these decisions of the Supreme Court of the United States, it is apparent that a citizen really has no legal right to enter upon and relocate a claim previously located by an alien. Notwithstanding this, the Supreme Court of Nevada has intimated that a mining claim located by an alien might be entered and relocated by a citizen (*Golden Fleece G. & S. M. Co. v. Cable Cons.*, 12 Nev., and *McEvoy v. Megginson*, 29 L. D., 164.)

Discussing the subject, "Lindley on Mines" draws the following conclusions:

"1. An alien may locate or purchase a mining claim, and until 'inquest of office,' may hold and dispose of the same in like manner as a citizen.

"2. Proceedings to obtain patent are in the nature of 'inquest of office,' and in such proceedings citizenship is a necessary and material fact to be alleged and proved.

"3. In all other classes of actions between individuals with which the government has no concern, citizenship is not a fact in issue, it need neither be alleged or proved.

"4. Naturalization of an alien at any time subse-

quent to either location or purchase is retroactive and enables him to proceed to patent; the antecedent bar to patent by reason of his alienage is removed.

"5. An alien may take title by descent to an unpatented mining claim in the absence of a State law inhibiting it. He may also hold such title until 'office found' and in conclusion says: "These conclusions are not altogether palatable, but we consider that they are forced upon us by the logic of the law.

ZINC is going up. The reasons for it are not apparent, for the production has been remarkably stimulated in the last two years by the successful introduction of several types of electro-magnetic separators, which afford a clean product of zinc blende from complex ores. With this great increase in production, the natural inference would be a falling market, while the reverse is the case. For many years the Joplin, Missouri, field has practically controlled the zinc market, but the now large and steadily increasing production of the Western mines has become an important factor. Last year the State of Colorado produced about \$4,000,000 worth of zinc, and other Western States and British Columbia a large amount. In the Joplin field, zinc is the principal mineral sought, and all the expense of mining is directly chargeable to that metal—lead being subsidiary, and precious metals being wholly absent. In the West, however, the zinc is in most cases a by-product, incidental to the mining for lead, copper, gold or silver, and the expense of production may therefore be considered as confined to the cost of concentration, transportation to the smelters and reduction charges. Formerly the zinc present in the ore was in many cases charged a penalty by lead smelters, and in consequence many mines carrying above 3% to 5% zinc were unable to ship that class of ore, and it went to the dump. Hundreds of thousands of tons of zinc bearing ore were thus accumulated and this is now being treated or will be treated in the future, while the present output of the mines producing this class of ore is treated as it comes daily from the mines.

THE coal mine disasters occurring lately in several Eastern States suggest that there must be something radically wrong in the conditions under which the mines are operated, which should receive the serious attention of the management. These accidents—so called—have nearly all been from explosions of fire damp, which is prima facie evidence that the ventilation of the mine workings is defective; that not enough pure air is driven into the mine to render the deadly damp harmless. It may be that the volume of air sent down into the workings is theoretically sufficient, but if so undoubtedly the distributing system is carelessly arranged, or lacks the necessary attention. Nearly all coal mines are supplied with elaborate ventilating plants for supplying fresh air to the workings, but unless the connections be properly made, some portions of the workings are likely to receive more fresh air than is really required, while other parts have too little. The fact that these deadly explosions occur in workings which have for months, possibly for years, been in daily use, indicates that a sufficiently close watch is not kept upon the daily, and sometimes hourly, changes in atmospheric conditions, which have a direct effect on the volume of gas present in the mine. The flow of gas is always accelerated when the atmospheric pressure falls, and what may be considered a fairly safe mine to-day, by reason of sudden atmospheric change, may become to-morrow a deadly trap, where a single mistake or bit of carelessness of one miner may result in an explosion which will wreck the mine and cause the loss of many lives.

SILVER has been given another jolt by the decree of the President of Mexico, who proposes to reform the monetary system of that republic. The Mexican mints cease free coinage of silver to-day. In view of this the silver producers of Mexico ask for relief from the present universal federal tax and the local municipal tax on their product. The depreciation occasioned by the operation of the new monetary system, which goes into operation May 1, justifies such request for further governmental action.

## CONCENTRATES.

COMPRESSED air is cheaper than steam for running machine drills under almost any circumstances.

TECHNICAL KNOWLEDGE, actual working experience and business ability are most necessary to success in the operation of a metallurgical plant.

ALL stock of corporations organized under the laws of California is assessable, regardless of what may be stated to the contrary by the prospectuses.

A ROCK TANK which leaks in a mine may usually be rendered tight by puddling clay in the tank, the fine silt closing the fissures or cracks through which the water escapes.

ONE of the largest electric generating stations in Germany is run by gas engines which derive the necessary supply of gas from the iron blast furnaces in their vicinity.

A 2-INCH machine drill in medium hard ground is often a very desirable machine to use in stoping small veins and in raises, owing to the facility with which they may be handled.

SOME of the most extensive coal beds of the West are found in Utah. The coal extends from the eastern boundary of the State, near Grand Junction, southwesterly into Arizona, nearly 200 miles.

OWING to the tendency of partly crossed belts to run off the pulley, when this arrangement becomes necessary to avoid such accident, the distance between the centers of the pulleys should be not less than twice the diameter of the largest pulley.

IF an air compressor is overloaded with drills, the air pressure at each drill will be lowered proportionally, and then the compressor must be speeded up to maintain the desired pressure, but under such strained conditions the economical limitations are soon reached.

THE several mesh standard mill screens are made of different sized wires. Thus a 35-mesh (1225 meshes per square inch) is made from No. 30 wire, and a 30-mesh (900 meshes per square inch) is made from No. 28 wire. A 20-mesh (400 meshes per square inch) is made from No. 23 wire, etc.

THE only material difference between massive and stratified tuff is that the former is deposited on the earth's surface and the latter either falls into water or is carried by streams into water, where a certain sorting action takes place, resulting in the stratification of the volcanic debris.

ALUMINUM is the lightest known metal, a cubic foot weighing 165 pounds, about the same as quartz. A cubic foot of mercury weighs 847 pounds and will float upon its surface all lighter metals, including copper, iron and lead. Gold and platinum sink in a mercury bath. A cubic foot of lead weighs 712 pounds.

NO CEMENT has been found which gives absolute security against decomposition by salt water, especially water containing sulphate, as sulphuric acid is the principal decomposing agent. Best results are obtained from Portland cement, low in alumina, free lime and gypsum, and by using coarse-grained, sharp sand.

IT is said that Commodore Peary, the Arctic explorer, who expects to make another effort the coming summer to reach the north pole, will carry the necessary apparatus to establish wireless telegraph stations along the route after leaving the ship. There appears to be little to prevent the carrying out of such a project.

THE effect of antimony sulphide in cyanide of potassium solutions is said to be the combination of a portion of the sulphur present in the antimony sulphide with potassium forming potassium sulphide, which is a very objectionable compound in cyanide treatment. The remainder of the sulphur combines to form sulphocyanogen.

SOME of the shafts in Lake Superior copper region have three compartments, where the end sections are used for hoisting, and the central compartment for manway, pipes, etc. The principal reason for this is to equalize the "travel" of the hoisting rope on the reel, or to make room for the hoisting engines and reels, if flat ropes are used.

THE amount of free air a rock drill requires per minute depends upon the size of the piston, length of stroke and air pressure at the drill. More air is consumed under high pressure (100 pounds) than under low pressure, but the drills run more rapidly and strike harder blows, and while this increases wear and tear in a somewhat higher ratio than where the drill

is run under relatively low air pressure, 60 to 70 pounds, the amount of work accomplished under high pressure more than compensates for the additional cost of repairs and of compression of the air.

THE wages paid a watchman on an idle mine cannot be charged to annual labor expenditure, unless it can be clearly shown that it is intended to resume operations within a short time. The watchman, moreover, should be employed in some active and useful work, such as rotimbering, or repairing buildings, etc., but this can only be done to a limited extent and in rare cases.

THE less the amount of dead work necessary in the operation of a mine the greater the likelihood of low cost per ton. The great masses of iron ore in the Lake Superior and Minnesota region require comparatively little dead work, though there are important exceptions. In some gold mines where the vein is small the greatest part of the expense is in the dead work required to search for new ore shoots and to keep the mine on a producing basis.

ALL concrete retaining walls, back of which water is likely to accumulate, should be provided with means for drainage. This is done by laying vitrified drain pipe underneath the base of the wall, so that the water accumulating there may be conducted away. A well built, 6-inch, concrete wall, made in the proportion of 1 of cement, 3 of sand and 6 of broken rock, will afford as much support to the earth as a 12-inch wall of brick. A wall of this character will support the pressure of 6 feet of earth. The wall should be built up inside of moulds, and allowed to set at least a week before the earth is filled in behind it.

THE present record of long-distance electric transmission is 345 miles at 60,000 volts, electric power having been transmitted from the De Sabla power house of the California Gas & Electric Corporation on Butte creek, Butte county, Cal., to Calaveras county, by Colgate, Oakland and Stockton. The power house contains three two-bearing type, hydro-electric generating units—two of 2000 K. W. and one of 5000 K. W. normal capacity. Water is conveyed from the reservoir, 1560 feet above the power house, by two 30-inch steel pipe lines 6000 feet long, delivering at a nozzle pressure of 675 pounds per square inch.

SPRINGS are usually the result of hydrostatic pressure, or gravity—practically the same thing. If water accumulates in a basin surrounded by a rim of solid rock formation, the water will saturate the gravels and loams of the basin, rise to the level of the encircling rocks, flow over at the low points in the rim, and usually flow out on surface at some lower point, as springs. Water confined in solid rock strata will flow out, forming springs, wherever the stratum holding the water reaches the surface at a point lower than the level of saturation. The appearance of springs is often miles away from the original source of the water.

IN the case where the vein is in the bed of the creek and running with it, the shaft should be sunk on the bank of the creek on the hanging wall side of the vein. Under such circumstances it is wise to sink a vertical shaft to cut the vein in depth, but such shaft should be located sufficiently far from the creek bed to reduce, as far as possible, the danger of the creek running through open fissures into the mine workings. Such a shaft should not cut the vein nearer than 150 feet from the surface, and a greater depth is advisable. Shafts have been sunk in the beds of creeks, the collar being surrounded by concrete, but this should only be done where no other course is open.

OFTEN a quick determination of the possible extraction of gold from an ore by the cyanide method is demanded of the assayer and cyanide operator. This cannot be satisfactorily given, as many ores require two to four days for the best economic extraction, and it is not to be expected that a higher extraction will be obtained by the use of ordinary solutions in the laboratory than in practice in the tanks. If a 60% extraction is obtained in twenty-four hours, it may be possible to greatly improve on this in the next twelve to twenty-four hours, with a still higher extraction on the third day. If accelerating materials are added to the solution, such as barium peroxide, a more rapid dissolution of gold may result, but the question as to the efficiency of this extraordinary method in practice must also be given consideration.

THE annual assessment work on mines in Arizona is governed by the United States laws. The location is made by erecting at or contiguous to the point of discovery a monument of stones not less than 3 feet in height, or an upright post projecting 4 feet above the surface of the ground, in which monument of stones or on which post shall be posted the notice of location, which shall be signed by the name or names of the locators. The notice must contain (1) the name of the claim located; (2) the name or names of the locators; (3) the date of location; (4) the length and width of the claim in feet, and the distance from the point of discovery to each end of the claim; (5) the general course of the claim; (6) the locality of the claim with reference to some natural object or permanent monument whereby the

claim may be identified. The law provides that until each of these things shall have been done no right to the claim shall have been acquired. From the time of locating the claim the locator shall be allowed ninety days within which to do, or cause to be done, the following things: (1) To cause to be recorded in the office of the county recorder in which the claim is situated a copy of the location notice; (2) to sink a discovery shaft 10 feet deep, and deeper if necessary to disclose mineral in place; (3) to monument the claim on the ground so that its boundaries may be readily traced.

UP to the latter part of 1904, the deepest vertical shaft in the world was the Tamarack No. 5, near Houghton, Michigan, the next deepest being the Red Jacket shaft of the Calumet & Hecla Company, also near Houghton. On Jan. 1, 1905, the No. 3 shaft of the Tamarack Company had reached a total vertical depth of 5066 feet. The No. 4 Calumet shaft is an incline 8100 feet deep, and is the deepest inclined shaft in the world. A winze below the lowest level of this shaft has been sunk 190 feet deeper, making a total depth on the conglomerate lode of 8290 feet. Calumet No. 2 is down 7000 feet on the incline. There are several inclined shafts on the Calumet & Hecla property exceeding 6000 feet in depth, and on the Tamarack there are two shafts 4450 and 4967 feet deep, respectively, beside No. 3, which is deepest.

THE linings for copper converters are made of quartz and plastic clay, the latter acting as a binder, to retain the lining in position, that it may withstand the effect of the blast and the violent surging of the molten matte when the air is turned in. The quartz for this purpose is generally crushed in a rock breaker, and the material passed through a trommel, which screens out all pieces  $\frac{1}{2}$  inch and under. The oversize is recrushed, and the coarse and fine mixed together with the clay. The lining does not stand well if all the rock be coarse, nor if all be fine. Experience has shown that the less clay that can be used in the hinder the better. The clay must be of good quality and plastic, although not necessarily fire clay. It is rammed by experienced men with heated iron bars. After ramming the lining should be slowly dried; if used while a large percentage of moisture is still present, it will soon require relining.

IN locating mining claims the prospector frequently "steps off" the several distances between corners and stakes. Unless the ground be comparatively level and free from obstructions, this is likely to lead to considerable errors in distance, particularly on the 1500-foot side lines. Many men consider a stride as 3 feet, when, in fact, few men stride this distance unless on a smooth road, and doing so intentionally. Ordinarily from 28 to 30 inches is the length of stride of the average man. It is better to measure the distance with a tape measure, stretching it tightly, for many woven tapes shrink about 1 to 2 inches in 50 feet. A steel tape is best, but if neither of these are available, a strong cord or light rope, the length of which is known, may be employed, but a length greater than 25 feet should not be used, as it is likely to stretch and make a greater error than in stepping off the distance. When pacing off any distance it is best to count every other step, say those with the right foot, putting the left forward first. In an ordinary stride 20 double paces equals 100 feet where each stride is 30 inches, and 300 such double strides will measure approximately the length of one side of a full mining claim—1500 feet. If it is intended to pace off ground in this manner, the best way is to measure off a given distance, say 200 feet, and then walk from one end of this to the other, taking just 80 strides to make the distance. If at first too few are taken, repeat it, endeavoring to shorten the stride a little so as to make the 200 feet in 40 double steps.

THE force and value of black powder is often overlooked in these days of high-grade nitro explosives. There are places where black powder, or the more modern "low" nitro powder, does the work required more satisfactorily and less expensively than high-grade powders will. In the case of moving or shattering large banks of gravel or comparatively soft and shattered rock, the low-grade explosives are often as effective as the high grade. At the Blue Point gravel mine in Yuba county, Cal., some years ago a charge of 50,000 pounds of black powder was laid, which dislodged 150,000 cubic yards of gravel. The powder was distributed in a system of drifts. The main drift, 3x4 feet, was run in 275 feet. From this there were lateral branches, six on either side, each 80 to 120 feet in length. The powder was fired by electric machine, the contact being made at ten different points. At the Dardanelles hydraulic mine, near Forest Hill, Placer county, Cal., 36,000 pounds of "low" nitro powder were fired in a single blast and dislodged 500,000 cubic yards of gravel. The face exposed was 175 feet high and 1000 feet long. The material was gravel of fairly even character, with comparatively few large boulders. Under this bank 1200 feet of drifts had been run, in which the powder was distributed. This charge was also fired electrically. Dynamite is comparatively ineffective when charged in small holes in gravel banks, but under some circumstances when placed in drifts in comparatively large amounts it has accomplished relatively more work than an equal cost in black or "low" nitro powder. An instance is cited where 3500 pounds of 40% dynamite broke 200,000 cubic yards of gravel.

Gold Dredging in Oroville District, Cal.\*

Written by L. J. HOBL.

Gold dredging is one of the recent methods for working the auriferous gravel deposits. The industry is still in its infancy, but, from all appearances, in a very healthy one, promising a steady growth and a long lease of life. New fields adapted to this method are being discovered, and with the progress of improvements in the application of the fundamental ideas involved, fields, which at present do not seem promising enough, will eventually become fit for exploration.

The first dredger in the Oroville district was built by the Risdon Iron Works for the Feather River Exploration Co., being a 3-cubic-foot bucket dredger, which was finished in March, 1898, and is still in active service. It was followed by the Plutus, a harbor dredger altered to suit the requirements of a gold dredger. This dredger was not a success and was abandoned shortly after going into commission. Almost contemporaneous with the construction of the Plutus, the Kia Ora and Marigold No. 1 were built, both of them being Risdon boats with 3-cubic-foot buckets; the former is still running, the latter was taken out of commission about a year ago. The next boat was the California, similar to the Plutus, and also abandoned some time after its installation.

Late in the year 1899, the advent of electrical power in the district gave an impetus to the dredging industry, and we find the boats built previous to that time changing from steam to electricity, and after 1900 there was no boat built in the district but what used electric power.

The boats built in the district from 1900 to the present time are below given in their chronological order:

Lava Beds No. 1, a dipper dredger built by the Marion Steam Shovel Co. Oroville Dredging Co., a dipper dredger built by local parties. Continental, a Bucyrus dredger, the first boat in the district with a close connected bucket line. Marigold No. 2, Risdon boat, 5-cubic-foot buckets. Indiana No. 1, a Bucyrus dredger of 3-cubic-foot buckets. Boston and Oroville, Nos. 1 and 2, Risdon dredgers of 5-cubic-foot bucket. Feather River Exp. Co., four Risdon boats of 5-cubic-foot buckets. Boston & California No. 1, Risdon boat of 5-cubic-foot buckets. Cherokee No. 1, Bucyrus boat, 5-cubic-foot buckets. American No. 1, Bucyrus boat, 3-cubic-foot buckets. Pennsylvania, 5-cubic-foot buckets. Golden State & Miners' Iron Works. Butte, Bucyrus boat, 3-cubic-foot buckets. Oroville Gold Dredging & Exploration Co., Risdon boat, 5-cubic-foot buckets. Indiana No. 2, Bucyrus boat, 3-cubic-foot buckets. Boston & California No. 2, Bucyrus boat, 5-cubic-foot buckets. Lava Beds No. 2, Bucyrus boat, 5 cubic-foot buckets. El Oro No. 1, Link Belt Machinery Co., 5-cubic-foot buckets. American No. 2, Bucyrus boat, 5-cubic-foot buckets. Central No. 1, Bucyrus boat, 3-cubic-foot buckets. Leggett No. 1, Risdon boat, 5-cubic-foot buckets. Boston & California No. 3, 5 cubic-foot buckets, Marion Steam Shovel Co. Viloro, Bucyrus boat, 5-cubic-foot buckets. Lava Beds No. 3, Bucyrus boat, 5-cubic-foot buckets, about completed. Oroville Gold Dredging & Exploration Co. No. 2, Bucyrus boat, 5-cubic-foot buckets, building.

The following table shows the number of boats in the Oroville district at the present day, their make and size of digging apparatus:

NAME OF COMPANY OR BOAT.	Bucyrus Boat.		Dipper Dredger	Golden State and Miners' Iron Works—5 Cu. Ft.	Link Belt Machinery Co.—5 Cu. Ft.	Risdon Iron Works.

One of the boats about ready to start.  
\* Boat under construction.  
† Bucyrus boat, with Risdon revolving drum.

\* Abstract Trans. Cal. Min. Assn.

In no State are there so many dredgers working as in California, and at no place in California are there more than in the Oroville district, where to-day twenty-eight are running, two about ready to run and at least four more contemplated.

The other fields in California invaded by dredgers are the following:

Yuba river, about 12 miles above Marysville. Bear river, near Wheatland. American river, below Folsom. Calaveras river, at Jenny Lind. Sacramento river, above Redding. Clear creek, a tributary of the Sacramento river, below Redding, where a suction dredger is operating. Trinity river, at Poker Bar and at Trinity Center. Callahan, Siskiyou county, Scott river.

DESCRIPTION OF DREDGERS AND GENERAL FEATURES OF DIFFERENT TYPES.—A gold dredger consists essentially of a boat provided with appliances for the handling of the boat, digging the material in front of it, disintegrating and washing it, saving the gold contained in it and delivering the debris in the rear of the boat in such a manner as not to interfere with the movements of the boat.

Gold Dredge in Operation, Oroville District, Cal.

From the manner in which the gravel is excavated and delivered to the disintegrating, washing and gold saving devices two classes of dredgers can be distinguished, namely, the dipper dredger, where one large bucket is used for excavating, similar to the steam shovel used for excavations for canals, railroad cuts, etc., and the continuous bucket or bucket and link type, where an endless chain of comparatively small buckets, running over suitable tumblers, is used for this purpose.

The foregoing table will show that there is only one of the former style of dredgers now in use in the Oroville district, and its discussion will be left out of this paper, for the reason that this type has become obsolete and is not likely to be adopted by anyone contemplating the installment of a modern dredger.

I will only say that the reasons for this abandonment are the small yardage handled by such a boat and the crowding of the gold saving appliances by the sudden discharge of a voluminous bucket.

The hull of the continuous chain type is rectangular in ground plan, with slightly reduced width of the bow of the boat, and is constructed of timber. No one in the Oroville district has figured on a steel hull, but dredgers going into Dutch Guiana are being constructed with steel hulls. On the bow of the boat rises the bow gantry, from which is supported the lower end of the digging ladder. About the center of the boat the main gantry supports the upper end of the digging ladder and the main drive of the bucket chain. This gantry in the case of the latest type of the Risdon boat is constructed out of steel plates and shapes.

To allow the digging ladder and its chain of buckets to descend to the bottom of the ground to be worked, the hull from the main gantry forward is in two parts, separated by an opening, called the well hole, in which the ladder travels up and down.

The stern gantry supports the tail sluices, conveyor ladder, spuds, if there are any, and all the gentries are securely tied and braced to each other.

The general dimensions of the hull are: Width from 32 to 40 feet, length from 76 to 116 feet, depth from 7 to 9 feet, according to the size of buckets used and depth of proposed excavation.

The bucket line, as already stated, is either a close chain, where bucket follows bucket, or an open one, where buckets and links alternate, the former being

used on all the boats with the exception of the Risdon. The speed of the bucket line varies from 42 to 52 feet per minute. As to the merits of the close chain as against the open, it will occur to the most casual observer that the close chain can dig more, as with the same speed there are more buckets delivered in the same space of time.

The only place where the open chain might have an advantage would be in ground containing very large boulders. The buckets themselves vary in size, shape and makeup, but it can be generally stated that a cast steel bottom piece, with sheet steel hood and manganese or nickel-steel lips, the latter with reinforced cutting edges, has been shown to be best adapted to the work so far.

The shape of the bucket is also important, and the best types are so arranged as to deliver the material freely and not carry any appreciable quantity back into the well hole. To arrive at this condition, it is of advantage to give the bucket hood a rounded shape as against an oblong one. The first dredgers built by all the manufacturers worked under the difficulty of having the bucket bottoms made too light

and they suffered severely on account of this. Whenever an existing dredger had to renew its bucket line a heavier pattern of bucket bottom was adopted, and particular stress was laid on the proper distribution of the added metal to such parts of the bottom showing an intrinsic weakness or a greater liability to wear.

The weakest portions of the bucket bottoms are the eyes and the parts coming in contact with the manganese or nickel-steel wearing plates of the upper and lower tumblers. The pins connecting the buckets to each other or to the links are made in different styles from different materials, varying in diameter from 2½ inches to 4½ inches. The material which has so far given the best results in the larger size pins is a steel of about 0.55 carbon, while manganese steel has shown good wear on the smaller pins and is quite extensively used for such.

The pins work against bushings, generally made of manganese steel, and so far this material has given satisfaction.

The lower tumbler of the Risdon boat is of pentagonal shape, while on the other boats it is hexagonal. It consists of two cast-steel cheeks mounted some distance apart on a connecting thimble, the cheeks being lined with wearing plates of manganese or nickel steel at the points exposed to a contact with the buckets. In modern practice the lower tumbler is connected rigidly to a shaft, turning in bearings fixed to the lower end of the digging ladder, early attempts to have the lower tumbler turn on the shaft having proved disastrous failures.

The details of the bearings vary again in different boats, provision being made in all cases to tie the two sides of the digging ladder together at the bearings, either by means of the lower tumbler shaft itself, or by separate devices, so as to keep the ladder from spreading. It can be said that these devices have proved the more efficient the simpler they were; and it might be stated that simplicity of the construction of details is the criterion of a good dredger.

The upper tumbler consists of a cast-steel core, mounted on the main driving shaft and provided with proper manganese or nickel-steel lining plates for engaging with the buckets, pulling them up and guiding them. The Risdon boats have a square up-

per tumbler, while the earlier Bucyrus boats, the Link Belt and others use a pentagonal shape. The latest Bucyrus boats have a hexagonal one. While from a purely theoretical standpoint the square shape is most efficient in dumping the bucket quick and effectively, practical working shows that with this type of upper tumbler there is quite a blow attending the settling down of each bucket on its bearings on the tumbler; this blow is less on a pentagonal tumbler and still less on the hexagonal one; on this latter, however, the material is not delivered as freely as with the others, especially does this hold good for ground containing clay in large quantities.

In the latest boats the upper end of the digging ladder is suspended from the upper tumbler shaft, which is good practice, as

the breaks occurred with a plate girder type, the other with a braced box girder. The ladder is provided with rollers for the support of the up-going bucket line.

As a rule, the diameter of these rollers is too small and they do not turn very freely, so that they are subjected to sliding friction, a condition which is as undesirable for the rollers as for the buckets sliding on them. There have been rollers made with mangause shells and they have given good satisfaction.

The main drive, that is, the drive actuating the bucket line, is generally efficient on all the boats. As a matter of fact, the motors in connection with this work, as a rule, are too large in capacity and, therefore, not economical. As will be shown later on, the

sudden large cave and does not strain the hull of the boat as much as a spud.

The spud, it is claimed, gives a better chance to work hard ground by holding the boat up to the work. There have been quite a number of failures of spuds in the district, and as a consequence, spuds were constructed which were entirely too heavy. To show the extremes I give the section modulus of three spuds: No. 1, used on a 3-cubic-foot boat, 288; No. 2, used on a 5-cubic-foot boat, 562; No. 3, used on a 5-cubic-foot boat, 1096. While spuds Nos. 1 and 2 were broken on account of faulty design, spud No. 3, which is working in exceedingly hard ground, has not shown signs of giving way, and probably will, it being about twice as strong as No. 2. After the excavated material leaves the buckets it is first received by a hopper, which in the modern dredger is arranged with a gravel cushion for the material to drop on, thus saving valuable steel lining bars, which were used in the earlier types and are still in use in some boats of more recent construction. From this hopper it is delivered into a revolving drum or shaking screens, where it is disintegrated and washed, the finer material falling through perforations onto the gold saving riffles, the larger stones and gravel being conveyed by the drum or shaking screens to the tailing stacker or conveyor.

The Risdon boats throughout use the revolving drum, the others, with the exception of two, the shaking screens. It is claimed by the advocates of the revolving drum that it disintegrates the material better, especially in clayey soil. While this may be true, there is to-day a great deal of such material handled successfully by shaking screens. The advocates of the shaking screen claim for it a better distribution of the material on the gold saving devices and cheaper repairs, also greater accessibility.

The question of drum versus shaking screen is one that must be decided from the nature of the ground likely to be encountered by the dredger, and even then there is a large margin left for individual likes and dislikes. A combination of the two might be advantageously employed by having the perforations in the drum of large size, thus eliminating only the largest gravel and boulders, then do the final grading on the shaking screen, thus accomplishing two objects, namely, relieving the shaking screen of a good portion of its load and of the tendency to clog, and separate at once the lumps of clay, which are always sluice robbers. The objection of bad distribution would also be solved by this method.

This drum could be improved upon by making it hexagonal or octagonal, so that the individual sections would be planes which could be replaced easier than curved sections. The water for washing is furnished by centrifugal pumps, mostly directly coupled to motors and this part of the dredger equipment is, as a rule, the most inefficient. From data obtained at various times by the author and others, the efficiencies of these pumps vary from 25% to 50%.

The fault is not altogether attributable to the pump manufacturers, as the exact conditions under which the water is to be delivered by the pump are not known to them with sufficient accuracy, but that they have never tried to determine by actual measurement just what these conditions are seems an anomaly. The importance of such investigation should be kept in mind, and it is hoped that before long we will be in shape to specify the conditions under which the pumps are supposed to work.

The riffles on which the gold is saved show in the modern style of boat a return to the well-known Hungarian rifle, with slight modifications to suit the conditions.

(TO BE CONTINUED.)

THE cost of producing copper at Rio Tinto, Spain, is stated to be about \$1.55 per ton, divided as follows: Mining, 80 cents; roasting, about 18 cents, including labor in building heaps, etc.; precipitation and collecting, about 56.6 cents. The cost of labor in that portion of Spain is low and supplies are nominal in cost. At these mines sixty-six tons of ore are required to produce one ton of metallic copper. The cost of producing one ton of metallic copper by the cementation process as carried on there is about \$144.

Bucket Ladder of Dredge in Operation.

Gold Dredge Working Inland, Showing Tailings Stacker.

the eccentricity of the suspension of the ladder at some point forward and below the upper tumbler shaft causes the buckets to leave the ladder rollers, which should guide them on the upper tumbler, whenever the ladder is not low down. The digging ladder itself is either of the plate girder type or a box girder stiffened by truss rods. In the case of the boats recently completed on the Yuba river it consists of a bridge truss made up out of angles.

The depth to which the digging ladder reaches varies from 30 to 60 feet below the water level, the latter depth being reached by the just mentioned boats on the Yuba river. While to my knowledge there have been but two cases where a ladder broke, they have been caused not by an intrinsic weakness of the ladder, but were secondary effects of a break in some other part of the appliances on the boat which caused the ladder to drop suddenly. One of

power used for the main drive is from 40 to 60 H. P., with possible peak loads for very short periods of 75 to 100 H. P., while the motors installed are from 50 to 100 H. P.

The winches governing the head and side lines or the side lines and the spuds, while differing in design, are generally efficient, only in the earlier boats they have been made rather too light in some details. In the more recent boats provisions are made for a fast speed on these winches to enable the rapid taking in of the slack of a rope. The Risdon boats throughout work on a head line, the Bucyrus boats, with one exception, on spuds.

The head line has the advantage of giving an easier distribution of the tailings and makes the use of the sand pump almost superfluous, an advantage particularly desirable in working against a high bank; it also gives the boat a chance to back out of a

## South African Methods.\*

Written by THOMAS H. LEGGETT.

There is certainly no other State in the Union than California that has contributed so largely in men and brains to the development of South Africa. The opening up, upon a true mining basis, of the De Beers diamond mines at Kimberley was begun in the eighties, under the direction of a Californian, Mr. Gardner Williams, a graduate of Berkeley, and the management has descended to his son, a graduate of the same institution; and in the gold mines of the Witwatersrand many of the most famous properties have been opened up by California consulting engineers and managers. Hence, it is natural that Californians in general, and California mining men in particular, should have kept more closely in touch with the work being done in these fields.

The main reef series, which is the payable series, has been accurately located over a length of 47 miles roughly east and west along the strike, and it is safe to say there is not a square inch of ground in that distance that is not owned by some mining company. To my mind, it is a fortunate thing that the mining laws of that country are so simple and direct. Each mining claim, which is in size about 155 feet by 413 feet, is bounded by vertical planes. There is no law of the apex and, in consequence, there has been an absolute dearth of mining litigation, while the mining law expert is an unknown quantity. In order to secure sufficient ground on the dip of the reef or vein, one simply locates parallel claims on the dip; and this latter, I may remind you, is often as flat as 15° to 20°, while on the eastern flank of the Rand, boreholes have shown it to be as low as 6° to 8°. The practical results of the working of this mining law have certainly been most satisfactory, and this in a country where the value of the mining claims has risen fabulously during the past ten years. For instance, claims lying on the dip of the reef, and where the latter lies at a vertical depth of over 5000 feet, have been sold for over £1000 per claim, equivalent to an area of a little less than one and one-half acres.

The outcrop mines are nearly all worked by incline shafts, and only a very few of these have as yet been worked out, those having an area of but a few claims. Behind these outcrop mines, that is to say, to the southward, on the dip of the reef, comes the first row of deep-level mines. Of these there are fifty-five vertical shafts, the average depth of which is about 1200 feet to the reef. There are fifteen producing mines now at work in this row. In the second row of deep-level mines the average depth of twenty-two shafts is 2600 feet to the reef, but thus far there are only two or three of these properties that have reached the producing stage. The average depth of the shafts in the third row of deep-level properties is about 4500 feet, and I do not know of any property in this row that has yet reached the main reef series. There are mines in this third row of deep levels that will require shafts 5000 feet deep, but 4000-foot shafts are now getting to be common on the Rand. These very deep shafts have called for the skill of the mechanical engineer perhaps even more than that of the mining engineer. Here again we find a Californian to the front in the masterly treatise of H. C. Behr, on "Winning from Deep Shafts." The usual deep shaft has four hoisting compartments, each 5 feet by 6 feet inside of timbers, and one pump and ladder way of 6 feet by 6½ feet. This is sometimes exceeded, as in my own experience, where the conditions permitted the working out of a single deep-level property of 260 claims through a single seven-compartment shaft. This shaft is now sinking to a depth of 4000 feet, and has six hoisting compartments. The record for quick sinking is held by R. M. Catlin in the Howard deep-level shaft of the Consolidated Gold Fields of South Africa, where he sunk 203 feet in one month in a shaft 28 feet 8 inches by 6 feet inside of timbers, and averaged 153 feet per month for a period of nine months, at a cost of about \$80 to \$90 per foot. In view of the deep mining now being done in the Lake Superior region, there has never been any doubt in the minds of the consulting engineers of the Rand but that the mechanical problems connected therewith could be readily solved.

But the question has naturally arisen as to what depth mining would ultimately reach on the Rand. This touches closely upon the matter of the gold contents of the reefs and their payability. With the object of endeavoring to form some idea of how much gold there was in the known area of these reefs, I, with Dr. F. H. Hatch, in 1902, prepared an estimate of the gold production and life of the main reef series down to 6000 feet. This does not mean that in our opinion the Rand reefs would be worked everywhere to a vertical depth of 6000 feet; but, as it was necessary to get some limit, and as it is evident that the reefs could be worked out to this depth without sinking a single vertical shaft of 6000 feet in depth, but by means of incline shafts at the bottom of the verticals from 4500 to 5000 feet deep, we felt it safe to estimate the gold contents to this limit. There is no doubt in my mind but that the miners of the Rand will feel their way to these greater depths in the future just as they have done in the past.

\*Abstract Trans. Cal. Min. Assn.

The profitable yield from the first row of deep-level mines encouraged the more strenuous development of the second row, the mines of which are now reaching the producing stage; and this, I take it, will be the case with the third and any successive row. My personal opinion is that beyond the third row of deep levels there will be very few vertical shafts, as it will be feasible to work out payable ground by long inclines from the bottoms of the shafts already projected and in course of sinking. One may naturally ask why this method has not been followed in the past and not so many deep-level companies formed. The reason is simply a financial one—that, so long as the reef lay within readily workable depths, the quicker the gold was extracted the more profitable the operation of extracting it became. Therefore, it is only now when greater depths have been reached that a halt has been called in the formation of these companies that now lie rank upon rank, one above the other.

Dr. Hatch and I found that from 47 miles of known reef there had been produced up to Dec. 31, 1901, £76,762,291, and there remains to extract to a depth of 6000 feet £1,233,560,709. The production of the Rand for 1898 was £15,141,000 and for 1899 it was at the rate of £19,000,000, the increase of production for the three years preceding the war being about £4,000,000 per annum. As you know, the recovery of the industry since the war has been extraordinarily slow. For 1903 the production was £12,589,000, and this year the production will be about £15,800,000. Before the war there were erected and in operation about 6400 stamps, while to-day there are erected and only awaiting the necessary labor to run 7500 stamps, with many more projected. The increase of stamping capacity in 1898 and 1899 was 2195 stamps, or about 1100 stamps each year; this rate of increase will, I think, soon be exceeded. Dr. Hatch and I estimated that in a very few years the annual production of the Rand would reach £30,000,000 per annum, and I think, in view of the foregoing figures of the enormous stamping capacity, you will agree that this is a very reasonable estimate. On the basis of this average annual production of £30,000,000, the life of the Rand would be about forty-two years.

It is on account of the regularity of the ore deposit that such immense capital expenditures as have been made on the Rand are permissible. At the same time, it is nothing like as regular as the reader of a descriptive account of the ore deposit is apt to imagine. The reef series is intersected by innumerable dikes, which cut through the strata at all angles. It is faulted and thrown very quickly, the throws sometimes amounting to a lateral displacement of hundreds of feet, while the sudden curving of the enclosing quartzitic sandstone, together with the capping of the later coal measures, has sometimes obliterated all trace of the reefs on the surface for distances of from 1 to 2 miles. Only by the most painstaking and persistent diamond drill boring have they been able to locate the payable reefs across such a gap as I have described. In consequence of these disturbances the underground work is sometimes most troublesome and complicated.

To attain the output indicated in the foregoing, of course additional labor is necessary. The Rand has been much hampered through the lack of sufficient labor. H. H. Webb has shown that before the war there were about 107,000 Kaffirs employed in the Witwatersrand mines. The Transvaal Chamber of Mines reports that at the end of October, 1904, there were 71,661 natives at work and 12,963 Chinese. The shortage of Kaffir laborers, as compared with the pre-war days, is, therefore, very considerable, and is due to a multiplicity of causes which it is not necessary to enter into here. Perhaps the chief cause is the reluctance of the Kaffir to work, and the explanation of this lies in the fact that wherever nature is prodigal in the products of the soil, life is rendered so easy that the average native has no necessity to labor. It is stated on good authority that there are 6,000,000 Kaffirs south of the Zambesi river, and yet it has always been difficult to get a sufficient complement of Kaffir laborers, not only for the mines, but for all industries in South Africa, and I presume this will always be so. This great need of labor has recently been met by the introduction of Chinese, and as this step has brought forth much severe criticism from people who are not fully aware of the conditions that call for it, I think it may be well to explain them here.

First, I may say that the introduction of the Chinese into South Africa is not at all on all-fours with their introduction into America, Australia or similar countries, and, for this reason, that in the Transvaal there exist already two distinct classes of labor, namely, that performed by the white and that performed by the black. The presence of the Kaffir in such overwhelming numbers establishes this distinction and nothing can change it. We all know that where white and black laborers come in contact there are certain things which the white man considers it "infra dig" to do, and the latter is most strenuous in maintaining this position. On the Rand the Kaffirs do all the drilling in the stopes, running of cars, shoveling, etc., and on the surface the firing of the boilers, shoveling in the cyanide tanks and similar labor, while the white man does the bossing. This has been so ever since the mines started. The

Chinaman in entering that country is not put into competition with the white man, but is put upon the lower plane of labor which already exists there. He is employed only at Kaffirs' work. Recently enacted and most strict legislation has so safe-guarded the white man in the Transvaal that there is not the slightest danger of the Chinaman ever going outside of his sphere of work. In America and Australia, on the contrary, as soon as a Chinaman lands he is at once in competition with all other classes of labor. It is evident, therefore, that one can not reason from analogy and exclude the Chinaman from South Africa as he has been excluded in the countries named, since the conditions are entirely and fundamentally different. Although I have not been on the Rand since the introduction of the Chinese, I learn from reliable sources that they are turning out most excellent workmen, and mines that have had their stamps hung up for the past two years—and even longer—are now able to resume operations. As for their physical well-being, fellow engineers inform me that they are most excellently taken care of; in fact, the danger is of erring too much in that direction. Hence, I think we can safely say that the introduction of the Chinese upon the Rand is a pronounced success. Chinamau are obliged to be returned to China at expense of the employing company at expiration of contract. This and all other gold-producing countries must now look to their laurels, for in a very short space of time it is certain that the gold output of the Transvaal will so greatly increase that it will head the list of the gold-producing countries of the world.

The situation in South Africa was desperate when this step of introducing Chinese was at last decided upon. Numbers of mines had in their treasuries working capitals of from £100,000 to £250,000, and were unable to expend a penny of it for nearly two years through lack of the required labor. If a condition of this kind confronted you here on the Pacific coast I am satisfied you would not theorize about it, but would speedily take action to meet it, and this is just what the people of the Rand have done.

In speaking of the working capital necessary for the development of the deep-level properties on the Rand, I am telling you nothing new when I say that the mines in the first row of deep levels have expended from two and a half to three million dollars each for development and equipment before getting out a single ounce of gold. But with a gold deposit of pebble conglomerate lying in sedimentary strata, and proved by boreholes to a depth of 4880 feet, to say nothing of the hundreds of miles of workings now existing, this comprehensive policy of mine development has shown itself to have been not only well founded, but commercially successful. At the same time, like all policies, it has its limits and can not be carried too far in exploiting the deep-level area of the Rand without inviting disaster; hence my remark that the miners of the Rand will undoubtedly "feel their way" in the exploitation of the greater depths before undertaking too heavy expenditures in deep shafts.

(TO BE CONTINUED.)

## Piping Air Into Mines.

The Pennsylvania Legislature has had under consideration a bill introduced in that body which provides for conveying air to workers imprisoned in the mines in case of accident. This proposed law requires that in all pits that shall be started for the purpose of mining coal or clay after January 1, 1906, when twenty or more persons shall be employed therein, the owners must run pipes not less than 6 inches in diameter beneath the floors of all tunnels. Pipes not less than 4 inches in diameter are to be run beneath the floors of all passages. These pipes must connect with the main tube and open into the various headings.

While the primary purpose of the bill is to supply pure air to imprisoned workmen, the tubes will also be used as a means of hasty communication, or as a means of transporting water in case of fire. Mine foremen must inspect the working of the tubes and see that the entire system is in proper shape. Inspections must be conducted at intervals of not less than seven days, neglect to do so on the part of the foreman being a misdemeanor. The punishment will be a fine of not more than \$100 or imprisonment for not more than ninety days, or both.

## One Cause for Misfires.

TO THE EDITOR:—At various times I have read in the MINING AND SCIENTIFIC PRESS items in regard to "missed holes" in blasting. The reason for this is that when fuze is used in a cold climate without being thawed it becomes hard, and when the miner who is blasting ore uncoils the fuze it is hard and stiff, very often cracking or breaking. This causes a missed hole.

If the fuze is put in a warm drying room, under a stove, or put in a powder thawer about an hour before using, this will soften it, so it will be readily pliable, and, when uncoiled, will not break or crack. I have found that by thawing the fuze in this manner missed holes are less liable to occur. F. O. ALM.

Internal Combustion Engines.

Written for the MINING AND SCIENTIFIC PRESS.

Countries where fuel is expensive naturally offer the most fertile soil for the growth of high-efficiency prime movers; hence England and Germany have in past years outstripped the United States in the development of the internal combustion engine.

Fig. 1 shows the acceleration of the use of gas en-

Fig. 1—Curve Showing the Growth of the Gas Engine Industry in 200 European Cities.

gines in 200 European cities between the years 1881 and 1902. The internal combustion engine is still in its youth in America and does not yet enjoy the full confidence of the public; but the popularity which these engines are winning in central station, street railways and other important industries is fast bringing the engineering profession to realize its true value.

In its growth the internal combustion engine has been divided into distinct and characteristic types through the influence of local requirements and fuel resources. General conservatism, however, stimulated by the heavy death rate of some new ventures in the industry, has brought it into prominence.

The four-cycle engine owes its origin to Beau de Rochas and Otto. To the former belongs the honor of first formulating rules for the design of an economical heat engine and to the latter that of embodying the theories of his predecessor in a commercially practical engine.

In the four-cycle engine the inspiration and compression of combustible gases and the expulsion of the burned gases is effected directly by motion of the main motor piston itself. When the piston has advanced about half way on its expansion stroke, the gas which was previously compressed on the in-stroke to the predetermined space provided in the end of the cylinder, and the combustion chamber having been ignited at the instant the crank passed center, the pressure of the gas expanding under the high temperature produced by its own combustion delivers its energy to the crank shaft. On the return stroke the exhaust valve is opened and the returning piston expels the burned gases. As the engine again passes center the exhaust valve is closed and the admission valve is opened, allowing a fresh charge to be drawn in. The gas and air are supplied to the mixing valve through separate regulating valves, the one being on the gas main and the other on the air line which terminates at the hollow frame of the engine, through which the air supply is taken, the metallic parts being thus cooled and the hollow frame acting as a silencer for the inflowing air.

The cylinder and combustion chamber are water-jacketed. High economy in gas engine practice depends on the degree of compression which can be carried or the amount of gas which can be made to occupy the clearance spaces of the cylinder and the combustion chamber at the beginning of the stroke. On the other hand, since the temperature increases quite rapidly with the pressure, and unless cooling methods are provided, the degree of compression at which the richer gases will ignite spontaneously will soon be reached. Obviously any heat carried away by the cooling water is lost, and no more cooling should be done than is absolutely necessary to admit of the desired compression.

Rich gases, or those in which the percentages of free hydrogen and volatile hydrocarbons are large, ignite at a much lower temperature than the leaner ones in which these constituents are less predominant. For the same cooling effect compression of the former gas can not be carried as high as that of the latter, and for the same degree of compression a greater cooling effect is necessary in the former case than in the latter.

Ignition is effected in both the four and two-cycle

engine by means of magnetos, the leads from which terminate in an ignition plug inserted in the cylinder head. These plugs, when pushed home, seat on an asbestos gasket and are secured by four studs. The stationary rod which forms one terminal of the magneto is insulated from the metallic portion of the plug by two tapered porcelain plugs. The movable rod which forms the other terminal of the magneto is free to turn in its bushings and actuated by the valve mechanism driven from the igniting gear shaft from

Fig. 2—Transverse View Four-Cycle Koerting Engine

Fig. 3—Sectional View of Koerting Gas Engine.

the main engine shaft. The mechanism which drives the magneto is so arranged that the armature is first turned slowly through about one-third of a revolution against a spring. At the instant the charge is to be ignited the magneto lever is disengaged, and the spring gives the magneto armature a quick jerk back to its original position, sending a high-pressure electrical impulse through the igniting plug terminals, which break contact at the proper instant, and the hot igniting force thus formed ignites the charge. In the larger size engines two igniters are operated in unison, and the large charges, being ignited at two points, insure uniform combustion.

Following is a report of tests made on the Koerting four-cycle engine. In these tests gas of about 500 B. T. U. per cubic foot was employed:

These engines are to be built by the De La Vergne Machine Co. of New York, which company has the exclusive right to manufacture and sell them in the United States.

THE PROSPECTOR.

"Gossan" is a Cornish term meaning iron capping of a vein. This is called by the French "chapeau de fer," or iron hat. Copper veins in regions that have been drained by nature often have a gossan, or iron cap, the result of the oxidation of the iron and copper sulphides. The copper leached from the partially oxidized ores, as the process of oxidation proceeds, is carried downward by the ground waters and is often found redeposited in the form of carbonates, oxides and enriched copper sulphides, such as bornite and copper glance. In geology a dike is a sheet or mass of igneous rock which has been intruded into older, pre-existing rocks. Quartzite is of sedimentary origin and therefore contemporaneous with the sedimentary rocks inclosing it, and cannot therefore properly be considered a dike, though often so spoken of. Miners also improperly speak of a limestone dike, sandstone dike, etc. Quartzite is not an igneous rock, but of sedimentary or aqueous origin. It varies in texture from very fine grained to coarse. It has usually a splintery to conchoidal fracture. Before being metamorphosed to a dense hard rock quartzite was a sandstone, and previous to that a bed of sand. The cementing material is usually largely silica, though iron and carbonate of lime may also be present. Quartzite occurs with limestone, slate, shale and various schists. Mica is also often present. Feldspar crystals are often seen in quartzite when it has been intruded by an eruptive rock. The condition described as occurring at Quartzsite, Ariz., may be due to the formation of several beds of sand alternating with several beds of fine mud on the floor of an ancient ocean, the sand and mud having subsequently metamorphosed into quartzite and slate, or a formation consisting of a single layer of quartzite, with slate above and below, might be compressed into a series of folds which would cause the several beds to be repeated where the upturned edges of the folds were exposed by erosion; or a series of faults might cause a single stratum of quartzite to be repeated on the mountain side. A series of such faults would be approximately parallel with the strike of the quartzite reefs. It is impossible to give the true explanation of the occurrence referred to without carefully examining the entire district. An intrusive granitic rock (aplite), which consists of quartz and feldspar, usually rather fine grained and containing little or no mica, is often mistaken for quartzite, particularly when the rock has been silicified, and pressure has rendered the rock somewhat schistose.

The rock samples from the Volcano mine, near West Point, Cal., are determined as follows: Nos. 1 and 2 probably originally diorite, now much altered, and consisting of chloritic scales and feldspathic mineral with veinlets of calcite. It may be a dike, or may be simply an alteration of the country rock. No. 3 is grano-diorite, somewhat altered. Nos. 4 and 5 are also grano-diorite, but greatly altered. No. 6 is a portion of the country rock and apparently lies in the zone of mineralization and may be considered a portion of the vein, as it carries abundant pyrite and quartz. No. 7 is grano-diorite, containing quartz, feldspars and hornblende. No biotite is observed in this rock.

The two mineral specimens from Placerville, Idaho, are determined as follows: No. 1 is principally pyrite (iron sulphide) in a gangue of what appears to be a feldspathic dike rock; the bright lead colored mineral resembling galena is jamesonite, a composition of lead, antimony and sulphur. No 2 is a feldspathic eruptive rock, probably felsite; it is somewhat altered and carries some pyrite, and is probably the same as the specimen No. 1, without the sulphide minerals.

Rock sample No. 1 from Silver Star, Mont., is quartz (white) with hematite (red). The green scale on one side is talc. No. 2 is an iron manganese compound—manganite. The composition of the mineral varies more or less.

The rock specimens from Poker Flat, Cal., are essentially the same thing. They are largely composed of feldspar, with the infiltration of silica, and iron sulphide. The rock is evidently of igneous origin, but too much altered to make determination definite. Such rocks are sometimes gold-bearing.

The rock sample from Leete, Nev., is pitch stone (not pitch blende). It is a glassy, volcanic rock.

## Mining and Metallurgical Patents.

PATENTS ISSUED APRIL 4, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

SMELTING FURNACE.—No. 786,121; P. Healey, Campbird, Colo.

Combination with double-walled blast furnace; of air pipe for introducing air between walls, and spraying device in air pipe located at point outside of point where air pipe enters outer wall of furnace for charging air with atomized spray of water and cooling inner wall thereby.

FURNACE.—No. 786,746; G. L. Fogler, Pittsburg, Pa.

Gas heating device comprising outwardly stack of refractory material, gas flue through stack, tuyere in furnace, gas flue connecting gas supply with tuyere, valve at bottom of gas flue, heat flue surrounding gas flue having inlet at its top and outlet at bottom, chimney connected with outlet, and pipe adapted to feed gas into inlet.

MINING CAR BRAKE.—No. 786,361; J. C. Jones, Coffeen, Ill.

Plurality of mining cars each having slidable bumpers, brake elements connected with said bumpers to obtain the automatic setting thereof, and means for effecting the manual setting of said elements, including a lever moved by the weight of an operator. Plurality of mining cars each having at each end slidable bumpers projecting at their outer ends beyond the car frames and carrying brake shoes at their inner ends, a foot-operated lever operatively connected with the mechanism to effect the manual setting of the brakes and means for releasing the

brakes. Plurality of mining cars having at each end slidable bumpers normally projecting at outer ends beyond car frame and carrying brake shoes at inner ends, cross-piece connecting each pair of bumpers, lever pivoted to car frame and having two arms pivoted to cross-piece and third arm provided with step and spring for releasing brakes.

ORE CRUSHER.—No. 786,265; A. C. Calkins, Los Angeles, Cal.

Ore crusher comprising frame forming crushing chamber open at front and bottom, and closed at rear and sides, vibratory jaw detachably and adjustably pivoted at heel to frame, and forming front of chamber, operating shaft at rear of chamber, reciprocating operating means extending from shaft alongside of chamber, and pivoted operating connection for vibratory jaw with such means, at top of chamber, jaw being movable on pivot, when lower pivot is detached, to swing out of open front of chamber and expose interior.

ROASTING FURNACE.—No. 786,567; W. R. Ingalls, Lynn, Mass.

Roasting furnace comprising two or more superimposed hearths, flues under two or more of hearths, ducts connecting flues, means to cause gas burned in flues to pass successively through them in circular direction; and rotary stirring mechanism with arms projecting over hearths, stirring mechanism consisting of central vertical shaft with interior flue, hollow horizontal arms passing through shaft and communicating with interior flue by suitable apertures, portions of arms exterior to central vertical shaft being inclosed by other hollow arms, so as to leave open space between inner and outer arms, and means for circulating a cooling medium through shaft and arms.

ROASTING FURNACE.—No. 786,599; C. H. Repath and F. E. Marcy, New York, N. Y.

In furnace having plurality of superposed hearths, fire chamber located beneath bottom hearth of series, and independent flues located within walls of furnace leading from fire chamber to series of hearths.

ORE SEPARATOR AND CONCENTRATOR.—No. 786,322; W. F. Stein, Fort Collins, Colo.

In machine of class described casing, concentrating pans arranged therein in oppositely inclined order, and doors carrying spacing elements projecting at different distances therefrom to hold pans properly positioned with relation to each other.

APPARATUS FOR SPRAYING BLAST FURNACE CINDER.—No. 786,573; W. Lessing, Geseke, Germany.

Apparatus for spraying glowing liquid blast furnace cinder, comprising in combination horizontally situated rotatable spraying drum, fixed on rotatable horizontal axle, fans projecting from surface of drum having undulated surfaces, adjustable channel for supply of material to be mixed with cinder, adjustable slag channel above drum, casing inclosing drum and accessories, having opening in upper part of casing for passage of slag channel, and having openings in walls of casing around ends of axle of drum.

PROCESS OF PURIFYING PIG METALS.—No. 786,048; J. B. Nau, New York, N. Y.

Process of purifying and enriching metals by pouring liquid metal upon mass of broken pieces of solid oxidizing material in such manner that liquid metal will be broken up and descend in small streams through spaces between and in contact with pieces of oxidizing material, causing a bath of liquid metal to accumulate, maintaining immersion of oxidizing material in bath, so that bath fills spaces in immersed mass of oxidizing material, for period desired, and separating liquid purified metal from oxidizing material.

STAMP MILL.—No. 786,590; A. McCombie, Grass Valley, Cal.

In stamp mill, vertically guided stamps and stems, crank shaft, ropes connecting with cranks, direction pulleys over which ropes pass, turnable connections between ropes and stamp stems and means including pivoted lever and connection operated from crank shaft for intermittently turning stamps during reciprocation.

### The Globe District of Arizona.

In eastern Arizona is one of the most noted and interesting copper districts of the Southwest. The most important mine in Globe district is the Old Dominion. This mine was discovered by venturesome prospectors who in 1874 crossed the Pinal mountains from the

westward. The Silver King mine was discovered by members of the same party on their return to Florence. The Silver King lies about 20 miles to the southwestward, on the west side of the range. Following this, discoveries were of frequent occurrence, and numerous small mining camps were soon established. The most of these newly discovered districts produced silver ore, but, with the exception of the

Silver King, few of them endured. The difficulties of existence on the desert, together with the depredations of the always hostile Apaches, were too serious drawbacks to be overbalanced by the promise of uncertain fortune. One of the noted districts of those early days was Richmond Basin, on the southwest side of the Apache mountains, its chief claim to notoriety being the finding of thousands of

View of Globe, Arizona.

Gravity Tramway, Clifton, Arizona.

Group of Mines, Globe, Arizona.

United Globe Mine, Globe, Arizona.

dollars' worth of nuggets of native silver, which occurred in the same manner as placer gold. Native silver and rich silver chloride ores were mined there, chiefly from the McMorris mine, for several years. McMillanville was also a noted and prosperous camp, owing its fame to the Stonewall Jackson mine, which also produced a large amount of native silver. The Silver King was the most permanent of these famous silver mines, being successfully worked to a depth of about 800 feet and producing several millions of ounces in silver. All of these mines are within the Globe region, but, singularly unlike the Globe ore deposits, the value of which is chiefly in copper. Globe eventually became the chief town and distributing point of the district. Gold as well as silver was produced by some of the mines of the district, but the first copper prospects were the Globe—later the Old Dominion—and the neighboring Globe Ledge, where a large amount of copper ore was exposed by superficial workings. The original Old Dominion mine is 4 miles north of the town of Globe. The ore occurs in quartzite. This mine is not that now known as the Old Dominion. It produced a considerable amount of gold and silver, as well as copper. It is owned by the Old Dominion Co., but has been idle for several years. The first development of copper on the Globe claim attracted little attention by reason of the isolation of the region, but in 1881 the Old Dominion Co. built a copper furnace, about 6 miles west of town, to work some ore found in schists near the smelter, but this, proving to be a bunch, was soon exhausted. The smelter was then removed and set up at Globe, where for some time it was run on the copper ores of the Old Dominion mine. This ore was too siliceous for profitable operation under existing conditions and the company bought the Globe mine, near town. In May, 1884, nearly 500 tons of copper were produced by two 30-ton stacks. The name Old Dominion was then attached to the copper mine in town and the original Globe was abandoned. The property, notwithstanding its promise, was sold at auction in 1886 for \$130,000. This was due chiefly to the low price of copper, the industry becoming unprofitable under existing conditions. Freight had to be hauled 120 miles from Wilcox, and the heavy expense could not be met with copper at 10 cents per pound. Circumstances compelled the closing of the mines. In 1892 a number of the most important mines of the district were consolidated under the title of the United Globe mines, but the Old Dominion has been and continues to be the most important property in the district. These two companies own the most important mines of the district. The copper ores occur in the southern end of the Globe hills and the silver and gold ores in the northern end of the same range.

The accompanying illustrations give a good idea of the character and topography of the country about Globe. The copper ores of Globe district are both oxidized and sulphide ores. Up to 1901 the oxidized ores proved the most important factor in the copper production of the district. Since then the sulphides have become of increasingly greater importance. This is chiefly chalcocite. Chalcocite also occurs, but, as far as known, not in large amount.

Malachite, the green carbonate, has been a very abundant ore in the Globe district; but azurite, the blue carbonate, is rarely seen there. Chrysocolla, the silicate, occurs in quantities of commercial importance. This ore is much lower in grade than malachite, owing to its large content of silica and water. It is found in many colors from light green through shades of bluish green to dark green and black, the latter color being due to manganese.

The Clifton district is also in southeastern Arizona, near the New Mexican boundary. The principal mines of the district are owned by the New England & Clifton Copper Co. One of the accompanying illustrations is that of a gravity tramway, showing one of the methods of surface transportation employed there.

### New Use for Acetylene.

It is stated by some German papers that a new use for acetylene gas has been found. The latest invention is its use as an explosive. By means of an air mixture explosive force is obtained, it is claimed, which can compete with that of powder and dynamite. The explosion takes place in an air chamber and is caused by an electric spark. For this purpose carbide of calcium is reduced to small particles and put into a tin box. In this the carbide lies at the bottom and above it is a partition filled with water. Above this is a vacant space with the electric percussion device. On the side of the cartridge is an iron pipe by means of which the partition between the carbide and the water can be perforated. After the drill hole has been completed the cartridge is placed in it and the hole is closed with a wooden stopper. Then the protruding iron pin is struck, by which the partition is perforated and the water is caused to come in contact with the carbide, whereby the acetylene gas is generated. This mixes with the air of the drill hole. After five minutes the gas is ignited by an electric spark. By this method of blasting the rock is said to be not thrown out, but rent with innumerable cracks, so that it can be easily removed afterwards.

## Treating Concentrates by Pan Amalgamation at the Minas del Tajo, Mexico.

Written for the MINING AND SCIENTIFIC PRESS by  
A. E. DRUCKER.

In a former article published in the MINING AND SCIENTIFIC PRESS some months ago, a description of the pan process as used on Tajo ores was given, also some causes for the "flouring" of quicksilver, and the remedies used for reducing such losses to a minimum. I shall now endeavor to describe a process for working fresh or oxidized concentrates, as used by myself at the Tajo, and probably it may be of some use to others working under the same conditions.

Formerly the concentrates produced at this plant had never been worked successfully in the pans, but were sent to the nearest smelter for treatment. This, however, was a very unsatisfactory method, owing to the excessive transportation charges, smelting rates, and a large amount of mercury lost through smelting—otherwise saved by the pan process. Something had to be done, and so the pan method was tried; it proved to be the best means, not only by saving a greater portion of the values, but also of saving quicksilver which amounted to several flasks a month.

**CHARACTER OF THE CONCENTRATES.**—At this mill concentration took place after amalgamation of the free gold and silver values. The tailings from the settlers were run over the Wilfley tables and the concentrates containing galena, chalcopryites, iron pyrites, zinc blende and "floured" quicksilver saved. The percentage of concentrates with the Tajo ores ranged between 3% and 10%, and the ore at times was very base. More than one-half of the values were contained within the floured quick, and these are the values that are saved mainly by pan amalgamation and not (to any extent) those combined mechanically or chemically with the concentrates. Some of the old concentrates were very rich in floured quicksilver. We had 1000 tons of these oxidized concentrates to work, which had accumulated in former years.

**ZINC AMALGAM AS A MEANS FOR COLLECTING FLOURED MERCURY.**—While experimenting with the concentrates in a small laboratory pan, it was found possible to run floured mercury together by the use of zinc amalgam, salt and bluestone, varying the amount of bluestone according to the conditions of the concentrates (fresh or oxidized). The action of zinc amalgam on floured quicksilver was first discovered by trying a simple experiment. Quicksilver, salt (NaCl), bluestone (CuSO<sub>4</sub>), and water were added to a test tube and agitated, and it was found that the mercury was soon finely subdivided, and that subdivision continued until floured mercury resulted. The globules were coated with a dark gray film of calomel (HgCl), it being formed by the action of cupric chloride on mercury. The reactions are:

and

While the quicksilver was in this condition, a very small piece of zinc amalgam was added and almost instantly the floured mercury joined with the larger particles to form one large bright globule of mercury. Zinc amalgam has the power of dissolving and cutting the calomel film, thus causing the immediate reunion of the finest quicksilver particles.

This property of zinc amalgam was made use of on a large scale, and we immediately set to work experimenting on some old oxidized concentrates. Our apparatus consisted of two iron pans, 5x3 feet, and two settlers, 8x4 feet, having a capacity of eight tons per twenty-four hours. At first our experiments were failures, but through perseverance and many trials, we succeeded in getting all parts of the process adjusted, so that a complete saving of the floured quicksilver was made.

**TREATMENT OF OXIDIZED CONCENTRATES.**—The concentrates originally containing galena (PbS), chalcopryite (CuFeS<sub>2</sub>), iron pyrites (FeS<sub>2</sub>) and zinc blende (ZnS) were badly oxidized, especially the copper and iron pyrites, which make up about 30% of the product. This necessitated a complete change from the ordinary process of working ores, the amount of bluestone, speed of the miller, time of grinding and amalgamating, temperature of charge, speed of settlers and the forms of settler shoes all being changed. It was necessary to use one settler for each pan, instead of two pans to the settler, which was the common practice with ordinary ores. Three hours were required for grinding and amalgamating, while the settler took the same time to work off the former charge of concentrates successfully. At first two hours were consumed in grinding and one for amalgamating, then two hours for grinding and two for amalgamating, and finally one hour grinding and two for amalgamation was found to be the best economic arrangement. The increase in extraction, due to a longer amalgamation than two hours, did not warrant the increased expense of treatment. Practi-

cally all the attainable values were extracted after two hours amalgamating. A somewhat greater extraction was obtained by grinding two hours in the pans, since fine grinding liberated some of the free gold that was mechanically combined with the sulphurets. However, I believe the increase was due to this fact alone, since the extraction increases in proportion to the amount of grinding and fineness. Excessive grinding did not pay, for the time consumed, and the additional expense more than offset the values obtained.

**AMOUNTS OF BLUESTONE, SALT AND ZINC AMALGAM NEEDED.**—Sixty to seventy ounces of bluestone (CuSO<sub>4</sub>), according to the degree of oxidation of the ore, were used on working the oxidized concentrates. The amount of CuSO<sub>4</sub> needed depended upon the color and condition of the quicksilver particles. In the case of oxidized concentrates, when the mercury in the pans becomes yellow, add more (CuSO<sub>4</sub>), or some zinc amalgam to get rid of this yellow coating on the quicksilver. It was absolutely necessary to remove this coating of the mercury if we expected to collect any or all of the "floured" quicksilver. I noticed that when oxidized concentrates were worked and sixty ounces CuSO<sub>4</sub> used, we got a very pure amalgam, the reason being that all the metallic iron particles (from wearing of shoes and dies) within the concentrates were oxidized and could not reduce the copper chlorides to copper, thus filling the amalgam with copper. While in the case of fresh concentrates we got impure amalgam containing copper, due to this reducing action of iron. About five times the amount of bluestone required for ordinary ores (twelve to fourteen ounces) was needed in the working of the concentrates. Our concentrates were made up mainly of galena and zinc blende, being one of the causes for using larger amounts of bluestone, since both of the chlorides of copper decompose these two sulphides.

The regular amounts of salt (NaCl) and mercury, as used with our ordinary ores, were employed in working the concentrates. Twenty pounds of salt and two quarts of mercury were found to be the proper amounts for each one-half ton charge. The bluestone and salt were put into the pan shortly after the concentrates were charged, and the proper amount of water added, the miller being lowered, the charge heated to 80° C., and all ground for one hour. At the end of this time the miller was raised, quicksilver added, and amalgamation continued for two hours. When the amalgamation was completed the charge was drawn into a settler and there worked off gradually for three hours.

Always add the quicksilver through a bag so that it can be finely distributed at once throughout the charge. By doing so it will take less to do the work and better satisfaction is given all around. One-half ton of concentrates was found to be enough to put in the pans at one time, as a better circulation and mixing of the pulp was afforded, thereby causing the quicksilver particles to come in contact with all parts of the charge.

No caustic soda (NaOH) was used in treating the concentrates, for extra precautions were taken to guard against grease getting into the pans. NaOH precipitates a hydrate of copper, Cu(OH)<sub>2</sub>, from the cupric chloride solution (CuCl<sub>2</sub>) which is not desired.

Zinc amalgam was required in different amounts, according to the appearance of the mercury particles during amalgamation. On panning out some of the charge, if the mercury had a yellow coating—film of oxides, probably—more zinc amalgam was required to remove it. As long as this film remained, plenty of floured mercury could be seen with the coated quicksilver particles on panning, but when removed it did not seem to take long in collecting all the floured mercury. This was a very important point and upon it depended the success of the process. All the way from three to eight ounces of zinc amalgam were required to the charge, the amount depending on the degree of oxidation of the concentrates. It was always added with the quicksilver in which it dissolved.

Zinc amalgam is prepared by taking sheet zinc and cleaning with a very dilute solution of sulphuric acid, adding all (zinc and solution) to an iron pot containing a flask of mercury, and heating slowly over a fire. The zinc will readily amalgamate, and the amalgam gathered on top of the mercury can be lifted out and squeezed dry. The operation can be repeated until all the mercury is absorbed or enough amalgam produced, being careful not to let the weak acid solution all evaporate and cause the quicksilver to boil. The solution on top prevents mercury fumes from being formed and also keeps the zinc clean.

**PROPER TEMPERATURE AND THICKNESS FOR THE CHARGE—SPEED OF PAN MILLER.**—The charge was heated at the start to 80° C. with steam from the boilers. At this temperature the chemicals performed their work more satisfactorily and the amalgamation took place rapidly. When the temperature is low, the mercury is less active and amalgamation goes on slowly. High temperatures cause losses in quicksilver and an unsatisfactory amalgamation. It was necessary to use steam heating, since the miller only made sixty-five revolutions per minute, and at that speed it was impossible to bring the temperature up to the required point.

The thickness of the charge is a very important

matter. If the charge is too thin the particles of quicksilver will not be kept in suspension, resulting in very poor amalgamation. The charge will also become cold, which should be avoided. On the other hand, if too thick, there will not be a proper circulation of the quicksilver particles throughout the charge. When the proper thickness has been attained, the pulp will just run from a dipper slowly and the mercury particles will be seen coming to the top and circulating all through the pulp.

Sixty-five revolutions per minute was found to be the proper speed for the pan muller while working either fresh or oxidized concentrates, and less than this speed would not cause a proper circulation of the pulp and quicksilver.

It can always be known when a good saving has been made by simply panning a little of the concentrates before discharging. If no floured mercury is seen, then a satisfactory amalgamation has taken place. Generally all the floured quick has disappeared some time before it is proper to discharge the pan. On panning out some of the charge before the quicksilver was added, considerable floured mercury could be seen. We also obtained from working these concentrates several flasks of mercury a month.

In treating fresh concentrates we were not troubled with the yellow coating on the quicksilver particles during amalgamation, which was the case with old concentrates. They were taken direct from the concentrators as fast as produced and worked in the pans. The only change from the above process was the smaller amount of bluestone used (fifty ounces).

**SETTLERS, BEST ARRANGEMENT AND FORM OF SHOES.**  
—The following forms of shoes were experimented upon with various results: Nos. 1, 2 and 5 were

very unsatisfactory, producing large losses in quicksilver. Forms 2, 5 and 7 have a tendency to keep the mercury particles up and throw out large amounts through the discharge holes of the settler. No. 1 was very suitable for working ordinary ores, but with heavy concentrates the settler could not be kept clean at the bottom, so as to cause a perfect separation between concentrates and quicksilver. The settler should never be allowed to foul by accumulation of heavy concentrates at the bottom. It is a positive preventive of good work and a perfect separation. Nos. 3 and 4 were a slight improvement, but not thoroughly successful. No. 6 was found to be the proper form of shoe, and was finally used in working up all the concentrates. It produced a less loss of quicksilver than any of the other forms, after being adjusted to the proper speed.

The settler must have a certain speed to correspond with the number of shoes used. With four arms to the muller, use fourteen shoes (type 6), arranged as in Fig. 8, having a speed of twelve revolutions per minute.

With six arms, use eighteen shoes (type 6), as shown in Fig. 9, and a speed of ten revolutions. Four arms and ten shoes will need fourteen revolutions. The arrangement as in Fig. 8, twelve revolutions per minute, was found to give good satisfaction. If the concentrates had a tendency to bank up at the center of the settler, it was found helpful to incline the face of the shoes (those next to the center) on the arms, as shown in Fig. 10. The velocity of the water increases gradually from the center towards the outer circumference of the settler. Sulphide particles that would float, and be kept in suspension at the outer circumference, would sink to the bottom of the settler towards or near the cone (center). The inclined shoes push the settled concentrates outward into the stream, where they are obliged to float, thus keeping the settler always clean at the bottom.

There is a certain current velocity at which a perfect separation of the sulphides from the mercury particles is effected. The velocity of the water should be such that the heaviest sulphides will just be kept in suspension, while the particles of mercury of a greater specific gravity are precipitated and collected with the mercury at the bottom of the settler. For good results, mercury should not be allowed to escape through the two upper discharge

holes, and a very slight amount, if any, should escape from the third (lower) plug hole. Panning will detect such losses.

The settler should have a form of cone as in Fig. 11,

FIG. 11.

since the concentrates are not allowed to gather ("bank up") at the center and cause trouble. The form of cone shown in Fig. 12 is not satisfactory. If

FIG. 12.

FIG. 13.—SETTLER SHOWING SHOES.

the discharge boxes on the settlers are lined with copper amalgamating sheets, almost all floured quicksilver escaping will be caught on them.

The three hours required for the settler to work off a charge is divided up as follows: After the concentrates have been discharged into the settler and the proper amount of water added, it is allowed to run fifteen minutes before removing the upper (first) discharge plug, causing a settlement of the mercury particles. Then the discharge takes place for forty-five minutes through the first (upper) hole, one hour through the second, and finally one hour discharging from (lowest) third hole. The settler is now plugged up and made ready for the next charge.

Summing up all of our results, we arrived at the following conclusions: That the best possible results were obtained when—

1. Keeping the charge at a temperature of 80° C.
2. Having the charge at a certain consistency so that it will just run from a dipper with difficulty.
3. Having the pan muller revolve at sixty-five revolutions per minute.
4. Working in the pan not more than one-half ton of concentrates at a time.
5. Using sixty to seventy ounces of bluestone with oxidized and fifty ounces or less with fresh concentrates—twenty pounds of salt used in both cases.
6. Always using a small amount of zinc amalgam with the quicksilver and two quarts of mercury with each charge.
7. Adding the quicksilver through a bag.
8. Grinding one hour and amalgamating two.

#### IN THE SETTLERS.—

9. Using the arrangement as shown in Fig. 11 for the settlers, and also inclining the shoes as in Fig. 10 (twelve revolutions per minute for muller).

10. Employing the form of settler shoes as shown in Fig. 6, made of cast iron.

We were able to make a saving of 56% to 70% of the values, (which was better than shipping) all depending upon how rich the concentrates were in floured quicksilver. The concentrates would run all the way from \$45 to \$80 per ton in value. The tailings (concentrates) from the settlers would average from \$19 to \$24 per ton, and were values that could not be saved by pan amalgamation. They were, however, impounded for a possible future cheap method of treatment.

THE Mexican Government has under consideration the proposition to establish a series of ore-treating establishments throughout the country at points remote from railways, and in the neighborhood of low-grade mines, which, through lack of transportation facilities, are at present entirely cut off. These plants are to be operated as intermediary between the miners and the smelting plants. The erection of one of the plants at an isolated mining camp will be equivalent to the introduction of a railroad to the district or to the establishment of a smelter in its vicinity. The matter is under consideration.

## Stamp Mill Capacity.

Written for the MINING AND SCIENTIFIC PRESS.

There is an undoubted tendency to endeavor to increase the duty of the quartz mill by various devices. In any mill of given capacity per stamp this capacity may usually be increased in a variety of ways, if not already at the maximum. The screen may be changed for one of coarser mesh, or the number of drops per minute may be increased, or some other scheme may be tried, such as crushing finer at the breakers. Of the several expedients here suggested the last is undoubtedly the best, but a change from any given screen to one of coarser mesh, while possibly increasing the tonnage passing through daily, may have the effect of producing a coarser pulp, which will not so readily yield up the values. With the tendency to increase capacity of the stamp battery is also the desire to crush finer than has been the practice heretofore. High capacity, with consequent low extraction, is not a condition to be desired. The duty of the stamp mill battery varies greatly, even in the same district. In some districts the main object appears to be capacity, and with it is usually found a higher grade of tailings than is commonly found as a result of gold milling operations. On the Rand, South Africa, it is more common to find the tonnage per stamp to exceed rather than fall below five tons daily. In California the average is probably between three and four tons per stamp, though in some localities in that State it is five tons or more, and at the Gold Hill mine, near Angels, in Calaveras county, at one time as high as seven tons per stamp were put through the battery. This ore consisted of a soft, decomposed greenstone schist, with enough quartz in the form of veinlets to help to give large capacity. Soft ores do not always yield large stamp tonnage, as, for instance, in the Calico silver district, in San Bernardino county, Cal.; the Silver Monument mine and some other mines in Garfield and Odesa canyon produced a soft ore—a rhyolite tuff impregnated with chloride of silver. When this ore was crushed in the stamp batteries alone it required a very large amount of water to secure a daily output of three tons per stamp, but when the brittle, though soft heavy spar ores, or the hard flinty jasperoid ores of the district were fed with the soft tuff, the daily capacity of the stamp at once was raised to more than five tons. The stamps in the Run-over mill weighed 900 to 1000 pounds and dropped 5 inches 110 times per minute. The ore did not require extremely fine crushing, as it was charged to pans where it was subjected to a certain amount of grinding during the process of amalgamation. The screens used were 600 to 900 meshes per square inch. At the Homestake mine, Lead City, S. D., the duty per stamp is about four tons per day, varying somewhat in the ores from the several mines of the group. The mesh of screen is important in the milling of ores, and this should be determined by the extraction of precious metals. Undoubtedly fine crushing renders the small particles of valuable mineral more easy of attack by either quicksilver or solutions introduced for the purpose of dissolving either the gold or silver. A particle of gold enclosed within a grain of quartz will probably be lost, as it is not exposed to the action of quicksilver, or to the dissolving influences of cyanide or other solutions. Neither is it in suitable condition for concentration. With coarse crushing, then, may usually be anticipated high-grade tailings. There is a desire to secure large stamp capacity while at the same time keeping tailings values down. How to accomplish this is a question for the mine superintendent or metallurgist in charge to determine.

Undoubtedly one method of accomplishing this is by crushing the rock finer at the breakers. The smaller the maximum of size as the ore comes from the breaker, the greater the capacity of the stamps within certain limitations. As a rule the rock breakers do not do as much work as should be required of them. In some mills the breakers are only run a few hours each day, and the maximum sizes of pieces of ore going to the batteries are often so large as to be unable to pass the lip of the feed slot at the back of the mortar. If the crusher be set to crush finer the capacity of the mill will at once be increased. If the ore coming to the mill gains upon the breaker man, then a different arrangement must be provided. Breakers set tandem, as suggested above, will increase capacity largely.

Where all the ore from the mine, after being run through a large breaker, which crushes it to pass, say a 3-inch ring, falls on a grizzly which sizes it roughly to 2 inches, the coarse product going to a smaller breaker for finer crushing, it will be found to accomplish a wonderful saving by increased capacity of the stamps. This is a feature of mill practice which many mill men seem slow to recognize. In a 40-stamp mill, where rock of uniform grade was fed to the stamps, several experiments were tried with screens of varying size and different heights of discharge. It was found that a 30-mesh screen, with a

6½-inch discharge, crushed four and one-quarter tons per twenty-four hours. An adjoining mortar, with a 40-screen and 3-inch discharge, crushed as nearly as could be estimated about the same amount of ore, but the tailings were about 10 to 15 cents lower than on the higher discharge battery. This indicated that the ore required the finer crushing to release the gold bound up in the quartz and pyrite. In a case like that cited it is wisdom to adopt the finer screen and low discharge, but in another mill on different ore similar experiments may not produce the same results. Each case should be given the advantage of experiment. The simple fact that each stamp in a mill is crushing four tons per twenty-four hours, and that 42% of the values are being saved, does not prove that by altering the running arrangements of the mill it will be impossible to secure better results by still finer crushing and at the same time keep up or increase capacity. An increase in mill capacity without increase in value of tailings means a lowering cost of milling.

Every mill man who takes the proper interest in his work is desirous of reaching in his mill the maximum of capacity with the minimum of loss, but it should be remembered that a method which is applied successfully with one kind of ore may not give as satisfactory results with another. The mill man is therefore required to experiment until he has reached as near perfection of the economic problem as seems possible under existing conditions.

Often the ore of a mine is of such character that large tonnage per stamp is impossible without heavy losses in the tailings. Some mills do not crush over 1½ to 2 tons per stamp, because the rock, while requiring fine crushing, is very hard and flinty and difficult to amalgamate. In such cases it is, doubtless, economy to reduce the capacity per stamp and save as high a percentage of values as possible. Increase in mill capacity may always be obtained by increasing the number of stamps. It is safe to say that in a large mill ore may be treated at a lower cost per ton than in a small one, for the reason that the ratio of expense per ton is less in a large mill than in a small one. The crew required to run a 5-stamp mill may also run one of ten stamps, and the crew of a 40-stamp mill may usually operate one of sixty stamps. Power generally costs less per unit; fewer men are required per unit; and the original capital expense per unit is less—the unit being either the stamp or the ton of ore crushed.

It has been suggested above that by crushing the ore finer at the breakers the capacity of the stamp battery may be materially increased. This has also been accomplished another way, and that is by conducting the pulp from the battery (which is provided with a coarse screen—60 to 150 meshes per square inch), to a rotary grinding mill, of which there are several types, in which the pulp is ground to the necessary fineness to pass a 900 to 1600 screen, or finer if necessary. This results in largely increased capacity, with somewhat increased expense for plant and power.

Still another method, and one which may be worked in conjunction with the tandem rock breakers, is that of placing a comparatively coarse screen in the battery (400 meshes to the square inch), which will give large initial capacity. It has been proven by many screen tests made in a great many mills, that no matter what the mesh of a screen may be, there is always a large percentage of the ore crushed which will pass a very much finer screen than that in the battery. This fact insures the prompt discharge of the finest material. If this pulp, as it comes from the battery, be run through a fine trommel, or on an impact screen supplied with the proper mesh to produce the desired fineness of pulp, say 1600 to 2500 mesh, the fine sand and slimes will pass through the screen and be taken care of for further treatment by amalgamation or cyanidation, while the oversize is sent, by automatic conveyor, back to the battery for finer crushing. This keeps a certain amount of pulp in circulation, but it results in high battery capacity and all of the ore is reduced to desired fineness with the least loss of time and expense of power. The feeder must be set so that it will not overfeed the stamps, or the battery screen will become clogged. Just to what extent the capacity per stamp may be increased cannot be determined offhand. This can only be ascertained by experiment. With different ores the result will differ more or less as it does in the ordinary methods of crushing. There are other important factors which influence the duty of the stamp mill. These are quantity of water fed in the battery; inclination of the battery screen; the superficial area of screen surface; the height of drop and number of drops of stamp per minute. The weight of stamp varies somewhat with the wearing down of the shoe, but this is in a measure equalized by the increasingly higher drop which results as the shoe wears away. Careful millmen keep the drop as nearly uniform as possible by adjusting tappets.

The introduction of double crushing, as suggested here, in no manner alters the other factors in securing high stamp duty and satisfactory amalgamation, or good results in cyaniding. Slimes are no longer so much to be dreaded by the millman and the cyanide operator. The introduction of proper classifying devices has made it possible to separate the sands from the slimes and to treat each separately.

## The Strength and Life of Mine Timbers.\*

Written by W. H. STORMS.

The problem of the support of underground workings of mines is an ever important one with the miner. In some instances the following data are secured from specific tests of various kinds of timber, where they have been placed in the same shaft, drift or stope, either in the same sets or in alternate sets, with a view to learning from actual experience what timber best met the requirements of the several cases.

These notes apply only to the Pacific coast, where only Pacific coast timbers are used. In other regions the timber, grown under somewhat different conditions, may be either better or worse for the purpose.

On the Pacific coast there are few hardwood trees which are suitable for use as mine timbers. In fact, oak is about the only wood, aside from the numerous conifers, used in these mines. There are a few rare exceptions, which may be mentioned more as matters of interest than of value, where cottonwood, ironwood, juniper, old railroad ties, and even yuccas, are used as mine supports; but these, for the most part, are on the desert, where the choice of timber is determined by environment. For that matter, the same may be said of almost any other locality where timber is available—the miner usually prefers that which is easiest to obtain, and which is the least expensive.

There are on the Pacific coast about sixty varieties of cone-bearing trees. Among these the most important are probably Oregon pine, spruce, yellow pine, sugar pine, pinon pine (bull pine), several varieties of fir and redwood. Perhaps the most commonly used of these several varieties of cone-bearing trees in California is the yellow pine, though all are agreed that the yellow pine is neither the strongest nor most durable. Farther north—in Oregon and Washington—the well known Oregon pine is largely in use, but there, as elsewhere, the matter of choice is determined usually by that which is most accessible and least expensive. Oregon pine is variously called "Douglas fir," "Douglas spruce," "yellow fir" or "red fir," according to its color, and by lumbermen and builders "Oregon pine," "Puget Sound pine," etc., but authorities have centered on "Douglas spruce" as the proper name for this magnificent timber.

Elaborate tests have been made with Pacific coast timbers, with a view to ascertaining their respective values for structural purposes. When the engineer desires to build a bridge, a head frame, or a building, he is enabled to figure on conditions which are nearly constant, but when mine workings are to be supported by timbers he can no longer depend upon constant pressure or strains resulting from the shifting of such weights. The outgrowth of this practice has been to increase the size of timbers in seeking additional factors for safety, until it is not an uncommon thing to see timbers 30 inches in diameter in drifts and stopes. But experience proves that even these great logs are insufficient to withstand the tremendous strains which come upon them, and engineers are arriving at the conclusion that it is more economical, and quite as safe, to use smaller timbers, and, where practicable, to fill the mine excavations with waste contemporaneously with extraction of ore, and that, while this method is more expensive in first cost, it is far superior and less expensive in the ultimate cost per ton of ore removed.

It has been observed many times that where drifts are timbered through very heavy ground the largest sized timbers last but little, if any, longer than those of considerably smaller dimensions. Where this is the case it is certainly less expensive to renew breaking timbers with sticks of moderate size than to have to replace very large ones with others equally large, in about the same length of time. This applies particularly to swelling ground. It has been repeatedly proven that by lagging the sides of a drift in swelling ground in such manner as to admit of cutting away of the material as fast as it forces its way through the open spaces between the lagging, and also relieving the lagging and the posts of the set by cutting out the rock as it is thrust forward, the set may be kept in position much longer than where tight lagging is put in, with a view to holding it back. The pressure is irresistible and cannot be held back—the ground must be relieved, and where this is promptly and properly done the life of the timbers, of whatever kind, will be greatly increased. Since this is the case with side lagging, why not adopt the same method for the back of the drift, and instead of lagging the roof of the drift as solidly as possible—the usual practice—leave broad open spaces between the lagging, that the back may be relieved in the same manner as the sides? Timbering is expensive, not only in first cost, but in framing, handling and putting in position, and in re-enforcing, but particularly in renewing, and any method of timbering which will have a tendency to prolong the life of the timbers will reduce the cost of timbering.

In stopes, as previously stated, it has been shown that smaller timbers will perform the functions de-

manded, or expected, of large ones, if filling is properly and promptly placed. It is a well-known fact that the heaviest timbers, no matter how placed, are an insufficient support to the tremendous crushing force of the hundreds of thousands of tons of rock which sometimes settles upon them, particularly when the weight shifts from one direction to another, as the excavation of large masses of ground proceeds above, below and on either side of a timbered stope. Filling, then, is imperative in a large mine, and as filling cannot be either dispensed with or neglected, smaller timbers will suffice to sustain the weight pending the filling of the excavation. By smaller timbers is meant those having 12 to 18-inch dimensions as compared with those of 24 to 30 inches.

In attempting this substitution of smaller for larger timbers, the method of filling is very important. If a stope 100x150 feet is superficial area, and standing at an angle above 45°, be carried up full size several sets above the floor of a level, and the entire stope, excepting gangways and mill holes, be filled to within two sets of the back, this stope is in great danger of collapse unless the walls be very firm and without a soft gouge, and there is equal danger if the ore body be at all heavy, even though the stope be timbered throughout with square sets. There are cases, of course, where this may be done, and done with impunity, but there are many more places where there would be grave danger in attempting it, and this danger is greatly increased in the case of ore bodies which grow narrower upward.

Hewn timber and peeled round timber are undoubtedly superior to the square sawn timbers, but hewn timbers are rarely used except for shaft work, where sawn timbers are not readily obtainable. The hewn timbers are stronger and less liable to split under stress than the sawn timbers. Timbers may be hewn with such exactness as to make them rival the sawn timbers, if care be taken. The finest job of hewn timbers for mine purposes I have ever seen is in a shaft on the Mount Pleasant mine, near Grizzly Flat, El Dorado county, Cal. There a two-compartment shaft has been timbered to a depth of 265 feet with hewn timbers about 12 or 14 inches square. The shaft has perfect alignment and the framing and facing of the timbers has been done with such care that at first glance I thought sawn timbers had been planed before placing them in position in the mine.

Round timbers are used to a great extent throughout California mines, except in shaft work, where square timbers are usually employed, and in most of the large modern shafts, either Oregon or Puget sound timber, the so-called "Oregon pine" is used. It is no uncommon thing, however, to see in the older shafts on the Mother Lode, round timbers hewn flat on two sides. This practice, however, has mostly disappeared.

As already stated, the kind of timber found in mines is that variety usually the most easily obtainable, and generally this is the least expensive also—at least in first cost. As to the strength of the timbers, less attention is, perhaps, given this, it being the aim of the mine superintendent to employ such timber as in his judgment will meet his requirements, and there is a predilection in favor of timbers of liberal size.

Even more important than the first cost of timbers and the placing of them in position in the mine, is the life of the timbers, for it is more expensive to remove old timbers and replace them with new, than the first cost, consequently it is desirable to have them last as long as possible.

There are many conditions which have an important influence on the life of timbers when placed underground in mine workings. Among those influences which are most noticeable are the condition of the mine atmosphere; its humidity and temperature; the absence or presence of water (not merely dampness or an occasional drip). All miners are aware that any kind of timber under water will last almost indefinitely; while that which is alternately wet and dry decays rapidly. A warm, moist atmosphere is more destructive of timber than a cool, dry one, for that matter. Heat has a particularly bad effect on timbers of any kind when placed underground.

The condition of the timber when it goes into the mine is very important. A thoroughly seasoned timber will outlast a green one or one but half seasoned, unless placed under a constant stream of water. Timber should be examined in the yard, and those sticks selected which show a firm, solid growth, whether the rings which represent the annual growth of the tree be close or some distance apart. Often, where the grain is coarse, the space between the rings is soft and spongy, and may be readily picked out. This timber will not endure, and should be used where filling will soon relieve it of weight. Timbers well seasoned, and with a firm, solid growth, will last best, and may be used in shafts, stations, drifts and other permanent openings.

The season of the year when timber is cut is important. That cut in winter is firmer and harder than that cut in the spring and summer months when the sap is up. It is also a fact that timber grown on the hillsides facing the south is superior to that grown on the north slopes, probably due to the fact that the north slopes are more moist, and the growth of timber more rapid, and consequently softer and less enduring.

(TO BE CONTINUED.)

\*Abstract Trans. Cal. Min. Assn.

## Formation of Ore Bodies on Intersections.\*

Written by MARK B. KERR.

Practical miners and mine owners generally are rather more interested in the commercial value of ore bodies than the form of the deposit or the possible cause of origin of the gold.

Gradually and surely, however, the physiography of a special region and the geology of the vein fissures coursing through it are being studied with more interest and precision. The intelligent direction of mine exploration must be based upon scientific and mathematical lines, else such development must necessarily become random and fortuitous. In many failures of the past had the geology been better understood, the elements of chance in the explorations would have been much lessened.

Recently many papers by eminent chemists and economic geologists have appeared in the proceedings of the American Institute of Mining Engineers by Posepny, Lindgren, Weed, Gillette and others on "Replacement," or changes in ore-bearing fissures and the rock contiguous thereto. New classifications and terms have been introduced to more systematically explain these matters, and metasomatic forms in ore-bearing fissure veins appear to be the theme of the present.

How were these changes effected? Was a given opening filled from below by solutions from ascending waters, or were these solutions, either hot or cold, spread laterally, thus filling the opening fissures and adjacent territory?

And further, after arguments have been made upon the merits of these theories, another question arises: What force or forces would be required to send up these waters, and if downwards, what energy would cause the surrounding cavities to be filled?

Thus another term of Greek origin is coined and "Osmosis," or the forcing of one chemical solution through another is now used to represent this pushing force.

Mine owners often say "what is the use of this contention and what difference does it make, anyway, which one of the theories is correct, we are interested more in the fact whether or not that certain deposit will pay a profit." Whilst without doubt, the commercial aspect is the most important consideration, still if the mine owner can once be made to see that without theory, the facts will never be discovered, he will soon realize that it is "money" to him to follow out development on scientific lines, and save the expense of misdirected exploration.

For the past ten years the writer has studied closely the gold-bearing veins of the Pacific slope, both in flat granite fissures as well as in the steeper slate veins of the Mother Lode, and has seen no reason to change the first opinion formed by him that the ascending waters carrying gold in solution were responsible for most of the gold deposition, and oxidation of the solutions by surface waters caused the richer depositions near the grass roots.

In this practical work, one particular feature was noted, viz.: that where intersections occurred, whether on separate veins or on joint or fracture planes, the ore body was larger and richer than elsewhere. This is not strange, for the most insoluble portions of a solution must be deposited where the flow is the freest and cooling most rapid, just as in a bend of a river, the largest deposits and greatest width of sediment and gravel will accumulate at the intersection of the courses of the stream. So, in following up the crevices or fracture planes in an ore body, the moment an intersection at the apex of the seams, or a cavity in a corresponding trough, is encountered, the ore body is enlarged, and what is more to the point, almost invariably enriched.

Consequently a rule can be put down, when the values in an ore body pinch in their strike, viz.: follow along a fracture plane until another parallel intersection is found, and this is likely to lead into "pay" again.

These joint and fracture planes are more readily discerned in the granite than in the slate veins, but can be readily found in the latter if looked for carefully. It is my opinion that gold has been deposited more on the trend and dip of the fracture planes in fissure veins, than on the trend and dip of the main formation. Following out this theory, we can mathematically project the general direction of an ore body and thus save a great deal of useless deadwork in those portions of the vein of grade too low in value to pay for mining and milling. In other words, the dip and strike of a pay shoot in my opinion (or the "rake" as it is sometimes called) can be obtained and projected with mathematical exactness, when the strike and dip of the transverse fracturing has been discovered. Too much attention has been paid by geologists, in my judgment, to general form and classification of ore bodies and not enough to exactness in strike and dip of the intersecting veins forming the mass.

It is my intention to bring before the members of the Miners' Association two instances, under my personal supervision, of the facts proving the theory, by practical illustration.

## MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

### ALASKA.

G. A. Singer, superintendent of the Olympic mines at Woodsky, expects to resume work.—The Leland Dredging Co. is building a dredger to operate on Solomon river, in the Bonanza mining district, Seward peninsula.—At the Humboldt mine in Silver Bow basin, near Juneau, ten stamps are dropping.

A. H. Brooks, geologist in charge of the division of Alaskan Mineral Resources of the United States Geological Survey, plans work in Seward Peninsula, the Yukon-Tanana region, Prince William Sound, Matanuska and Controller Bay coal field, the Yakutat Bay coal field, and southeastern Alaska for season 1905. F. H. Moffit and P. L. Hess will study the Nome region, which was topographically surveyed last year by T. G. Gerdine. Special attention will be given to the high bench gravels, and an effort will be made to determine the old topography which they represent. They will also make further study of the tin deposits near York. The Solomon River region is to be mapped by T. G. Gerdine and assistants. D. C. Witherspoon will continue the topographic survey of Yukon-Tanana region, beginning at Circle on the Yukon and proceeding west toward Fort Hamlin. L. M. Prindle will proceed from Dawson westward to Fairbanks on the Tanana to map the areal geology and to study the placer deposits. U. S. Grant, of Northwestern University, will study the copper deposits about Prince William Sound and make stratigraphic studies along the shore line of the Sound. S. Paige, geologic aid, will make a geological reconnaissance of the Herendeen Bay coal field in Alaska Peninsula. An accurate topographic map on the scale of 1 mile to the inch will be made of the entire coal region about Controller Bay and of the area within which there is indication of petroleum. G. C. Martin, A. G. Maddren, E. G. Hamilton and W. R. Hill will do the work. R. S. Tarr will make a reconnaissance survey of the Yakutat Bay region. It is desired that he should determine whether the coals reported to occur in this district belong to the same horizon as do those of high grade found in the Controller Bay region, 100 miles to the west. F. E. Wright and C. W. Wright will continue to map the general geology and to study the ore deposits in southeastern Alaska, including the study of the gold and copper deposits of Admiralty island.

### ARIZONA.

#### Cochise County.

(Special Correspondence).—The report of the Calumet & Arizona at Bisbee shows that the company produced during 1904, 15,819 tons of refined copper. The production in gold was \$195,926.18, averaging \$12.38 per ton of refined copper. The average price received for refined copper was 12½ cents. Dividends paid out amount to \$1,300,000.

Bisbee, April 11.

Superintendent Whitson of the Quincy-Bisbee M. & D. Co., 5 miles north of Naco, intends to commence sinking a three-compartment shaft.

W. F. Staunton, superintendent of the Tombstone Con. mines, at Tombstone, says water has been drained out to the 800-foot level, and crosscuts are now being run on that level. At 700 feet the ground was equally as wet as it was at the 800-foot level, but now it is dry. They are going deeper, and draining the basin as they go. They are raising 3,150,000 gallons of water per day, and he expects to place an additional pump on the eighth level, which will facilitate operations. In the Silver Thread shaft a fine ore body has been opened up 100 feet below the former water level, and ore is being shipped regularly.

#### Gila County.

(Special Correspondence).—The Globe & Arizona Dev. Co. has started development work on three claims near Globe. The Great Eastern shaft is down 85 feet.

Globe, April 11.

It is reported that a St. Louis, Mo., company has been formed to work the Keystone, near Globe, with J. C. Erman as superintendent and J. R. Finletter as general manager.—Superintendent J. B. Coplen of the Inspiration M. Co., near Globe, reports that the Woodson tunnel is in 680 feet.—T. G. Cockrill, president of the Pinto Creek M. & S. Co.; G. Watkins secretary, and J. W. Castle treasurer, all of St. Joe, Mo., recently examined the company's property on Pinto creek, near Globe.—The 350-foot level of the Yo Tamhien mine has high-grade ore. The lower crosscut tunnel, which Superintendent Fuller is driving with power drills, is in 730 feet.

#### Graham County.

(Special Correspondence).—The strike at the Copper Creek mine, near Klondike, via Wilcox, in a recent test at the El Paso Smelting Works, gave high returns. The company has completed a road for ore hauling and has put in a double-cylinder gasoline hoist, and they will put in an air compressor and machine drills. T. Gill has charge of work. The ores will be treated in El Paso until the company can build a 100-ton smelter.

Klondike, April 10.

(Special Correspondence).—The output of copper for March was low, because of washouts on the Coronado railroad carrying ore from the mines of the Arizona Copper Co. and the Shannon mines to the smelters in Clifton. The A. C. Co. produced in March 1228 tons and the Shannon Co. 480 tons of copper.—The Irish M. Co. has cut a 7-foot vein of good copper ore in its tunnel on the east side of Chase creek, near Clifton.—The Coronado Copper M. Co. is developing its properties near Metcalf.—The New England & Clifton Copper Co. will commence shipping ore as soon as their hines are completed.—The last shipment of ore made to El Paso,

Tex., by Superintendent R. Lakeman from his mine on Gold gulch netted \$178 per ton.

Clifton, April 11.

(Special Correspondence).—The Shannon Copper Co. at Clifton is setting up a new 250 H. P. engine to give additional power to run the two furnaces continuously. The development of the mine has increased its output to the point where it can supply two furnaces.

Clifton, April 11.

A good strike has been made in the Irish Co.'s mines on the east side of Chase creek, near Clifton, by Geo. Truesdell.

#### Maricopa County.

(Special Correspondence).—In the Wickenburg section several properties are rapidly approaching the productive stage. The property of the Oro Grande M. Co., 4½ miles north of Wickenburg, has been opened up by 6000 feet of development. The main shaft is down 340 feet. The company's 10-stamp mill, which has a capacity of fifty tons a day, is steadily at work. The ore here is free milling.—At the White Gold M. Co. excavating is completed for the new 20-stamp mill, which is being hauled in from Congress Junction. The bad weather has delayed the erection of the mill sixty days. An additional twenty stamps will be added. This property is 12 miles northeast of Wickenburg on the Hassayampa river. The development consists of 2000 feet.

Wickenburg, April 11.

#### Mohave County.

The 10-stamp mill of the Blue Ridge G. M. Co. in the San Francisco district, east of Vivian, has 1050-pound stamps with 6-inch drop, 110 to the minute. The mortars are set on concrete foundations, placed on bedrock. The mine is opened 150 feet, with sump of 20 feet, from which the water for the mill is pumped. At the 150 level the ledge has been drifted upon for 180 feet. W. Fellows is superintendent of the mine and mill.—The German-American Co. at Acme will put in a 10-stamp mill and 30-ton cyanide plant at the Treadwell mine and build a 75-ton ore bin and 40-foot gallow frame.—A new hoist, gallow frame and ore bin have been ordered for the 35th Parallel mine.

A crosscut from the bottom of the 175 level of the Vanderbilt mine, at Cerbat, has entered a 4-foot vein of good ore. The property is being worked by the Cerbat Mountain M. Co., R. C. Walker superintendent.

The Chloride G. M. Co., working the Samoan mine at Chlor de, has shipped to the Selby Smelting Works at San Francisco, Cal., five carloads of ore. L. Hoffman is superintendent.

#### Yavapai County.

(Special Correspondence).—Good copper ore is reported in the properties of the Wisconsin & Arizona M. Co. in the Turkey Creek district.—The Bannie mine, in the Walker district, has been sold to Linsey, Evans & Ingalls of New York City. Sinking has been started on a 400-foot shaft. A reduction plant will be built on the property.—The Pine Mountain claims, near Walker, have been purchased by E. F. Bacon of Detroit, Mich. He also has acquired a group of four claims near the Sun Dance mines on the Hassayampa, on which work is to begin within a few weeks.—The miners at Jerome in convention have refused to join the boiler makers' strike instituted in the United Verde. So the general walk-out that was predicted will not take place. The recent accident at that mine was thought likely to add further to the miners' grievance, but it has not done so, they evidently appreciating that the accident was not the fault of the management.

Prescott, April 11.

E. S. Campbell, general manager of the Richinbar M. Co. at Richinbar, is preparing to start up the 10-stamp mill at the mine and to increase its capacity.—F. Barr, of the Thumb Butte M. Co., west of Prescott, has completed retimbering a tunnel, which was caved by floods.—G. U. Young is building a quartz mill in the Thumb Butte section.—The foundation for the new Val Verde smelter has been started.—It is reported that H. M. Merriweather of Kansas City will start work on the Geo. Zika properties, near Richinbar. E. S. Campbell has charge.—H. W. Campbell, H. Miller and O. F. Bacon of Chicago and Detroit, have purchased the Pine Mountain mine and 10-stamp mill, near Walker, and will work the property. The main shaft is down 400 feet.

Superintendent Tharsig of the Lincoln gold mine, near Crown King, intends to have the concentrators in and the mill running by May 1.

J. Larson has commenced work on the property of the Venture Hill M. Co. near Jerome.

It is reported that the Rincon M. Co., near Martinez, will put in a new hoisting plant with a capacity of 2000 feet. A milling and cyanide plant have been ordered and will be built by T. Stewart. The work is being done mostly on the Dixie ledge. G. D. E. Mortimer is superintendent.—D. J. Sayer of the Sayer G. M. Co., which has taken over the Churchill group, near Martinez, is expected to arrive from Denver, Colo., to continue work. The shaft is down 420 feet.

#### Yuma County.

At Columbia mining camp Wm. Bear is sinking a 100-foot shaft.—The Eureka at Columbia, belonging to J. W. Lind, is preparing to ship ore to the smelter.

## CALIFORNIA.

#### Butte County.

Platinum has been found near Chico, Magalia and Oroville, that near Chico having a value of \$5.46 per ton of concentrated sands and worth 8 cents for each dollar in gold. E. W. Abbey of Honcut is preparing to prospect gravel deposits between Oroville and Honcut that he has bonded. Dredgers will be built if the ground be rich enough.

#### Calaveras County.

The Melones Co., at Robinson's Ferry, will add forty more stamps to their mill and will have 100 stamps dropping inside of three months. A new air compressor is to be put in. The company is shipping twenty-five carloads of sulphurets per month to Selby Smelting Works.—The new tramway of the Utica Co., at Angels, ex-

tending to the railroad station, has been started.—The Fortuna M. Co. has purchased the Paul Lane mine at Altaville.—The 10-stamp mill on D. Roller's mine at Carson has started operation.—Work has been resumed at the Eazy Bird quartz mine near Mokelumne Hill, under the superintendency of W. T. Robinson.

#### El Dorado County.

It is reported that the ledge of the Rio Vista copper mine, near Fairplay, has been cut 400 feet below the surface. F. H. Harvey is general manager. The company will drift north and south on the ledge and make arrangements for a smelter.—Work has been started on the Rebel Hill mine, near Georgetown, to put it in shape to be hydraulicked.—The 2-stamp mill at the Hanson mine, near Georgetown, has been started and work is being pushed on the mine.

#### Kern County.

At the Yellow Aster mine at Randsburg a new motor engine has been put in to be used instead of the mules for hauling ore cars to the mill. It is a double ender of 15 H. P. capacity, weighs 6200 pounds, and is capable of hauling 30 cars. A third rail will be laid for the present and the same cars used as now.

#### Nevada County.

H. Kaler has resumed work at the Lindsay mine, near Maybert.

It is reported that a 10-stamp mill will be put in at the Chicago mine, near Grass Valley. A double shift is driving south on a new ledge.—The Murchie mine, near Nevada City, is to have a new 10-stamp mill with 1400-pound stamps.—The Morning Star mine at Badger Hill, near Nevada City, is being worked by Philip Deidesheimer. The shaft is down 50 feet and a hoisting plant is to be put in.

It is reported that the Polar Star mine, near Grass Valley, will resume operations. J. W. Neil is manager. The owners of the Scott's Flat gravel diggings on Deer creek, 7 miles above Nevada City, are planning to sink a shaft for the blue gravel channel that is supposed to underlie that section of country in its course from Blue Tent to Hunt's Hill and Red Dog. They expect to have to sink 400 feet.

#### Placer County.

H. T. Power, superintendent of the Hidden Treasure mine, at Bullion, reports that the 10-inch bore hole is down 100 feet. The shaft is 210 feet deep and the upraise 310 feet. When the boring is finished it will let the water out of the shaft into the tunnel, and the bore will then be enlarged to the size of the shaft. The tunnel is now about 2 miles long.—It is reported that the Buckeye mine, near Forest Hill, has shut down.

#### Plumas County.

The Tabor mine, near Gibsonville, is working with thirteen men pushing the main drift. The indications are favorable for breaking into the channel. C. D. Acker is manager.—A. W. Whitney has sold his mining property on Rush creek, formerly known as the Providence Hill mine, to the Rush Creek G. M. Co., who will put it in order. The dam at the head of Rush creek will be completed.—In the Nelson mine, near Willow Ranch, the company is running a bedrock tunnel. The managers of the work are Wilson and Tyler.—G. Maurer has a crew raising the breast of the restraining dam at the Bell mine, Elizabethtown. The mining property is under bond of sale to a Seattle syndicate, and under superintendence of H. K. Kling.—The Gibsonville M. & Dev. Co. is working at the Union mine, near Gibsonville, under the management of G. W. Lambert.

#### Shasta County.

In the Sunny Hill mining district, near Ono, the Marina Marsicano M. Co., L. F. Barlow manager, is putting in a concentrating plant and a 1400-foot aerial tramway. The new 5-stamp mill is nearly completed. The company intends to put in a cyanide plant.

#### Siskiyou County.

J. Beatbam, manager of the Lappin mine, Deadwood, has purchased an air compressor for the mine.—W. F. Klein is working his claim on Eddy's gulch, near Sawyer's Bar.—The Bill Burns claim, near Sawyer's Bar, under the supervision of G. A. Mohr, is keeping a crew employed.

#### Sonoma County.

The African Gold Reef M. Co. of Petaluma is working 14 miles from Santa Rosa and 1½ mile east from Beltaine. J. Henderson is president and S. A. Fancher secretary and treasurer, at Petaluma.

#### Trinity County.

C. M. Butler and Geo. Grotenfend of Redding have leased the Altoona quicksilver mine, at Cinnabar, and will begin prospecting. A Swedish company has leased the dump and is ready to start the smelter at the mine. The plant has a twenty-five-ton capacity.—At the Brown Bear mine, at Deadwood, the mill is crushing ore for sixteen leasers.—At the Lappin mine, at Deadwood, the air compressor has been put in and the lower tunnel is being driven in. When the connection is made, the force will be increased.—At the Frick & Davis mine on Donnelly gulch, near Deadwood, J. H. Covode, the owner, is putting in machinery to sink on the ledge.

#### Tulare County.

(Special Correspondence).—W. G. Anderson is putting in heavier hoisting machinery preparatory to sinking the shaft on the Redfield mine at White River to a greater depth. The mine is on Bald mountain, 2 miles from White River; the vein is 4 feet wide with granite walls, formerly known as the Last Chance mine. White River, April 10.

#### Tuolumne County.

The Clio mine, near Jacksonville, has been bonded to H. Malmgren of Los Angeles, Cal., for \$55,000.—J. Charters of Tuolumne has secured a six months' working bond on the Hope mine, near Columbia.—The Davis claim near Sugar Pine has been bonded to Los Angeles, Cal., people and it is said that a 5-stamp mill

will be put up. Allen has charge.—The shaft of the New Tonopah, near Columbia, is down 110 feet.—The shaft at the Hardtimes at Arrastraville is down 150 feet and will be continued until the 180-foot mark has been passed. W. P. Cunningham, president of the Bluebell M. Co., has been at the mine.—Superintendent R. B. Stanford of the Ranch mine, near Columbia, reports a large crew of men employed, the mill running steadily and the gravel high grade.

### COLORADO.

(Special Correspondence).—J. H. Richards of Boise, Idaho, president of the American Mining Congress, delivered an address before the Chamber of Commerce in Denver on the American Mining Congress, its aims and needs. He urged upon the people of this State and city the need of a suitable building where the congress could have its headquarters and its members could be made to feel at home. The building would also be used for the display of a large mineral exhibit.—The report that the students of the School of Mines at Golden, Colo., are contemplating a revolt against the management on account of the suggested addition of a secondary course for the benefit of mine and mill foremen does not seem to be well founded. Dr. Alderson, president of the school, has been censured for allowing his name to appear in a prospectus "Mining as a Business." It is not anticipated that the outcome will be serious. A movement is on foot to have the president investigated by the board of trustees on account of his alleged association with a mining company.

Denver, April 11.

#### Clear Creek County.

The Saratoga vein has been cut in the breast of the Newhouse tunnel at Idaho Springs 15,156 feet from the portal. The pitch of the vein and its course and position are as expected by the engineers. The character of the ore is identical with that found in the west level of the Saratoga. The Saratoga group consists of nineteen patented mining claims, covering an area of seventy-five acres, and 1 mile of the Saratoga vein. There is 47,000 feet of underground workings, two-thirds of which is now under water, and will be drained through the Newhouse tunnel. Three shafts are sunk on the vein, No. 1 being 400 feet; No. 2, 1000 feet; and No. 3, 600 feet in depth. Each shaft has a complete equipment of machinery and all are connected by levels. The vein in different parts of the mine is from 6 to 20 feet in width. The Saratoga group is held under bond and lease by C. Morgan and J. Owen of Idaho Springs, who will make connections with the mine workings, and as fast as the water lowers in the Saratoga shaft men will be put to work getting the mine in shape for production. Surveys show that the heading of the Newhouse tunnel is 265 feet below the bottom of the Saratoga shaft, and a level driven east 525 feet and an upraise of 365 feet will make connection with the ninth level 1525 feet west of the Saratoga shaft. The tenth level west from the Saratoga shaft has been extended but 720 feet, and it would require over 100 feet farther of driving and an upraise of 265 feet to make connection with that level from the Newhouse tunnel level. The Newhouse tunnel was located by S. Newhouse on February 13, 1901, the preliminary surveys being made in the spring of that year. But little work was done until the fall of 1903, and in the following January a power plant was installed at the tunnel mouth and it has since been driven with machine drills. For two and one-half years the tunnel was driven 9 feet in height and 10 feet in width, with double tracks laid with 35-pound rails, 18 inch gauge. In the center underneath the tracks is a waterway 14 inches deep and 2 feet in width, over which is laid a 19-inch exhaust ventilating pipe. The size of the tunnel was reduced to 6 feet in width and 7½ feet in height when the work was resumed the last time, with one track, this being deemed of sufficient size until the traffic through the tunnel would warrant its being widened. The maximum vertical depth attained by the tunnel is 1780 feet, equivalent to 2200 feet on the prevailing dip of the vein. The tunnel is owned principally by Englishmen, the corporation being known as the Newhouse Tunnel Co. of London, the Colorado corporation being known as the Argo Mining, Drainage, Transportation & Tunnel Co. The projected terminal of the tunnel is under Quartz hill, which will be reached in about 7000 feet of driving. The tunnel, including equipment, has cost to date \$400,000. The breaking cost has been about \$19.67 per foot for the double track section and less for the single track portion. The grade of the tunnel is 5 inches per 100 feet.

#### Custer County.

(Special Correspondence).—The foundation for the 300-ton cyanide plant between Silver Cliff and West Cliff is nearly completed and the lumber for the building proper has commenced to arrive. It will probably be six months before this mill is in operation. C. M. Fueller of Denver has the contract for building the mill. Silver Cliff, April 9.

The Hector mine, in the Hardscrabble district, near Custer, has started up. This property has been idle for some time on account of contending interests.

#### Dolores County.

The Durango Leasing Co. has resumed operations on the Enterprise mine, near Rico, with twenty men. T. Rockwood is manager. J. S. Krantz is in charge of the mine and C. W. Blackburn of Cortez is in charge of the mill.

#### Gilpin County.

During March the shipments of smelting and crude ores, mill tailings and concentrates from the Black Hawk depot to the Denver and Golden smelters amounted to 359 cars, or 7525 tons, which shows an increase of 60% over the corresponding month for 1904.—G. L. Baughman of Rollinsville has bought an interest in the Happy Hollow claims between Rollinsville and Gambell gulch. Surface work has been commenced to open up the vein, after which sinking will be started.—The Jumbo Mountain M. Co. on Jumbo mountain, on Jenny Lind gulch, near Boulder Park, have driven a crosscut tunnel 300 feet through Jumbo mountain to cut their veins.

A. E. Simpson is superintendent.—The Colorado and the C. & H. claims, on the east side of Gambell gulch, have been leased and bonded to F. Augustus of Rollinsville and L. Sarchalett of Perigo.—Sinking has been stopped at the After Supper mine of the Banzai M. Co. at Black Hawk, reports Superintendent A. Watters. A lift of 110 feet has been sunk, bringing the shaft down to a depth of 250 feet. Drifts have been started off on both sides of the shaft at a depth of 240 feet. L. R. Tatum of Denver is president and manager.

#### Gunnison County.

The Buckeye Chief and Bonanza Queen mines, near Pitkin, operated by Linn, Langill and Smith, have a tunnel in 200 feet. A winze is being sunk from the tunnel level, 120 feet from the portal, and is down 40 feet. The pay ore is being sacked for shipment.—A vein of good milling ore 18 inches wide has been struck in the Gold Links tunnel, at Pitkin, 1190 feet from the entrance. J. F. Pearson is superintendent.—The Golden Islet M. & M. Co. has leased the Jersey Blue mill on Ohio creek, near Pitkin, to treat the low-grade ore from the Cortland.—The management of the Chloride mine, at Pitkin, expects to unwater the lower levels.

#### Hinsdale County.

L. Kafka has contracted with J. A. Hunt and C. A. Weirs to build a new dam at the Hidden Treasure mine near Lake City.—W. J. Gardner of Paterson, N. J., and B. N. Ramsey have been examining the U. P. claims in Alpine gulch, near Lake City.

#### Lake County.

At Leadville the main drift from the Murphy shaft is in 60 feet.—At the Dome prospecting is still carried on from the bottom of the shaft, but as yet the ore channel has not been found.—Work has been started on the Sullivan shaft and the Lucky Joe shaft.—At the Nil Desperandum the new water column has been completed and raising water has been commenced. When the bottom of the shaft is reached the balance—15 feet—will be sunk, and then the drift to the south to catch the ore bodies will be started.—The Parson claim on lower Rock hill is now known as the Algot Mining & Investment Co. of London, England. J. Walsh is sinking the shaft the first 1000 feet.—The old shaft on the Myrtle claim, Iowa gulch, Leadville, has been cleaned out by D. Vaughn to a depth of 75 feet. A new plant of machinery is being put in and when this is completed the shaft will be sunk to a depth of 400 feet.

#### Ouray County.

It is reported that the Security G. M. Co. of Cow creek, near Ouray, will build a 40-stamp mill near the mouth of Cobb gulch.

#### Park County.

G. W. Chance of Philadelphia has purchased the Copper Verde claims in the Copper Gold district.

#### San Juan County.

The San Juan S. & R. Co. at Silverton expects to start up its smelter on June 1. The smelter, in addition to treating the ores of the Henrietta and Lizzie mines, belonging to the company, will buy custom ores.

#### San Miguel County.

The Japan Mines Co., at Telluride, have been driving an upraise from the tunnel level to connect with the upper workings of the Japan, which are filled to a depth of 250 feet with water, which, with the breaking through of the upraise, will be drained by the 500-foot shaft into the tunnel level, thence out 3000 feet into Savage creek. Engineer Comstock estimates that the old workings carry 3,000,000 gallons of water. To prevent accident a small drill hole has been kept 15 feet ahead of the blasts, so that there will be no mistake in breaking through and releasing this volume of water.

It is reported the Alta mine and mill at Telluride has resumed work after a short shut-down due to the breaking of the bullwheel on the tramway.—A. C. Kirby mill foreman of the 80-stamp Liberty Bell mill above Telluride, has started thirty of the stamps. The mill has been idle since last December, and in that time an entirely new process has been put in for the treatment of the ore, and the interior of the mill has been rebuilt.

#### Summit County.

The hull of the gold dredging boat of the Reliance Gold Dredging Co. is ready for the machinery, which has been shipped from New Jersey. The boat is in the French gulch, 1 mile from Breckenridge.—The Mekka Gold Mines Co., in which the Lennox gold mines syndicate of Colorado Springs is interested, will resume driving the bedrock drain sluice near Breckenridge, as soon as the weather permits, and will also work its rich ground with hydraulic elevator and "giants" during the entire season.

#### Teller County.

(Special Correspondence).—J. M. Jordan, secretary El Paso Con. G. M. Co., says that there have been no new developments in the drainage tunnel for Cripple Creek. If the Portland G. M. Co. does not subscribe largely it is likely that the Elktion will start and drive the present tunnel into their own (Elktion) ground. The El Paso has started sinking their shaft to the 1000-foot level, and, if the new tunnel goes through, they will sink to the 1400-foot or the new tunnel level. If the new tunnel does not go through, the El Paso will put in their big pumps, which they have on hand and have never used, and pump the water from the 1000-foot level. Cripple Creek, April 10.

The new shaft on the Mary Nevin, in the gulch between Beacon and Rosebud hills, Cripple Creek, is down 205 feet and will be continued for another lift of 100 feet under a contract issued by C. G. Jackson. A No. 5 pump and a 4-drill compressor have been put in. When the 300-foot point is reached, a lateral will be driven 155 feet north, where it is calculated an extension of the C. K. & N. vein will be encountered.—On the Black Jack lode of the Anchor Co., south of the Mary Nevin, the shaft is down 150 feet.—In the Fountain Valley claim of the Banner G. M. Co., Crowder and associates, lessees, are crosscutting at a depth of 330 feet, where sinking was recently suspended.—The 200-foot level has been

reached in the Rocky Mountain lode, below the El Paso Con., by H. L. Shepherd and associates, lessees, who intend to crosscut east into Beacon hill.

The Jefferson claim, on Battle mountain, Cripple Creek, has been leased to W. H. Camp of Colorado Springs, who will commence operations at the 500-foot bottom level and work north towards the Strong mine.

The Fortuna G. M. Co. has been formed by C. S. King, president; L. Mueller, vice-president, and C. A. Jacobs, secretary-treasurer, to work property near Battle mountain, Cripple Creek. The property consists of a shaft 500 feet deep, with a fine plant of machinery. L. Mueller has charge.—The J. A. Logan compressor is running to supply air to lessees of the Orpha May, at Cripple Creek.

## IDAHO.

### Boise County.

G. Z. Edwards, superintendent of the Lincoln M. Co., near Pearl, will contract for structural materials for the new cyanide plant. The new shaft is down 300 feet and will be continued until down 800 feet. The concentrator has been hung up indefinitely. The mill of the Kentucky Co., near Pearl, is crushing ore. The ores of this district are granular altered granitic gangue and quartz impregnated with lead and zinc sulphides; the gold values in milling ores range from \$5 to \$15 per ton, 25% free milling.

C. C. Gilliland of St. Louis, Mo., agent of the American Exploration Co., which owns the Nellie claims at Horseshoe Bend, and E. Nelson of Vermont, Ill., and C. W. Samuels of Clinton, Ill., have been examining the property and as a result Manager M. E. Hopkins has let a contract to drive the lower tunnel, which is in 100 feet, until it taps the vein. The property is to be equipped with electric power for drills. Tests are to be made on the ore preparatory to putting in a 100-ton cyanide plant.

### Custer County.

At Loon creek, near Custer, the Lost Packer Co. is completing 7 miles of the Jordan creek and Loon creek wagon road and grading and building the 100-ton smelter under the management of J. A. Czizek.

### Elmore County.

W. Oebs, president of the Gold Eagle M. Co., owning the Gold Eagle mine, in the Neal district, 35 miles from Boise, reports that the company is operating its 50-ton Chilean mill.

### Idaho County.

Jos. Coverly, superintendent of the Elk City M. & M. Co., says that the company will put in a 50-ton cyaniding plant this spring. The development so far has been by one tunnel and a number of open cuts. The main ledge is 8 feet wide.—The American Eagle near Elk City has arranged to resume work.

On Grouse creek, near Resort, the Gott M. Co. plans to make an 11-mile canal to carry the waters of Secesh creek to their gravel beds. They have four giants ready to use. The company will employ 100 men. J. J. Toler is interested.—Near Secesh, W. Allen and C. Wain have a 300-foot tunnel on their property on the south side of War Eagle mountain.

The Buster claims, 1/2 mile from Elk City, belong to S. W. Smith of San Francisco, Cal. The lower drift has been driven 500 feet on the vein and crosscuts will be driven. The ore is reported high grade.

### Kootenai County.

(Special Correspondence).—The Big Blackfoot M. Co., a branch of the Amalgamated Copper Co., is preparing to build a mill at Sandpoint.

Sandpoint, April 10.

### Shoshone County.

T. L. Greenough and P. Larson, owners of the Morning mine at Wallace, have filed an amended tunnel location of the long tunnel they are driving on their property, as it is to bear to the right on a 5° curve. When completed, the total length is to be 10,000 feet, of which 6000 feet have been finished. It is 8 feet high and 7 feet wide in the clear. It is being driven "for the development of the Morning, Evening and other lode mining claims, and for the discovery of other veins, lodes and mines in course thereof. This is the second longest tunnel in the Cœur d'Alenes, the Kellogg tunnel of the Bunker Hill & Sullivan, which is over 2 miles in length, being the longest.

The Oom Paul M. Co. near Wallace will resume work which has been stopped since November, and will put in a small electric hoist. The drift from the crosscut tunnel of the North Franklin near Mullan is in 148 feet. Machine drills are to be put in.—The Springfield Copper M. Co. is running a 1400-foot crosscut tunnel in the Stevens Peak district near Wallace. Walter Graham is president and E. Zeitfuchs, secretary and treasurer.—The Rex, or Sixteen-to-One, at Nine Mile is employing men in the mine and mill. The mine is equipped with an electrically operated 8-drill compressor, a Finlayson tramway, 6000 feet long, between the mine and the mill and a 300-ton concentrator. The mill operated by water power and is on the Nine Mile branch of the Northern Pacific railroad. The principal work in the mine this summer will be done around the No. 2 level which was run partly as a crosscut and later as a drift. It was in 1800 feet before the ore body was struck. J. P. Keane is superintendent.

## KENTUCKY.

A report of the U. S. Geological Survey on the lead, zinc and fluorspar deposits of western Kentucky states that it is separate from the Mississippi valley fields and differs from them chiefly in the presence of basic igneous dikes, in the abundance of fluorite and its almost constant association with the lead and zinc ores, and in the mode of occurrence of the ores, which are found principally in true fissure veins which have resulted from fracturing and subsequent faulting. In the other districts the lead and zinc are of primary importance, while in this region the igneous dikes and the fluorite are the primary or predominant features and the lead and zinc are only incidental. The minerals forming the ore deposits and associated with them in this district are

galena, cerussite, pyromorphite, sulphur, sphalerite, smithsonite, hydrozincite, calamine, greenockite, chalcopryite, malachite, fluorite, barite, calcite, quartz, kaolinite and ankerite. In addition to these, small quantities of some of the hydrocarbon compounds are occasionally found in the veins. Of all these minerals, only fluorite, barite, galena, sphalerite and smithsonite are known to be of economic importance within the district. The ore deposits thus far developed are somewhat unevenly distributed through Crittenden, Livingston and Caldwell counties. At the present time, as in the past history of mining in this region, the mines of Crittenden county include not only the largest producers in the district, but the largest number of productive veins as well. The successful development of the district is primarily dependent on the fluorite, as in the majority of the veins the lead and zinc ores can be considered only as by-products, and in many cases perhaps as mere impurities in the fluorite. Most of the mines are as yet in the oxidized zone, and much of the ore from this belt must be cleaned before shipping. With depth, however, the veins will become better defined and the ores cleaner. Further development along the veins now mined will undoubtedly be advantageous. Better transportation and shipping facilities will help to increase the output of the district.

## MISSOURI.

### Jasper County.

(Special Correspondence).—The Smith-Kernohan Co., of Cleveland, Ohio, has purchased a ten-acre mining tract at Prosperity. One shaft has been sunk 205 feet, and a run of sheet ore has opened up. The new company will build a large mill.—A large pump and other machinery are being put in at the Homestake mine at Granby. Work at the Homestake has been idle since Christmas, but will be reopened as soon as the mine is drained.—A. Wilson, of Joplin, has opened up a lead prospect 4 miles east of Joplin, making 15,000 pounds of lead per week; he is making arrangements to build a mill.—The Progress M. Co. have struck good ore at a depth of 200 feet on their lease on the Colclasure land, 5 miles east of Joplin. As soon as sufficient development work has been done the company will build a modern mill.—G. H. Glade, of Joplin, who has a lease on forty acres of mineral land near Spring City, is developing the tract; 1000 feet of drilling will be done this spring.—The J. A. C. M. Co., of Joplin, operating on the Robertson land, 3 miles southeast of Joplin, is preparing to sink two shafts on the land, because of rich showing made by drilling.—Gundling & Tobias, of Joplin, have a new mill on the Leonard land in the Chitwood district.—Ball, Gunning & Co., of Webb City, has let a contract for a concentrating mill on their lease on the Reliance M. Co.'s tract at Neck City.

Joplin, April 9.

## MONTANA.

### Fergus County.

J. L. Stuart of Lewistown reports a strike of high-grade galena 2 miles from Maiden.

### Flathead County.

J. M. Wolfe and party of Seattle, Wash., have been at Libby testing the placer ground owned by the Cherry Creek Placer M. Co. on Cherry creek, to ascertain what the ground will produce, and if satisfactory, they will put in a hydraulic plant.

The July mine, near Troy, is working two shifts. The steam hoist put in is in active use and the management will continue sinking indefinitely. The Big 8 mine, near Troy, which has been leased to Spokane people, is expected to start operations with an 8-drill compressor and mill.

### Madison County.

Preparations are being made by the Watseca Co., at Rochester, to resume operations on the tailings of the new mill.—Jones & Co. are taking out good ore from the New mine, near Rochester, which they are working under lease.—White and Thomas are shipping two carloads monthly from the Watseca to Helena.—It is reported that the Strawberry mill, near Pony, will be increased by ten more stamps, making it a 20-stamp mill. The ten stamps are crushing ore from the Clipper mine on Mineral hill.—Work is being rushed on the 20-stamp mill of the Garnet G. M. Co., at Pony. The ditch is being freed from snow and ice, and as soon as the water can be brought around to the mill it will be started.—Geo. Lennstrend and F. L. Buck have struck free milling gold near Pony adjoining the Atlantic and Pacific property, and may have a mill in operation on the property by July.

### Missoula County.

H. T. Wilkinson of Missoula contracted with O. Erickson to run a tunnel 50 feet farther in the Cape Nome claim, near Clinton. The tunnel on the Cape Nome claim is 658 feet long.

### Silver Bow County.

(Special Correspondence).—It is probable that the North Butte M. Co. will take over the Speculator, Jesse and other mines of the Speculator M. Co. of Butte. T. F. Cole of Duluth, Minn., is president.—The managers of the Pittsburgh & Montana Co., who built in Butte a new process smelter which has never worked successfully, claim that part of their processes have been adopted by F. A. Heinze at the smelter of the Montana Ore Purchasing Co., where they are in successful use. In this method the natural fuels which the ores themselves contain are utilized in extracting values through heat produced by the converting process, in lieu of water concentration, heap roasting, calcination or the use of coke or carbonaceous fuel of any kind. The Pittsburgh management claims that its smelter is completed and ready for a run, but that owing to the water in the workings of the mine no ore can be produced. The mine has been flooded for five months. It is understood that one of the new electric pumps has also proved a failure through a mistake made in the construction of the motor and electrical conductor.—The Butte Copper & Zinc Co., controlled by the same New York men who are at the head of the Montana Zinc Co., which is experimenting with a new process for treating the zinciferous

ores of the Alice mine, in Walkerville, has bought the Emma mine, at Butte, from C. E. Dickerman of Minneapolis, Minn. The Emma has carried only zinc and silver, and too much zinc to make it profitable for mining for silver, as the local smelters can not treat zinc ores. It is believed that with greater depth, the shaft now being down 900 feet, the Emma will develop into a copper property, as several of the copper veins to the north dip under the Emma claim.—A new reverberatory furnace is being built in the smelter of the Montana Ore Purchasing Co. and the capacity of the company's concentrator at Basin will also be increased from 1200 to 2000 tons. The new furnace at the smelter will be much larger than any of the others in the plant. The plant is now treating from 1200 to 1500 tons a day. Only one of the four blast furnaces in the smelter is now in operation and is consuming 150 tons a day.

Butte, April 10.

The principle of the ore treatment at the Montana Ore Purchasing Co.'s plant depends, first, upon the production of a lower grade matte from the blast furnace, giving an increased capacity, reduced coke and flux consumption and a consequent reduced slag loss and an increased capacity in the calcining furnaces. The steel converter shells are lined with magnesite brick, next to which is placed a lining of siliceous ore. The converter is then charged with 1000 pounds of siliceous ores in lump form, which is cemented to the bottom and sides of the converter by a small charge of low grade molten matte. A full charge of low grade molten matte is then introduced and the blast turned on after the converter is placed in an upright position. The heat thus produced by the converting action dissolves the ore charge, and thereafter the iron in the matte, after oxidation, dissolves the ore lining. The mineral values contained in each are thus separated from the gangue of the ore and join the bath of molten matte, forming an alloy of copper and precious metals, while the waste materials form silicate of iron, or slag, which, being less in specific gravity than matte or metals, floats to the surface of the bath and is removed. The converting action is continued until the grade of white metal has been reached, and it is thereafter continued until the remaining sulphur, arsenic, etc., have been expelled by oxidation and the resultant bath is thereafter poured, in the form of clean blistered copper, into plates, slabs or bars for shipment to establishments in the East, where electrolytic separation of the precious metals is accomplished.

## NEVADA.

### Elko County.

The Carlson mine and mill at Mardis, near Wells, are being put into shape to resume work this month.

### Esmeralda County.

The Montgomery Shoshone M. Co. has been formed to work the Montgomery-Edwards property at Bullfrog. E. A. Montgomery is president and manager, M. MacDonald vice-president and consulting engineer and J. C. Connors of Idaho Springs secretary and treasurer.—The new camp of Sumo is 7 miles northeast of San Antonio P. O., 10 miles north of Liberty, and 32 miles north of Tonopah, via the Belmont road.

Ore shipments via the Tonopah Railroad for the week ending April 7 were as follows: Tonopah, 871 tons; Montana Tonopah, 206; Tonopah Extension, 225; Tonopah Belmont, 80; Midway, 62; Combination, 60; Goldfield Sampling Ore Co., 248.

Work has been started on the Hart-Goldfield M. Co.'s property near Diamondfield by M. F. Kirkpatrick.

### Lincoln County.

J. C. Kavanaugh will sink a 100-foot shaft on the claims in the Crescent district, which is north of the Searchlight district, and near Los Vegas.—It is reported that a 10-stamp mill will be put in at the Nipino in the same district.

It is reported that the Empire Con. M. & M. Co., near Searchlight, intends to put in a 40-stamp mill. E. B. Scott is manager.

### Lyon County.

E. Boyle, manager of the North Rapidan M. Co., at Como, has started work at the mine. It is reported that a large reduction plant is to be put in.

### White Pine County.

At the Star mines at Cherry Creek the shaft is down 800 feet, and will go on down to the 900-foot level. This mine is being worked by the Glasgow & Western Exploration Co., of which D. M. Boyd of Salt Lake City is secretary.

## NEW MEXICO.

### Doña Ana County.

The Cahallo mountain gold placers, above Rincon, on the Rio Grande river, are being worked by J. H. and M. B. Parker, who are putting in a 9000-foot pipe line.

### Grant County.

Companies working in the Chiricahua mining district, 10 miles northwest of Rodeo, are the Chiricahua Development Co., near Paradise, the Savage Gold & Copper Co., 5 miles east of Paradise, and the Cochise Consolidated Co., 2 miles north of Paradise, who have fifty men employed and expect to put in a 50-ton concentrating plant. J. A. Lewandowski is manager of the Savage Co.

### Otero County.

The Southwest S. & R. Co. has made plans for a 400-ton smelter at Jarilla. The company controls 600 acres of mining claims at Jarilla and is leasing the ground.—The Kansas City Co. has men on the Ruby and Monte Cristo claims at Jarilla and has commenced shipment of ore to the El Paso smelter.

## OREGON.

### Baker County.

A strike of free-milling ore is reported from the Homestake group, near Bourne, belonging to A. E. Dagany, who wishes to put in a 500-foot hoist.—The Midway group, 7 miles from Sumpter, is putting in a 6-drill compressor for deeper sinking. Sinking was suspended at

the property last year owing to the difficulty of continuing with hand drills. The shaft is down to the 200 level, with stations at the 100 and 200. Drifting and sinking are to be continued at the same time.—A strike is reported on the Snow Creek mine, near Greenhorn, in the second crosscut from the 200 level leading from the main shaft. D. P. Smith is manager.—The tunnel being driven through the hill at the Vinson placers, on the north fork of the John Day river, near Granite, has been completed. The bottom is being prepared for carrying water through to the placer ground below, and it is expected to have sluicing operations commence in two weeks.—Bids have been called for driving the main crosscut on the Gold Coin group, near Bourne, Cracker Creek district.—W. Stinson reports satisfactory operations on the Lucy group, near Greenhorn. A crosscut has been run 900 feet, at which point the ledge was tapped. This has been drifted upon in both directions for 150 feet.

The new electric pump at the Baisley-Elkhorn, near Baker City, lifts 500 gallons a minute, and has cleared the mine so that work has been resumed on the main working shaft. The hoist is electric; the mine, inside and out, is lighted by electricity, the power for operating the air drills is electric and everything about the mill is operated by electricity.

#### Grant County.

The New York syndicate owning the drift placer ground on Big creek, near Susanville, is getting ready for drifting and hydraulicking. Water is early.

Development at the Monumental mine, near Granite, is progressing steadily. Manager C. J. Allen of Portland has two power drills on the level 100 feet below the main adit. Arrangements are being made to sink the other shaft 100 feet and explore the same ore body 200 feet below the adit. He says that he is using not to exceed 1½ cord of wood a day to make the compressor supply two drills and also run the hoist and pump.

F. W. Burbridge has the hull of the Crane Flat dredger, near Granite, nearly completed.

#### Jackson County.

D. B. Grant, who is developing the discovery near Panther Butte, 4 miles southwest of Ashland, reports that the tunnel is in 150 feet on the ledge.

#### Josephine County.

Manager J. F. Hopkins of the Calumet & Oregon M. Co., near Kerby, will commence work on the crosscut tunnel that is to open the vein system at the junction of the Illinois river and Rancheria creek.

T. F. Hopkins has started work for the Calumet & Oregon M. Co. on the Golden Eagle group, 11 miles from Selma, on the Illinois river.—B. Healy of San Francisco, Cal., owner of the Jewett mine, on Mt. Baldy, 4 miles southeast of Grants Pass, is expected to put in a cyanide plant at the mine. J. S. Hoar has charge at the mine.

D. L. Smith of the Rand M. Co., operating on Rogue river, at Galice, reports that the main drift is in 600 feet.

F. Clemens intends to open the Yellow Horn 3-stamp mill near Leland.

#### Wallowa County.

Good silver ore has been struck in the Great Northern G. & C. M. Co.'s property on the Wallowa slope of the Eagle range, 20 miles from Joseph. E. T. Schuler is president of the company.

### SOUTH DAKOTA.

#### Lawrence County.

The Gilt Edge-Maid M. Co. has started up its mill, east of Deadwood, under new management, and some improvements have been made in the manner of hoisting the ore and in the mill treatment.—The Minnesota Mines Co. of Minneapolis has struck good ore bodies on a property adjoining the Penobscot, in the Maitland district. They intend putting up a mill.—The Puritan M. Co. is installing plates at its mill, south of Deadwood.—The Clover Leaf M. Co. has started up ten stamps at the mill at Rouhaix and intends to treat ore which has been stored. The company will keep this part of the mill going during the season. The reorganization of the company is soon to be effected, which will increase the capitalization. The company is planning to enlarge the mill and further develop its large ore bodies.

#### Pennington County.

(Special Correspondence).—The shaft house of the Clara Belle M. Co. at Oreville was destroyed by fire on March 28th. The hoisting engine was badly damaged, but the boiler was not much injured. Every effort is being made to keep the pumps going, as this is the wet season. It is expected to rebuild at once.

Oreville, April 10.

### UTAH.

The coal deposits of Utah extend from the eastern Utah boundary near Grand Junction, in a southwesterly direction for nearly 200 miles into Arizona. From that point it can be traced north to Fish Creek on the west line of Carbon county. This coal crops out along the east side of Castle Valley from Castle Gate to Grand Junction and on the west side of Castle Valley, from Fish Creek to Emery and down the Muddy creek into Wayne county. There are four veins of coal from 4 to 30 feet in thickness, the vein lying almost flat, dipping to the northwest about 2°.

#### Salt Lake County.

Superintendent F. B. Whitmore of the Columbus Con. of Alta is reducing eighty tons of ore.

Manager Orem of the Red Wing M. Co., at Bingham, reports that the 3000-foot tunnel being driven to cut the vein is in 800 feet. An air compressor and machine drills are to be put in to expedite work.—D. C. Jackling has started work on the old tunnel which starts on the Utah Copper Co.'s ground above the Rogers mill at Bingham. This will be cleaned out and extended into the Ohio Co.'s ground.—F. B. Cook of the Cluster Co., at Bingham, reports that the tunnel being driven to a connection with old workings on the opposite side of the hill is in 1200 feet, and it is calculated that 20 feet more will take

it to the old shaft.—Work has been resumed on the Conger group, adjoining the Starless, at Bingham. The 500-foot tunnel is to be extended and a chute to deliver the waste rock is being huilt over the Copper Belt track.

—It is reported that the U. S. M. Co. at Bingham will add three lead-blast furnaces to the present battery, making six, having a capacity of 800 tons daily.

At the South Columbus mine at Alta they will put in another machine drill and lay a new pipe line. During March one shift in the tunnel made 65 feet, at a cost of \$15 per foot. The tunnel is in 915 feet.

It is announced that the Lark vein of the Dalton & Lark property at Bingham has been cut by the Mascot tunnel 8000 feet from its mouth and at a depth of 1500 feet. The vein shows a large body of high-grade galena.

#### Utah County.

Operating mines in the American Fork canyon are the Wyoming, by G. Tyng; Healy, by the American Fork M. Co.; Whirlwind, by the Whirlwind M. & M. Co.; Blue Rock, by the Pacific G. M. & M. Co.; Bog and Dutchman mines, by the Dutchman M. Co.; Clipper and Silver King mines, by the Clipper & Silver King Con. M. Co.

J. H. Wooton of American Fork expects to start work in the Hot Stuff mine in American Fork canyon, which is owned by the Goodsell M. Co.—C. D. Hanks of American Fork is operating the Shamrock prospect on the Millar hill in American Fork canyon.—Work has been resumed at the Blue Rock mine, in American Fork canyon.

L. Western and Webb Bros. will run a 150-foot tunnel to tap the galena vein of the Cedar Stump, near the mouth of American Fork canyon.

#### Weber County.

D. Maguire of Ogden reports that development work at the properties of the Santa Maria Co. in the Sierra Madre mountains, north of Ogden, is progressing. Adjoining the Santa Maria, Wm. Hunt and associates are running a tunnel to open the vein.

### WASHINGTON.

#### Ferry County.

The Mineral Hill T. & M. Co. has been formed with a capitalization of \$1,500,000, with A. Vittum, Beverly, Mass., president; S. A. Boone, Boone, Iowa, vice-president; D. H. Whipple, Boston, Mass., secretary and treasurer; F. E. Houghton, Boston, Mass., general manager; A. L. Bradley, Spokane, auditor. The manager at the mines is S. L. Boyer. The properties are in the Curlew mining district, on the line of the Spokane & Northern and the Kettle Valley Railroad, 1 mile south of Danville. The company intends to drive a tunnel to intersect ledges on Mineral hill at a depth varying from 600 to 1800 feet. A fee will be charged for all ore passing through the tunnel, the price being regulated according to the value of the ore. A charge will also be made for drainage.

#### Okanogan County.

E. C. Waters of Columbus, Ohio, and J. Rausch of Marysville, Ohio, are at Chesaw inspecting the properties of the Interstate M. Co. They intend to put in a compressor and machine drills at the Delate and Keystone and will increase the concentrator from ten to sixty tons daily capacity.

#### Snohomish County.

W. J. Walters of Portland, manager of the Smuggler Gold and Copper M. Co. at Index, reports that the tunnel is in 165 feet. The company intends to run the tunnel 400 feet, when it will crosscut.

#### Stevens County.

The Blue Bell Gold & Copper M. Co.'s claims on Sofia mountain, 15 miles west of Northport on Sheep creek, has been worked all winter under Superintendent Fred. Friedland. The 400-foot tunnel being run to tap the ledge at a depth of 700 feet is in 300 feet.—The Chewelah Marble Co.'s property on Deep creek, 5 miles east of Northport, is ready to be worked by Superintendent Hanke.

Manager D. F. Strobeck has commenced work on the Independence-Keystone M. Co.'s property, 6 miles north-east of Chewelah. A tunnel will be run in on the ledge to tap the main ore shoot.

### WYOMING.

#### Uintah County.

A. J. Parshall of the U. S. Geological Survey confirms the report of the discovery of rich gold deposits near Kendall.

### FOREIGN.

#### BRITISH COLUMBIA.

#### Boundary District.

The Winnipeg shaft, in Wellington camp, has been unwatered to the 400-foot level.—The new shaft of the Emma mine, at Summit, is down 75 feet.—A. Anderson has given an option on the Jack Pot, at Wellington, to local parties.

The Boundary output for March was: Granby mines, 55,798; Mother Lode, 13,504; Brooklyn-Stemwinder, 10,474; Rawhide, 7933; Mountain Rose, 846; Emma, 885; Oro Denoro, 325; Elkhorn, 60; Skylark, 125; Last Chance, 27; E. P. U., 20; Miscellaneous, 50. Monthly totals, 90,047 tons. The Great Northern railway, which was built to Phoenix camp last year, began hauling ores for the Granby Co. about the middle of February, and the output over this line of railway alone is about 1000 tons daily, while the C. P. R. handles the balance. Part of the three months last past there have been ten blast furnaces in operation in the Boundary smelters, six at the Granby, two at the B. C. Copper and two at the Montreal & Boston. During part of the winter there was a shortage of electric power, which is brought 22 miles from the falls of the Kettle river at Cascade. Negotiations are pending for the erection of a smelter at Midway, where such works could be served by both the Canadian Pacific railway and the Great Northern. An option has been given on a portion of the Midway townsite and on the Sullivan ranch near by for this pur-

pose. Preliminary surveys for the new smelter have also been made. As the B. C. Copper people are about ready to make extensive improvements to their smelting plant, there is a belief that the new site is for them.

A. D. McPhee, superintendent of the McKinley mine, Franklin camp, has started work with ten men.

#### Nelson District.

The Hall M. & S. Co. at Nelson has closed down its lead stack for want of ore. At the trail smelter—the single operating lead stack out of three available ones—will close down for want of silver-lead ore. The trouble is reported to have arisen from the Slocan miners over-estimating their probable output when it was agreed to let the St. Eugene ship abroad. The St. Eugene agreed to supply the difference required to keep the home smelters busy, but although it has each month sent more than half of the ore supplied to Trail and Nelson, the other silver-lead mines have failed to output anything like the amount originally estimated. The St. Eugene during March milled and shipped 3700 tons of concentrates. Of the concentrates made, 2300 tons were shipped to Germany, 80 to Belgium and the remaining 600 tons were sent to the Nelson and Trail smelters.

#### Rossland District.

The Le Roi No. 2 has under contemplation \$50,000 worth of development work, including the deepening of the shaft to the 1450-foot level, which would be 550 feet below the present lowest workings. The Center Star is extending its workings down below the ninth level. The Le Roi is extending the winze from the 1450-foot level down to the 1550-foot level, and the era of deeper mining has begun.—The shipments for the week ending April 8th were: Le Roi, 2800 tons; Center Star, 2050; War Eagle, 1410; Le Roi No. 2, 50; Le Roi No. 2 milled, 1200; Spitzee, 180. Total for the week, 7690, and for the year, 96,904.

#### Slocan District.

J. McKenzie has purchased five-eighths interest in the Gold Bug and Copper Cent. on Cariboo creek, in Upper Duncan district, from W. Williams for \$2000.—It is reported that the Jackson mill and mine at Whitewater will start up April 15. Both have been closed down for some years. At the mine a little work has been going on in the way of leasing or contract, since the company operation ceased, and a good strike of ore was made by the workers last year.—Reports have come out that a rich shoot of ore has been struck on the Fisher Maiden at Silverton. Some time ago a raise was started at a point 300 feet from the portal of No. 4 tunnel. Some rich ore which was met looked so promising that a drift was started to ascertain its extent. This has been run over 50 feet and the ore continues.

### MEXICO.

The following constitute the reforms desired, by the mining men of Mexico, a number of which have been passed as laws: The suppression of the 2% coinage tax on the value of silver, established by the decree of March 27, 1897, and its reduction to 1% in the case of gold. Reduction to cost of the duties on separating, assaying, reducing and refining, and the application of those duties exclusively to hars of metal presented to the mints for those operations. Reduction of the 3% stamp tax on the value of gold and silver to 1%. Reduction of the 2% State tax on the value of gold and silver to 1½%. Monthly fixing, by the finance department, of the price of silver, copper and lead, which is to serve as basis for the collection of Federal and State taxes, this price to be founded on the average quotation of those metals on the New York market during the preceding month. Reduction by 10% of the assay estimate in the collection of the duties on ores that are to be shipped from one State to another or exported from the republic. This must be done by deducting from the weight of the ore that of the moisture which it contains. Reduction, from \$10 to \$5 per pertenenca, of the tax on gold, silver and platinum mine titles, as established by the law of June 6, 1892. Reduction, from \$10 to \$5 per pertenenca, of the annual property tax on gold, silver and platinum mines as established by the previously mentioned law. Exemption from import duties for the articles here enumerated—sulphuric acid, mercury, sulphur, coal and coke, alkaline cyanides, hyposulphates, mine timber, nitrates of potash and soda, sulphate of copper, sheet zinc for metallurgy, and machinery and apparatus for mines and metallurgical establishments. Adequate protection, by the executive, of ore treating establishments, which, employing new processes, such as cyanidation, are erected for the treatment of low-grade ores or of dump accumulations from old mines.

A new mining law was passed on March 25th in the City of Mexico, to take effect July 1, by which the value of the special stamps in conformity with the laws in force, which should be affixed to titles to mining properties, will be \$5 for each pertenenca applied for—no matter what the mineral substance may be. The annual tax on mining properties shall be regulated in the following terms: (a) There shall be paid \$6 annually for each mining pertenenca, or \$2 for each third annual payment—no matter what the mineral substance may be. (b) In case the number of pertenenencias in one mining enterprise shall exceed twenty-five, and these pertenenencias all join one with the other, the price of \$6 shall apply solely for the first twenty-five pertenenencias, and there shall be paid \$3 for each pertenenca which exceeds twenty-five. Denouncements for mining pertenenencias shall not produce any legal effect whatever if the same is not accompanied with a certificate issued by the local stamp office, which certificate shall certify that there has been deposited in the aforementioned office the cost of the title in accordance with the number of pertenenencias contained in the denouncement. This certificate of deposit shall be returned to the interested parties as soon as the stamps paid for are cancelled on the title or the denouncement shall have been finally dismissed.

#### Chihuahua.

The Hidalgo M. Co. have encountered a new body of pay ore in the croppings of the Veta Colorada, next to the hanging wall side of their former operations on the

**Alfarcena, near Parral.**—The Cigarrero M. Co. is completing arrangements for a cable tram from their mine to the railroad station at Baca.

The Parral M. Co. have closed down their concentrating plant at Parral for repairs.—The three-compartment shaft of the El Faro mine of the San Nicholas Co. at Parral is down 150 feet.

#### Jalisco.

An experimental plant has been built to treat the milling ores of the Santo Domingo and other mines of the Amparo M. Co., near Ahualulco. If successful, a 100-ton plant is to be put in at the foot of the mountain in which the company's mines are located and to transport the ores 1½ mile from the mines by an aerial tramway. It is proposed to make the shaft a three-compartment and to put in a hoist. F. Sustersic is manager.

#### Mexico.

The Compania Minera Las Dos Estrellas at El Oro is adding forty stamps to their present 80-stamp mill and cyanide plant. H. Bessaut is manager.

#### Sonora.

Work is to be resumed on the Morene mine, 16 miles from Nacozari, by A. J. Borie.—The Transvaal M. Co., near Cumpas, in the Mictetuzuma district, is putting in a reduction plant. They have some 500 men working. O. L. Neer is manager.

#### Tepe.

T. E. Smith will build a cyanide plant at La Yosca for the Zapopan G. M. Co.—W. Warren, owner of Los Saltos property, near Barranca del Oro, proposes to put in an impact water wheel to give power for working his mine.

#### PERU.

J. D. McKenzie, who has been constructing the 1000-ton smelter at Cerro del Pasco, reports that everything is to be handled automatically by electric power, for which they have a 4000 H. P. plant. All the buildings are of steel. The smelter site is 14,000 feet above sea level, while the mines are 1000 feet higher, a 7-mile railroad conveying the ore from the mine to the smelter where it is automatically dumped into the ore bins. They employ 6000 men, of which seventy-five are Americans and Englishmen and the balance Peruvians. The principal mine is developed to a depth of 400 feet. A. H. Kennedy has charge of the construction of the smelter.

## Books Received.

"Year Book and Views of the Michigan College of Mines," Houghton, Mich., F. M. McNair president.

"Report of the State Bureau of Mines of Colorado for 1903-4," by E. L. White, gives an account of accidents and legislation affecting the mining industry of the State, together with a summary of mineral production.

"Preliminary Report on the Geology and Water Resources of Central Oregon," by Israel C. Russell, is the result of a reconnaissance to investigate artesian water supply, but in addition gives an interesting account of the physiography and geology of this little known region. It forms bulletin 252 of the United States Geological Survey.

"Development of Lake Superior Copper Mines During 1904," by A. L. Carnahan, gives a concise statement of operations at each of the mines for the past year. It states that on January 1, 1905, the Tamarack No. 3 vertical shaft was down 5066 feet and the Calumet shaft down 8100 feet on the incline, being the two deepest shafts in the world.

The recent work of the United States Geological Survey in studying water supply and irrigation is embodied in a number of reports including "Underground Waters of Washington," by H. Landes; "The Disposal of Strawboard and Oil Well Wastes," by R. L. Sackett and I. Bowman; "Hydrography of the Susquehanna River Drainage Basin," by J. C. Hoyt and R. H. Anderson, and "Pollution of Lake Champlain," by M. O. Leighton.

Truly the miner and prospector is a nomad, and like his Arabic predecessor he leaves but slight record of his wanderings. Hence it is with considerable interest that one reads "In the Footsteps of Pizarro," by W. C. Agle. This gives a detail of the experiences of a Yankee miner in the placers of Peru, "the Klondike of South America." It tells of no great enterprises, but is simply a record of daily experiences in an uphill fight against adverse conditions. Its chief value lies in its minute portrayal of a country and people surrounded with natural advantages that they seem to lack the energy to develop. It will prove interesting reading to prospectors or others wishing a knowledge of modern Peru. It is published by H. M. Hall, Seattle, Washington, for \$1.50 and will be sent postpaid by the MINING AND SCIENTIFIC PRESS upon receipt of price.

"A Treatise on Concrete, Plain and Reinforced," by F. W. Taylor and S. E. Thompson, forms the latest addition to the recent literature on this important subject. It has been designed for practicing engineers and contractors, and also as a text and reference book on concrete for engineering students. The work seems authoritative and accurate and contains information on every branch of the subject, arranged particularly for convenience of reference. The simple directions for concreting will be easily understood by any contractor, while the elaborate calculations and formulas for reinforced concrete will interest the civil engineer. The one volume gathers together material that has been widely scattered and presents it in readable form. It is published by John Wiley & Sons of New York City for \$5, and will be sent postpaid by the MINING AND SCIENTIFIC PRESS upon receipt of price.

## Personal.

J. MOORE is superintendent Aztec Co., Needlton, Colo.

IRA A. CAMMETT is in Denver, Colo., from Los Angeles, Cal.

H. P. SAUNDERS has returned to Salt Lake City from Denver, Colo.

ROBERT CLARK, of Kalgeerlie, West Australia, is in Denver, Colo.

W. G. YOUNG is superintendent Gold Reef mine, near Kendall, Mont.

M. B. KERR, San Francisco, is experting a mine near Placerville, Cal.

GEO. HILL is superintendent Shenandoah mine, near Silverton, Colo.

W. T. COPE has returned to Grants Pass, Or., from an Eastern trip.

J. W. NEILL has returned from San Francisco, Cal., to Butte, Montana.

F. J. SPARL is manager Pompeii mine, 3½ miles north of Searchlight, Nev.

W. B. STEWART is superintendent Continental mine, near Myrtle Creek, Or.

M. R. LAMB of San Francisco, Cal., is sampling a gravel mine, near Leland, Or.

R. CHRISTENSON has succeeded J. Oates as foreman Bunker Hill, near Amador City, Cal.

JOHN FREISE is manager Goldfield-Scorpion Co.'s properties at Goldfield and Lida, Nev.

J. B. TOMLINSON of Prescott, Ariz., is at his mine in the Bacoachi district, Sonora, Mexico.

ED. PRINTZ, Bishop Creek, Inyo county, Cal., is at Quincy, Ill., at the Plumas M. & M. Co.

GEO. OTTERSON has charge Marshfield G. M. Co.'s placers near Marshfield, Coos county, Or.

T. K. CODE is superintendent Empire mine at Gold Valley, near Downioville, Sierra county, Cal.

H. H. DYER is superintendent Shannon mines at Metcalf, Ariz., succeeding W. T. Climo, resigned.

E. F. SPARROW has succeeded E. I. Leach as superintendent Gold Treasure M. Co. near Naco, Ariz.

M. G. HAVECK is superintendent Montgomery Shoshone M. Co., ¼ mile from Rhyolite, Nye county, Nev.

C. M. LAMB, superintendent Iyanough M. Co., at Dupont, near Lincoln, Nev., has been at Los Angeles, Cal.

E. J. COLLINS has been appointed superintendent Wolverine & Arizona M. Co. at Bisbee, Cochise county, Ariz.

J. L. SCHOFIELD, formerly of Deadwood, S. D., is superintendent Coronado C. Co.'s mines at Metcalf, Ariz.

A. D. MARSHAL has been placed in charge of work at the California and Black Cloud mines, near Wallace, Idaho.

A. M. JENNINGS is manager and R. Kellogg superintendent Southern Nevada M. & M. Co., near Searchlight, Nev.

N. T. MANSFIELD, manager Smuggler-Union mine at Telluride, Colo., has been examining mines, near Searchlight, Nev.

F. W. HOAR has been appointed manager Chiricahua Development Co.'s property at San Simon, Cochise county, Ariz.

C. LUCAN has been appointed general manager Lomas de Oro M. Co., working the Yauco mines near Rosario, Sinaloa, Mexico.

C. M. FUELLER has returned to Denver, Colo., from Chloride, Ariz., where he has been making examinations of mining property.

S. J. TRUSCOTT, superintendent Redjang Lehong mine at Lehong Donok, in Sumatra, will arrive in London, England, May 1.

WM. E. MILLER, secretary, and John Wilson, a director Arizona C. Co., have been at Clifton, Ariz., from Edinburgh, Scotland.

W. L. COBB, of San Francisco, Cal., is making an examination of the Glenn Con. mine, with a view of its development on a larger scale.

B. F. CLOSE, formerly superintendent Helvetia M. Co., has been appointed consulting engineer Arizona Commercial Co., at Globe, Ariz.

MR. NEVILLS of Chicago, Ill., will take charge of the Selby Smelting Works at Vallejo Junction, Cal., vice A. von der Ropp, resigned.

C. E. CONDIT, superintendent Astor M. & M. Co., near Eureka, San Juan county, Colo., has gone East, supposedly to purchase a milling plant.

JAS. McNAUGHTON, superintendent Calumet & Hecla M. Co. at Calumet, Mich., has been examining mines in the Warren district, near Bisbee, Ariz.

R. E. BREWSTER, president Harward G. M. Co., has returned to Boston, Mass., from a visit at the company's mine at Jamestown, Tuolumne county, Cal.

C. H. McMAHON has resigned as superintendent Motezuma Lead Co. of Santa Barbara, Chihuahua, Mexico, and has opened an office at El Paso, Texas.

A. WATTERS, in charge After Supper mine near Black Hawk, Colo., has been appointed local agent for

the Clark-Gardner mine on Quartz hill, near Nevada, Colo., owned by the Reme-Gardner M. Co. of Reme, N. Y.

B. S. REVETT, interested in hydraulic mining in California, Alaska and Colorado, has returned from San Francisco, Cal., to Breckenridge, Colorado.

D. H. LAWRENCE, Breckenridge, Colo., is consulting engineer Mary Verna M. Co., at Frisco, Colo., and the North American M. Co. at Uneva Lake, Colo.

H. E. WHIPPLE of Los Angeles, Cal., is superintending the construction of a cyanide plant for the Black Mountain M. Co. at Cerro Prieto, Sonora, Mexico.

R. D. EVANS of Boston, Mass., has been in San Francisco, Cal., attempting the consolidation and sale of Oroville dredging properties in which he is interested.

A. D. MARSHALL, formerly in charge Standard mine before its merger into the Federal combine, has accepted the management Heinz Lead & Silver M. Co., at Wallace, Idaho.

FRANK LONGMAID has resigned his position with the Velardena M. & S. Co. and is now with the Vacas-San Marcos M. & M. Co., Vacas, Durango, Mexico, as general manager of that company.

RICHARD HANCOCK, superintendent Mysore and Champion Reef mines in India, has retired on account of poor health, being succeeded by Arthur Gifford and T. E. Piercey, respectively, at these mines.

J. KIRK FIRTH has resigned his position with the Joshua Hendy Machine Works of San Francisco, Cal., and is now associated with the Allis-Chalmers Co., whose San Francisco, Cal., office is 623 Kohl Building.

P. B. ETESON, who for six years has been in charge of the Kia Ora dredger, near Oroville, Cal., has gone to Placerville, Idaho, to take charge of a dredger being built by the Risdon Iron Works of San Francisco, Cal.

J. P. TURNER has resigned as superintendent Yankee Con. mine, at Eureka, Utah, and for the present the property will be conducted by Consulting Engineer H. L. Burton and F. Gardinier and C. Zabriskie, shift bosses.

W. B. GRIFFITHS has resigned as engineer with O. y T. Braniff, Macon, Est. de Queretaro, Mexico, to accept the superintendency of the Guerrero Mining & Exploration Co., Los Grados, Rio Balsas, Est. de Guerrero, Mexico.

## Obituary.

W. L. COULTER, superintendent Paymaster mine, at Tonopah, Nev., died there April 11 of pneumonia.

J. E. HILL, JR., manager and secretary Pittsburgh Con. Co., at Alta, Utah, died April 8th of constitutional ailments.

## Commercial Paragraphs.

A. B. Saurman, Rialto Building, San Francisco, Cal., is Pacific coast manager for the Standard Underground Cable Co. of Pittsburg, Pa.

THE South Side Elevated Railway Co. of Chicago has contracted with the Westinghouse Electric & Manufacturing Co. for complete equipments of seventy cars, which includes 140 75 H. P. motors, and multiple control apparatus. The motors are of special design and are in line with the re-equipment of this system. The cars will be operated in trains of five, three of which will be motor cars.

THE Jeanesville Iron Works Co. reports recent shipments from their Denver, Colo., branch as follows: Victor Fuel Co., one compound pump, 800 gallons capacity, 650 feet lift, through 16,000 feet of pipe; one mine pump, compound, 800 gallons capacity; one high lift station pump to Boulder county; two sinkers to local dealers; four Wyoming steam separators to Mexico, five to Arizona, two to Salt Lake City, two to coal mines in Colorado.

THE Butters Copala Syndicate of San Francisco, Cal., has shipped to Mazatlan, Mexico, from the West Allis, Milwaukee, works of the Allis-Chalmers Co. two heavy duty Reynolds-Corliss engines. These, with other heavy machinery included in the order, are to form part of a large plant to be installed by Sept. 1, 1905, at the mines of the syndicate, where a complete cyanide plant is under construction. The Butters Copala Syndicate has acquired the contract that Chas. Butters & Co., Ltd., had with Felton Bros. of Mazatlan to operate the properties of Felton's Copala Mines, Ltd. These constitute a consolidation of the properties in and about Copala, Sinaloa, Mexico.

H. L. SINCLAIR, 1744 Broadway, Denver, Colo., representative of the Hardsog Wonder Drill Co., Ottumwa, Iowa, reports the sale of one belt-driven compressor and two drills for the Tornado M. Co., Del Norte, Colorado; machines for the Lucania Tunnel Co., Idaho Springs, Colo., and drills for the West Gold Hill M. Co., Tincup, Colo., and drills for the Gold Cup M. Co., Tincup, Colo. The main office at Ottumwa report the sale of fifty machines in one order to the Langlaagte Estate M. Co., Johannesburg, South Africa. The Langlaagte Estate M. Co. purchased one of these drills some time ago and made a thorough test of it, and the next order was for six and one ton of bits, and then increased their order to fifty more.

COLORADO IRON WORKS Co. of Denver, Colo., report recent shipments as follows: One carload of smelting machinery to the Lost Packer Co. in Idaho; two car-

loads of concentrating machinery to the El Cobre Co. in Cuba; three carloads of smelting machinery and equipments to the National Metallurgical Co. in Mexico; one carload of smelting machinery to the Mowry Mines Co. in Arizona; impact screens to the Western Ore Supply Co. in Utah and the Economic Gold Extraction Co. in Colorado; a special order of slag trucks for the R. J. C. Mining Co. in Mexico; smelting equipments, consisting of jackets and special machinery, for the North American Copper Co. in Wyoming and smelting machinery and supplies to the Independent S. & R. Co. in Colorado. A 48x160 silver-lead furnace for the Compagnie Francaise des Mines du Laurium, operating in Greece, was shipped this week.

THE J. Geo. Leyner Engineering Works Co. of Denver, Colo., manufacturers of rock drills, air compressors, hoisting engines, etc., report among recent shipments: One 18x22-inch simple steam actuated, two-stage air compressor; two 16x18-inch two-stage air compressors, direct connected to electric motor; one 12x14-inch two-stage air compressor, direct connected to electric motor; three upright duplex steam-actuated air compressors; twenty-four Water Leyner rock drills. For the Gunnison irrigation tunnel, one 22x26-inch compound steam, two-stage air compressor; one 16x18-inch compound steam, two stage air compressor; one 10x12-inch simple steam, single-stage air compressor; two 9x12-inch double cylinder, friction clutch, geared hoists; five 80 H. P. boilers; two small vertical boilers; a number of Water Leyner drills, mine cars, etc. In Colorado they also report sending to the Cripple Creek Homestake Mining Co. one 16x18-inch simple steam actuated, two-stage air compressor; one 12x20-inch double drum hoist; one 125 H. P. boiler; Water Leyner drills, etc. Maid of Orleans mine, 16x18-inch simple steam actuated, two-stage air compressor; 10x14-inch double cylinder, friction clutch, geared hoist; 125 H. P. boiler; Water Leyner drills, etc. City of Cripple Creek Mining Co., 16-18-inch simple steam actuated, two-stage air compressor; Water Leyner drills, etc. St. Louis Mining Co., 12x14-inch simple steam actuated, two-stage air compressor. Rogers & McCreary, upright duplex, belt-driven compressor; Leyner rock terrier drills. American Zinc & Chemical Co., 10x12-inch simple steam, single-stage air compressor. Standard Coal & Land Co., 14x16-inch simple steam actuated, two-stage air compressor. Sunnyside Coal Co., 10x14-inch double cylinder, friction-clutch, geared hoist. Newcastle Coal Co., 6x8-inch double cylinder, friction-clutch, geared hoist. To Nevada, for the Giroux Consolidated Mines, a 10x14-inch double cylinder, friction clutch, geared hoist and an 80 H. P. boiler. California, Union Copper Co., 14x16-inch simple steam actuated, two-stage air compressor; 12x16-inch double drum hoist; Water Leyner rock drills, etc. Washington, Copper World Extension Mining Co., 12x14-inch simple steam actuated, two-stage air compressor; Water Leyner drills. Arizona, Weldon Gold & Copper Co., 8x10-inch double cylinder, friction-clutch, geared hoist, etc. Sweden, two upright, belt-driven, duplex air compressors, drills, etc.

## Trade Treatises.

Bulletin 53 A from the Sullivan Machinery Co., Chicago, describes their straight-line two-stage classes W B 2 and W B air compressors.

The Ajax drill sharpener and Ajax armored pneumatic blasting car are described and illustrated in detail in a 16-page pamphlet issued by the manufacturer, T. H. Proske, 1734 Fifteenth street, Denver, Colo.

The second number of "Air Power," published by the Rand Drill Co., 128 Broadway, New York City, contains "Natural Gas Pumping Plant at Hundred, W. Va.," "Graphics of Boyle's Law" and "Economy in the Operation of Coal Mines From Power Plants."

## New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING APRIL 4, 1905.

786,710.—SHINGLE GAGE—A. Anderson, Bellingham, Wash.  
786,403.—CAN TOPPING MACHINE—H. C. Black, San Francisco.  
786,404.—CAN TESTING MACHINE—H. C. Black, San Francisco.  
786,480.—CASING SPEAR—J. J. Breuster, San Francisco.  
786,482.—FRUIT PITTER—J. Caldwell, Los Angeles, Cal.  
786,265.—ORE CRUSHER—A. C. Calkins, Los Angeles, Cal.  
786,484.—PIANO CHAIR—Mary C. Carrick, San Francisco.  
786,266.—FURNACE—N. Cartmel, Los Angeles, Cal.  
786,729.—CURTAIN HANGER—J. J. Cochran, San Francisco.  
786,487.—HOP PICKING BASKET—F. W. Craver, Santa Rosa, Cal.  
786,489.—TROLLEY POLE—M. O. Dolson, Los Angeles, Cal.  
786,432.—VALVE GEAR—W. R. Dow, Boulder Creek, Cal.  
786,562.—CAMERA—G. Hassell, San Francisco.  
786,761.—STEAM GENERATOR—C. E. Hastings, Griffin, Cal.  
786,788.—WRENCH—M. F. Hudson, Los Angeles, Cal.  
786,787.—VISE—M. F. Hudson, Los Angeles, Cal.  
786,441.—FILTER—B. Hunt, San Francisco.  
786,500.—PUMP—A. A. Kepner, Lemon, Cal.  
786,571.—PAPER HOLDER—G. Laube, Los Angeles, Cal.  
786,505.—JAR TOP REMOVER—W. F. Loofhourrow, Issaquah, Wash.  
786,506.—MOP HOLDER—J. C. Look, Tudor, Cal.  
786,451.—HINGE—J. Lupino, Los Angeles, Cal.  
787,773.—BRIQUET MACHINE—H. E. Marsh, Los Angeles, Cal.  
786,500.—STAMP MILL—A. McCombie, Grass Valley, Cal.  
786,395.—FLUMES—G. T. McIntyre, Riverside, Cal.  
786,581.—PROCESS—H. E. Miller, Oakland, Cal.  
786,672.—EXERCISING APPARATUS—G. H. Pfund, San Francisco.  
786,534.—PUMP—J. Richards, San Francisco.  
786,316.—RAILWAY SIGNAL—W. G. Roome, Los Angeles, Cal.  
786,526.—PIRE SCREEN—V. P. Solom, San Francisco.  
786,529.—APPLYING REMEDIES—D. A. Stapler, San Francisco.  
786,692.—ENVELOPE FASTENER—E. J. Steventon, Davisville, Cal.  
786,693.—SOFA AND TABLE—N. B. Stone, Outlook, Wash.  
786,335.—SAW HANDLE—D. Worden, Whatcom, Wash.

## Dividends.

The Reco M. Co. of Sandon, B. C., will pay 2% dividend April 20.

## Latest Market Reports.

SAN FRANCISCO, April 14, 1905.

### METALS.

SILVER.—Per oz., Troy: London, 26½d (standard ounce, 925 fine); New York, bar silver, 56½c, refined (1000 fine); San Francisco, 56½c; Mexican dollars, 46c, San Francisco; 43½c, New York.

COPPER.—New York: Standard, \$15.37½; Lake, 1 to 3 casks, \$15.25@15.37½; Electrolytic, 1 to 3 casks, \$15.37½; Casting, 1 to 3 casks, \$14.87½. San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18@24c. London: \$67 7s 6d spot per ton.

Following are the figures for the German consumption of foreign copper for the months of January-February, 1905, compared with the same period of time for 1904-1903:

	1905.	1904	1903.
Imports, tons.....	15,884	19,778	12,504
Exports, tons.....	1,937	1,215	1,725
Consumption, tons.....	13,947	18,563	10,779

Out of the above, 13,099 tons were imported from the United States.

The difference between the figures representing the consumption of copper during the several periods above mentioned does not necessarily represent the actual condition of the industries in Germany at these periods, for the succeeding months may show a greater or less amount consumed. The demand for copper in electrical work in Germany is constantly increasing, as it is in every progressive country where industrial life is such a pronounced feature of its existence. The United States, Germany and England are the principal consumers of the copper production of the world, though vast amounts are used elsewhere.

LEAD.—New York, \$4.60; Salt Lake City, \$3.50; St. Louis, \$4.12½; San Francisco, \$3.70, carload lots; 4½c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5½c; pig, \$4.85. London: £12 16s 3d pig long ton.

SPELTER.—New York, \$6.00; St. Louis, \$6.15; London, £23 12s 6d per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

TIN.—New York, pig, \$30.95@31.25; San Francisco, ton lots, 32c; 500 lbs., 31½c; 200 lbs., 32c; less, 33c; bar tin, 34c, 35@37½c. London, £145.

PLATINUM.—San Francisco, crude, \$18.50 per oz.; New York, ingot, \$19.50 per Troy oz. Platinum ware, 75@82c per gram.

QUICKSILVER.—New York, \$40.00@41.00, large lots; London, £7 12s 6d; San Francisco, local, \$38.00 per flask of 75 lbs.; Denver, \$45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 20c; San Francisco, Plumbers', 100-lb. lots, 16.75c.

ZINC.—Metallic, chemically pure, 50c; dust, 40c; 10c; sulphate, 30c, 40c.

NICKEL.—New York, 55@60c per lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c per lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburgh. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburgh.

### STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$16.35@16.85; gray forge, \$16.65; San Francisco, har, 3c per lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburgh, \$23.00@27.00; open hearth billets, \$23.00@27.00; San Francisco, har, 7c to 12c per lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, 4c per lb. above kegs price; in 1 and 5-lb. tin cans, 100 lbs. per case, 4c per lb. above kegs price. Dry Lead.—In hhls., 1 ton and over, 6½c; do. in kegs, 7c.

LUMBER.—(Retail): Pine, ordinary sizes, \$24.00@5.00; extra sizes higher; redwood, \$28.00@30.00; lath, 4 feet, \$4.50@5.00; pickets, \$21.00; shingles, \$2.50 for No. 1 and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00@35.00.

LIME.—Santa Cruz, \$1.25 country, \$1.25 city per bbl.

CEMENT.—Imported, \$2.15@2.65 per bbl.; California, carload lots, \$1.90 f. o. b. at works; small lots, \$2.20 per bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

NAILS.—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.55; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d, Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4d and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

### GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 7½c; Hallett's, 7½c; San Francisco, 1000-lb. lots, 9c; 300@500-lb. 9½c; 100-lb. lots, 10½c.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lot, Eastern and foreign: Wallsend, \$7.50; Brymbo, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8.00; Cumberland, \$13.00; Cannel, \$8.50; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13.00 in sacks; Sunnyside, \$8.50, long ton.

POWDER.—F. o. h. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1\*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1\*\*, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg.

CAPS.—3x, \$5.50@6 per 1000; 4x, \$6.50@7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

FUSE.—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c per set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c per lb.; carloads, 23@23½c; in tins, 30c; soda ash, \$2.00 per 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c per lb.; Cal. s. soda, hhls., \$1.10@1.20 per 100 lbs.; sks., 90c@1.00; chlorate of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2½c; powdered sulphur, 2½@2½c; flour sulphur, French, 2½@—c; alum, \$2.00@2.25; California refined, 1½@2c; sulphide of iron, 8c per lb.; copper sulphate, 5½@5½c; chloride of lime, spot, \$2.50@2.75; sulphuric acid, in carboys, 66% B. 1½@2c per lb.; nitric acid, carboys, 8c per lb.

OILS.—Linseed, hoiled, bbl., 60c; cs., 65c; raw, hbl., 58c; cs., 63c; Lucol oil, hoiled, hbl., 51c; cs., 56c; raw hbl., 49c; cs., 54c. Kerosene—Pearl, per gal., 19c; As, 19c; Star, 19c; Extra Star, 22c; Eocene, 21c, Elaine, 25c; Water White, in bulk, 12½c; Mineral Seal iron hhls., 18c; wooden hhls., 20½c; cs., 24c; Minera; Sperm, cs., 26½c; Deodorized Stove Gasoline, hulk, 16c, do., cs., 22½c; 86° Gasoline, hulk, 25c; do., cs., 31c; 83° Naphtha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, hbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 63c; Bleached, do., 57c; Whale Oil, cs., 52@57c.

BORAX.—Concentrated, 6@7c per lb.; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5@6c per lb.; No. 1, 4@5c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c per lb.

MOLYBDENUM.—Best, \$2.75 per lb.

CHROMIUM.—90% and over, per lb., 80c.

PHOSPHORUS.—American, per lb., 70c.

SODIUM.—Metal, per lb., 60c.

BISMUTH.—Subnitrate, per lb., \$2.10.

URANIUM.—Oxide, per lb., \$3.50.

MERCURY.—Bichloride, per lb., 77c.

TUNGSTEN.—Best, per lb., \$1.25.

SILVER.—Chloride, per oz., 90c@1.00; nitrate, 55c.

RED LEAD.—500 lbs. and over at one purchase, per lb., 7c; less than 500 lbs., 7½c.

MANGANESE.—Black oxide, per lb., 2½@4c.

MAGNESIUM.—Pure, N. Y., \$1.60.

FIRE BRICK.—Domestic, carloads per 1000, f. o. h., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skewback, \$30.00; circle, \$32.00.

FIRE CLAY.—Domestic, per ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, \$8.50.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

DEVICE FOR APPLYING REMEDIES.—No. 786,529. April 4, 1905. D. A. Stapler, San Francisco, Cal. This invention relates to a device which is especially designed for applying remedies or medications to wounds, cavities and the like. The object of this invention is to provide a flexible expansible tampon having a cavity or depression formed at one end within which the remedy may be contained and means for expanding the tampon to correspondingly expand and fill the cavity and to maintain the remedy or medication in contact with the part to be treated.

HOP PICKING BASKET.—No. 786,487. April 4, 1905. F. W. Craver, Santa Rosa, Cal. This invention consists in a containing basket comprising an exterior trussed wire frame with top and bottom rings to which said frame is united, transverse wires fixed across the bottom ring, an interior flexible portion having a bottom to rest upon said transverse supports, an interior ring by which the bottom is extended means for connecting said ring with the bottom ring of the frame, and means by which the upper portion of the fabric is extended and connected with the top ring of the frame.

PIANO CHAIRS.—No. 786,484. April 4, 1905. Mary C. Carrick, San Francisco, Cal. This invention relates to an attachment for chairs and like supports which are used by piano and musical instrument players, and its object is to provide an adjustable support for the back and a means for supporting music therefrom when performers are playing together, and also a means for holding music which is not in use. It consists in a piano or like chair, of a channeled guide having its upper surface substantially flush with and transverse to the seat, a slide movable in the guide and a vertically disposed guide carried by the slide, an independent back having a slide movable in said vertical guide, and means for locking both slides in their guides.

STAMP MILL.—No. 786,590. April 4, 1905. A. McCombie, Grass Valley, Cal. One-half assigned to James McCombie, Chicago, Ill. This invention comprises in a stamp mill vertically guided reciprocating stamps, a crank shaft, flexible ropes connecting with the cranks and turnable connections upon the stamp stems, ratchets through which the stems are slidable and feathers turnably connecting the stems and ratchets, spring-pressed pawls engaging the ratchet teeth, a fulcrumed lever upon which said pawls are pivoted, a second fulcrumed lever, means engaging the two levers, a cam carried by the crank shaft with which cam the lever engages, and by the movement of which the pawls alternately engage and move the ratchets. This improvement is designed to reduce the frictional resistance and increase the rapidity with which the stamps may be reciprocated.

AN excellent leveling instrument may be made from three pieces of 1x4 lumber, or even lighter, arranging them in the form of the letter "A," giving the legs a broad base. A good height is 5 or 6 feet with a base of 10 or 12 feet. A plummet is suspended by a fine wire from a notch cut at the apex of the "triangle," as it is usually called. The instrument is placed on level ground, or on a floor, and the point indicated by the plumb line is marked on the cross bar. The bar may then be carefully marked for varying grades by placing a small block under one leg, say 1 inch thick, and the point marked on the horizontal bar. When in use one man holds the frame and another lifts the front end until the plumb line coincides with the mark at the point determined as the proper gradient, and a peg is driven there. The rear end is then placed where the front end had ditched and the second peg driven. By this means a ditch or tramway grade may be quickly and accurately established.

## Dredging for Gold.

Ever since the first attempt to dredge for gold in California this class of mining has attracted a great deal of attention. Before dredging was introduced into California, or elsewhere in the United States, dredgers were in what was at that time considered successful operation in New Zealand, but the dredgers of that time (prior to 1887) could scarcely be compared to the great machines in use in California, Idaho, Colorado and other Western States to-day, for either capacity or efficiency. The first dredger operated in California was at the Lambing mine, near Lone, in Amador county. It was a dredger provided with what is known as the "orange peel" bucket, the machine consisting of a single bucket of four segments. This dredger was successfully operated during the summer of 1887 at the place indicated, and produced from \$8000 to \$12,000 per month. The crew consisted of twenty-five to thirty white men and a larger number of Chinamen, working two shifts. The capacity of the bucket was 2 cubic yards. This dredger operated to a depth of 30 feet, the depth to bedrock. The machinery was housed and the entire outfit was shifted about on heavy sills in much the same manner that a house is moved along the streets of a city. This dredger was considered efficient in its day, but would make a poor economic showing by the side of the modern machines costing \$75,000 or more each, several of which are illustrated on this page. Elsewhere herein is a description of the modern dredger, with much of the detail of its construction and operation. Prior to the introduction of any type of mechanical dredger for gold mining, suction pumps were tried at many places in California, Montana, Dakota, Colorado, and in other mining regions, and one of the first type of dredger was a suction arrangement, but these devices, depending upon suction pumps alone, have not as yet found extended use where coarse material had to be handled. A later and more successful device was the hydraulic ejector, or elevator, many of which have been introduced throughout the placer mining regions of the West, and which have been found particularly useful where the gravel bed was below the drainage level.

THE reason some capitalists profess to prefer low-grade mines to those producing high-grade ores is due to the fact that ordinarily high-grade ores do not occur as great masses or broad veins, but are more restricted as to size. It does not necessarily follow that small veins are always high grade, for many veins of small or moderate size are also sufficiently low in value to satisfy the most exacting. It

A Modern Dredger Under Construction. (See Page 252.)

Breaking the Surface With a Modern Dredger. (See Page 252.)

Bucket Dredger, Showing Method of Stacking Tailings. (See Page 252.)

is due largely to the fact that such mines as those of the Homestake group and the Alaska-Treadwell mines, which produce low-grade ores, have made a long continued success, extending over a period of twenty to thirty years, that low-grade mines have come to be looked upon as offering less risk to the investor, with long-continued output and consequent possible profit. In the history of such mines there are usually many changes, and, as the mine workings go deeper, the expense is naturally expected to increase; but in the case of the Homestake it has actually been decreased. Mining and milling are accomplished there at considerably less expense per ton than in earlier years. This is due to improved machinery and methods in all branches of both mining and metallurgy.

## Copper and the Market.

The output of Lake Superior copper mines is now 19,300,000 pounds per month, or over 230,000,000 pounds per annum, with the probability of an increase from new development now in progress. At present the output of that noted district is nearly one-third of the entire production of the United States. Arizona's production is close to 200,000,000 pounds, with every indication of being maintained for a time, if not increased, for there are still large undeveloped copper resources in Arizona, and as the older mines are exhausted new ones may be expected to take their place, thus maintaining the output. With copper at the present price there is an additional incentive to open and equip new mines at points distant from the railroad, but which would quickly be provided with railroad transportation when the value of the mines justified it. Montana leads in the copper production, the output of that State being now about 310,000,000 pounds annually, chiefly from Butte mines. Mexico's production is at present over 100,000,000 pounds annually and is increasing. The other most important copper producing countries are Chili, Japan, Australia and Germany. The market is controlled by the Amalgamated Copper Co. and the Calumet & Hecla Co. Copper slowly advanced during the latter part of 1904 from 12½ cents to 15 cents and a fraction, at which latter price it now stands. The demand for the metal is strong and actually increasing, and while certain copper mining stocks have doubtless exaggerated market values at this time, a drop in stock does not necessarily indicate a drop in metal prices. Every copper producer is anxious to see the price maintained, and nothing but market manipulation is likely to lower the price of the metal, whatever may have happened to copper mining stocks. For the past ten years the production of copper in the United States has increased steadily. Within that time Arizona's production has increased from 38,000,000 pounds per annum in 1894 to over 170,000,000 pounds in 1904. The Lake Superior district in 1894 produced something over 100,000,000 pounds. Since then the output has annually grown larger, with the exception of 1899, 1900 and 1901,

when there was a temporary halt in the increase, but with a more marked increase in 1902, 1903 and 1904. Montana has steadily increased from 160,000,000 pounds in 1894 to 280,000,000 pounds in 1904, with every promise of a large increase for 1905. This indicates that there has been a steadily increasing demand for copper during the past decade, which no fluctuations of the stock market has influenced. If the demand did not absorb the supply in this manner there would be millions of pounds of copper on hand, but such is not the case. Consequently the market promises to remain firm at present prices, or near them, and any fall in the price of the metal can only be temporary at most. This is clearly indicated by the official report, issued April 3, to the effect that the world's total visible supply was only 16,745 tons.

## The Need of Careful Investigation.

The frequency with which mistakes are made in the premature installations of mining and metallurgical plants, particularly of the latter, is a matter of constant surprise in the light of the experience which this age affords. This is emphasized in an article appearing elsewhere herein under the title of "Place and Value of Small-Scale Ore Tests," wherein the author advises the thorough testing of small amounts of ore to first determine its character and the proper method of its beneficiation, and then the construction of a unit plant of full size, complete in detail, and the demonstration, on a commercial scale, of the process evolved by laboratory experiment. The wisdom of this advice cannot be doubted, as is too often shown in idle mills and reduction works built at great cost, but wholly unsuited to the treatment of the ore of the mine for which they were built. Formerly, when metallurgy was not in so advanced a stage as at present, there could usually be found an excuse for such premature installations, but not so in these days, and yet, these occurrences, by courtesy called mistakes, are not infrequent. Over twenty years ago an Eastern company operating in the Black Hills of South Dakota expended many thousands of dollars in the attempt to work the rebellious telluride ores of the Bald Mountain district. A 20-stamp mill was built. It was unable to give capacity and at the same time crush the ore fine enough, and the stamps were taken out, the mill remodeled and half a dozen pulverizers, of a popular type in those days, were installed. These proved of little use, and were in turn rejected and the twenty stamps replaced. These were then supplemented with six large grinding pans, similar to the pans in silver mills. These required a largely increased power, which was provided. Still the ore was refractory to every method tried—chiefly various kinds of amalgamation. Chlorination was suggested, but rejected as too expensive. The stamps were again torn out and a new type of pulverizer—rolls was tried. This was no more successful than the other devices, and the company, at last discouraged, gave up the effort and waited for science to seek out a method in the coming years. These repeated endeavor to treat refractory ores were certainly deserving of greater success than attended these efforts. The only regret which the company could entertain should be that the tests were not made on a less elaborate scale, for in each instance a mill was built that should have been capable of treating at least fifty tons daily, when the same knowledge might have been gained with a 1-stamp battery or a single pulverizer. These ores are now successfully treated by cyanidation or chlorination, for they are no more amenable to amalgamation to-day than they were at that time. Even to-day may be seen similar honest effort wasted in the endeavor to work out a metallurgical process which will successfully treat a refractory ore, appearing in the shape of a large, fully equipped plant, when it is not known that the process and the machinery are adapted to the ore. Make the small tests first, and when the laboratory experiments have demonstrated the probable adaptation of a certain line of treatment to the ore, it will be time enough to build a full-sized unit plant to prove that the intended process will do what the experimenter thinks it will. Having demonstrated this fact, it will then be the proper time to put in a plant of a size and capacity commensurate with the possibilities of the mine to supply ore continuously.

IN the history of mining there have been many very strange and unexpected changes. The one-time lead mines of Missouri are now producing almost exclusively zinc ores. The Horn Silver mine of Utah was at one time a large silver-lead producer, but now ships large amounts of copper ore. The great copper mines of Butte, Montana, were originally worked exclusively for gold, and later for gold and silver. The Mount Morgan mine of Queensland, Australia, produced originally gold only, but within the past two years it has become a producer of considerable copper. The tin mines of Cornwall were originally mostly worked as copper mines. The great silver mines of Cerro de Pasco in Peru are to-day being equipped for the production of copper and promise to become an important factor in the copper world. Leadville, Colo., was originally a gold-producing placer camp. In 1877 it began its famous production as a lead-silver district, and to-day it produces gold, silver, lead, copper and zinc. The Bingham district of Utah was at one time a gold-silver camp. Its production is now largely copper, gold and silver. Twenty years ago some prophesied that the Homestake mine at Lead, South Dakota, would in depth become a silver mine, but at its present depth of 1200 feet there is no evidence of this anticipated change. The early miners in the Cœur d'Alenes of Idaho gave scant attention to the lead-silver ores which have since become such an important factor in the lead market of the world, and which have sustained the camps in that district and permitted the founding of an enduring industry. Instances of these changes might be multiplied almost indefinitely, but a sufficient number of cases have been cited to show that any district may anticipate radical changes from the conditions originally obtaining in them.

THE Dolcoath tin mine is one of the oldest mining properties in England. It has produced a large amount of tin and also of copper. In the treatment of the ores of this famous old mine there has always been what has been looked upon as an unavoidable loss in ore dressing, particularly in the slimes. Recent experiments made there indicate that from now on these slimes will be successfully treated, and the ore contained in them saved. This is merely illustrative of the progress of the times which has invaded even conservative Cornwall. It seems strange when it is considered how much the mining world at large owes to the experiences gained in Cornish mines that the managers of these mines should be so slow to adopt in their mines and metallurgical establishments the machinery and methods so successfully applied elsewhere. Wherever on earth mining is done, there will be found expert Cornish miners, and some of the most satisfactory methods in both mining and metallurgy in common use throughout the world had their origin in the Cornish tin and copper mines, still the Cornishman at home is ultra conservative and usually slow to pattern after his more progressive brothers who are working mines elsewhere.

SO vigorously have old tailings piles from gold mills been bought by cyanide operators during the past ten years that there now seems but few accumulations of tailings remaining untreated that will afford a profit. Many such piles of mill refuse have added millions in gold to the wealth of the world, and in many instances also incidentally to the pockets of the operators, but many, also, have failed to yield the anticipated profit. In some cases these ventures have failed to pay for the plant built to treat the material. Cyaniding is at present almost wholly confined to the treatment of sands and slimes coming direct from the mills. So eagerly have the old tailings piles been looked up that in a number of instances the more bold or less experienced cyanide men have undertaken the task of treating the tailings from silver mills, but up to this time these ventures have not proven successful, except in rare instances, where there was also a considerable amount of gold associated with the silver. The extraction on these silver tailings is usually less than 60%, and in many cases much lower than this. It may be anticipated, however, that further improvements will be made in the process which will make the silver tailings and ores cheaply amenable to some modification of the process, which in the past has already undergone numerous changes for the better.

## CONCENTRATES.

By refractory ore is meant ore which is difficult of treatment. It was originally applied to any gold-bearing ore which could not be successfully amalgamated.

THE chief advantages of steel over iron are its greater elasticity and the property which permits it to be hardened by tempering to almost any degree of hardness.

AN acre of ground is 208.71 feet square and contains 43,560 square feet. A reservoir covering one square acre would contain for each inch of water it held in depth 27,154.291 U. S. gallons.

WHERE substantial mine tracks are required good sized ties must be properly laid, and the rails spiked down. Fish plates are not absolutely necessary, though often used on outside tracks.

PULLEYS should be so run and belted that the slack of the belt shall be on top. This causes the belt to have a greater surface contact on both pulleys, with consequent greater transmission of power.

NO LAW was passed by the last California Legislature requiring that a corporation (mining or otherwise) should own the property in fee before it could issue stock and sell the same to the public.

CAR and skip wheel axles should be of round bars of cold rolled steel. If the ends become worn the bar may be cut in the center, the outer ends welded and the wheels placed on the newly formed ends.

TO ascertain the number of revolutions a pulley will make when belted to another pulley, or flywheel, multiply the number of revolutions of the driving wheel by its diameter in inches and divide by the diameter of the driven pulley.

GOOD tests for zinc blende are the color of its streak or powder, always grayish to brownish, and a drop or two of hydrochloric acid on zinc blende evolves sulphuretted hydrogen ( $H_2S$ ), which may at once be detected by its odor.

THE rails used in mine tracks usually weigh twelve to sixteen pounds per yard. These rails are of variable length, but are generally about 20 feet long. Longer rails are difficult to handle in many mines owing to lack of room at the stations.

THE tonnage of country rock extracted in mining work may usually be estimated on the basis of 13 cubic feet per ton removed. Each lineal foot of a drift 8x5 feet clear will produce about three tons of rock. This varies slightly in different rocks.

NATIVE silver is frequently found associated with copper in a gangue of calcite in the upper levels of some of the Lake Superior copper mines. Neither of the metals is alloyed with the other, both being in a state of unusual purity. No gold is known to occur in these ores.

PRIOR to May 10, 1872, when the present Federal mining laws became effective, there were certain local districts where the lode locations were square and no extralateral right attached, the locator being confined to the planes of his surface boundaries drawn downward vertically.

AS a record of hoisting, the No. 1 coal mine at Doukville, Ill., recently hoisted 2928 tons of coal in eight hours. There are no metal mines doing anything approaching this, and few coal mines. At Kimberley, it is said as much as 8000 tons have been hoisted from a depth of 1500 feet in twenty-four hours.

COPPER MATTE is an artificial sulphide of copper and iron which usually contains gold and silver, and sometimes antimony, lead, zinc, bismuth and other metals. To determine the value of the matte the amount of each of the metals present must be determined, though the gold and silver are usually of the most importance, after the copper.

IN the desert regions water can be maintained at an agreeable temperature, by keeping it in a canvas sack, hung in the shade and open to the free circulation of the air. The temperature of the water is usually several degrees lower than the temperature of the surrounding air, due to the rapid evaporation of the water on the outside of the sack.

IN some quartz mills having flat bottomed ore bins it is the practice to keep the bottoms covered with a sloping floor of waste, just sufficient to allow the ore to run to the chutes without mingling with the waste. This protects the bottom of the bin, but seems to have no other advantage other than aiding in giving the mill structure steadiness, by reason of weight.

SECTION 8 of the mining law of May 10, 1872, contains the following: "Where a patent shall be issued for claims on unsurveyed lands, the Surveyor-General, in

extending the surveys, shall adjust the same to the boundaries of such patented claim, according to the plat or description thereof, but so as in no case to interfere with, or change the location of, any such patented claim.

THE solid matter in ocean water is 2139 grains per gallon, and that in the Dead Sea about 19,700 grains per gallon. The amount of saline and other soluble material held in solution in salt lakes varies with the rainfall, some years it being greater than others. In stages of low water the quantity per gallon increases, and in stages of high water following heavy rains it becomes less.

WHERE the track admits of it, a larger skip may be used in a shaft by placing the wheels on lugs bolted to the sides than by having them on axes passing underneath the skip. The former allows the skip to sink to the level of the rails, and even below them, where the rails are placed on longitudinal stringers, as is often done, particularly where strap rails, instead of T rails, are used.

SILLS, posts and other woodwork placed in contact with the ground may be given a longer life and kept from decay by covering them with a coating of cement, the covering being held in place by a wire netting wrapped around the timber, being kept away from the timber by small wooden blocks. Poles thus prepared have been in use to support electric wires in Europe for several years, and have proven satisfactory.

THE conditions which insure a steady and abundant flow of water in mountain streams is not so much heavy rainfall as a heavy snowfall in the mountains, and for the best results it is the snow which falls in the early part of winter, and which becomes hard and compact during the winter season by successive rain and snowfalls until it is almost a mass of ice rather than snow. This melts slowly and maintains the summer supply.

FOR the purpose of comparison, a "volt" of electricity is sometimes likened to 1-foot head of water, and the volume of flowing water is sometimes compared to current of electricity, the unit of current being the ampere. The comparison is not absolute, for it merely indicates, in a general way, the similarity of the electric current and a stream of water flowing through a pipe. If the comparison be carried too far it is likely to lead into error.

BY "ore-in-place" is meant ore which occurs within walls of solid rock—not a placer. In some mines the rocks near the surface are soft and easily dug with pick and shovel, or by sluicing, hydraulicking, etc., such as some of the so-called seam diggings. Although often these mines are worked to considerable depth in the same manner as placers, the deposits of this character are rock in place, and subject to location under the lode claim laws.

IN running a tunnel where it is the intention to make it of large size it is often wise to first run a tunnel of smaller section, which may later be enlarged when it becomes necessary. Large tunnels are often run for mining purposes the size of which is not justified by the available ore, or other economic conditions. Tunnels of small cross section usually cost more per cubic yard extracted than in large ones.

THE crank pin and crosshead of an engine do not travel at the same rate throughout a revolution of the crank shaft. The crank pin travels at a constant speed, but the crosshead is constantly traveling at an accelerating or diminishing speed throughout the forward and backward stroke, coming to practically an absolute but only momentary standstill at either end, the duration of rest being so small that it is claimed by some that the crosshead does not actually stop at all.

IN building a trestle to carry ore trains of ordinary size it is not necessary to use heavy timbers such as are ordinarily employed in building railway trestles. A firm and safe trestle may be made of 2x6 or 2x8 lumber by building up legs, using two pieces of the timber and separating them by cross braces, either horizontal or inclined, or both, depending on the height of the trestle. Such a structure may be safely carried to a height of 30 feet, or more, with no stick larger than 2x8 inches.

WHERE a locator has taken a placer claim adjoining a senior placer claim, located prior to July 9, 1870, the boundaries of which did not conform to the Government survey (which under that law was not essential), the law provides that "where placer claims cannot be conformed to legal subdivisions, survey and plat shall be made as unsurveyed lands." Sec. 10, Act of 1870, amended by mining act of 1872. The fractional claim lying between the old claim of 1870, and the land survey line in the vicinity, which claim constitutes a fractional claim (less than twenty acres) may be located as such fractional claim, having the land survey lines, and the lines of the prior claim as boundaries. This fraction is subject to the requirements of the law the same as full claims.

ONE of the most frequent causes of boiler explosion is the sudden entry of cold water into a highly-heated boiler in which the water is at a low stage. The rapid expansion of the newly created steam raises the pressure to the point of resistance of the boiler or beyond it.

When it is discovered that the water gauges show no water, the fire should be immediately drawn, if not a heavy one. If the fire be a large one, cover it with wet ashes at once. Either of those expedients will have the effect of lowering the temperature to a point where it will be safe to turn water into the boiler again. In boilers a large part of the mineral and other matter in the water which make scale if allowed to remain rises to the surface when the water reaches the boiling point, and it may then be blown out by opening the surface blow-off cock. This disposes of the foreign matter before it has the chance to form scale.

A WATER-TIGHT DAM may be constructed in the level of a mine of concrete by using board moulds in the usual manner of building concrete walls. It will be necessary to leave a manhole through which the workmen may pass out after having completed the dam, the top portion being finished from the inner side. The dam must be built into channels cut in the rock—in the floor, sides and roof of the drift—and it would be a wise precaution to reinforce it by the use of iron or steel bars like pieces of railway iron. The manhole should be closed by a steel plate provided with a suitable gasket. It is usual to also place a water pipe, securely anchored, in the lower part of the dam, and to provide the pipe with a valve, to control the flow of water. By placing a pressure gauge on the outside of the dam, and between it and the valve, the water pressure and consequently static head may be determined, but this gives no idea of the volume of water backed up behind the dam.

THE transfer of alignment of mining work down a shaft is one of the most difficult and delicate operations the engineer has to perform, and the deeper the shaft and the longer the line of connection with the other workings the more care required. He must determine the direction and elevation of a line which may be several thousand feet in length, by a base line which at most can not be longer than the length of the shaft. This being the case, the need of extreme accuracy in determining the direction between two points in the shaft is apparent. Various expedients are resorted to in this class of engineering, but the most common practice in the case of vertical shafts is to lower two heavy plumb-bobs from fixed points at the surface to within a few inches of the bottom of the shaft. For this purpose various sized weights are used, from 50 pounds to as high as 250 pounds. Lead is preferable to iron, as the specific gravity of lead is greater, and a bob of given weight takes up less space. Piano wire is generally used in this class of work, and the bobs are allowed to swing freely in a tub of some liquid, usually molasses, crude oil and sometimes water. In doing work of this kind it is very necessary that air currents be reduced as far as possible, for it is known that these currents have the effect of causing the wires to vibrate sensibly. Some experiments made in one of the deep shafts of the Tamarack mine, near Houghton, Mich., showed that there was a discrepancy in the distance between two suspended wires at the surface and at the bottom of a shaft 4250 feet deep of about 0.11 foot. It was supposed to be due to air currents. The wire used was No. 24 piano wire. In inclined shafts and those of irregular dip, and not having straight alignment, the difficulties are multiplied.

THE scorification assay is well adapted to the high-grade ores, and particularly those rich in silver sulphide. The reagents employed are pure granulated lead and borax glass. The lead forms an alloy with the precious metals of the charge, that portion of the lead which is oxidized combining with the borax and impurities and gangue of the ore to form a slag. The amount of lead and borax varies with the character of the ore treated. In a quartz ore no borax glass need be added. It is customary to take one-fifth assay ton of ore and forty to fifty grams of lead. The ore is mixed with half the lead and placed in the scorifier, the balance of the lead being spread over the top of the mixture. On top of this are placed two or three small lumps of borax glass the size of a pea. In scorification there are four stages to the operation—melting, roasting, fusion and scorification. A high heat is at first applied, which melts the lead. The ore rises to the surface and floats on the molten lead. In this condition the ore is roasted by a somewhat lower heat, by opening the muffle. The roasting continues until no more fumes appear, and the ore has settled into the lead. The heat is then raised and all the material fused. When fusion is complete pure white fumes come from the charge, the slag encircles the molten lead and brilliant colors play over its surface. It is here that the borax glass performs its most important function in making a fluid slag. If no borax were added to the charge, where much gangue is present, the slag is likely to float in detached masses on the lead and give some trouble. When the fusion has been completed the heat is lowered until the ring of slag spreads out and finally covers the lead. The heat is then again raised to make the slag more liquid, so that any particles of lead inclosed within it may separate and go to the main mass below. The scorifier may then be removed from the furnace, and either poured or allowed to cool. The button should be hammered in the usual manner. It should be soft, malleable and not weigh over 12 or 13 grams. The scorification assay, while taking less trouble in preparation than the crucible assay, requires more skill and careful attention than the latter. If the lead button is too large for convenient cupellation scorify with some borax glass until reduced to proper size.

## South African Methods.\*

NUMBER II—CONCLUDED.

Written by THOMAS H. LEGGETT.

**WATER.**—It is a well-known fact that the mines of the Rand have very little water to contend with. It is very fortunate that this is so, since the average yield of the seventy to eighty producing mines for the last few years has only been 41 shillings per ton, or, say, \$10. It is evident that this grade of ore would not permit the handling of large quantities of water from great depths. The one mine that has been afflicted with a heavy inflow of water is the Knights Deep, where they raise from 1,000,000 to 1,250,000 gallons of water per day, from a depth of 1200 feet. They pump this in a single lift by means of electrically driven high-speed Riedler pumps, of which they have three in their underground station, each with a capacity of 450,000 gallons per day. It may be interesting to note that during the dry season on the Rand the water from this mine has been sold at such a rate as to more than cover the cost of pumping.

**TIMBER.**—This is a material required but very little in the underground workings; also a very fortunate thing for the deep-level work, as it would affect the mining costs very considerable. The hard quartzitic sandstone walls stand without either timber or filling being required, and only in a very few cases have any heavy falls of rock occurred in the now very extensive stopes. Prof. Agassiz, who visited the Rand in the early part of 1899, expressed the opinion that, after large areas of reef had been stoped out, or, say, in another five or ten years from now, extensive subsidences of the surface would take place, affecting the deep-level mines as well as the outcrop. Subsidences have already occurred in a couple of the outcrop mines, very close to the surface, and perhaps greater ones may yet occur in the outcrop area. But it is safe to say that this will only happen toward the end of the lives of the outcrop properties, and they can be readily foreseen and guarded against in such a manner that no valuable property on the surface need be damaged. That the surface of the deep-level areas will be seriously affected is, in my opinion, very doubtful, since the caving that may take place in these sedimentary strata will occur in the shape of falls of successive layers of rock, which will speedily fill up the worked-out area and uphold the remaining ground.

**WORKING COSTS.**—Unfortunately, I have not available here the official figures which would enable me to speak with accuracy, but one may say that, approximately, the working costs before the war were from 27 shillings to 28 shillings per ton, or, say, \$6.75 to \$7, while they are to-day about 2 shillings to 3 shillings per ton less, or, say, \$6.25 per ton. This, however, does not include the cost of obtaining Chinese laborers, which, I am given to understand, is very high. At the same time, the margin of profit is such and the scale of working is so great that these mines on the Rand are to-day paying out in dividends fully 30% of their total output; in fact, I have no doubt that this year they will exceed this proportion as they did in 1898, when the dividends paid were 32% of the total yield of £15,141,000, or nearly £5,000,000 paid out in dividends in one year.

**COAL.**—Some of the mines, especially those on the east sea flank, have both coal seams and gold reefs within their area. Coal mines have been developed in the immediate vicinity of Johannesburg, about 20 miles away, and also a higher grade coal, about 100 miles distant in the Middleburg district. This has enabled coal to be furnished to the mines at Johannesburg at an average price of \$3.50 a ton. At the western end of the Rand it sometimes runs up to \$4 and \$4.50; at the eastern end the price is nearer \$3. An electrical transmission plant was installed some ten years ago. It is a 20-mile transmission and a large plant with several 1500 H. P. units. It is built close to the coal mines, coal slack being used for fuel, the E. M. F. being 10,000 volts.

It has not replaced steam to any extent, however, on account of the cheapness of coal, and has been used chiefly as an accessory power in the cyanide and such lighter work, and for illuminating purposes in the town.

**DIAMOND MINING.**—There is little that I can tell you that is new about diamond mining in South Africa in view of the recent publication of an exhaustive treatise on the subject by that highest of authorities, Gardner Williams.

The first conception of a diamond mine in South Africa was that of an alluvial deposit, as the stones were found loose in the soil, and the laws were made on that basis. A claim was defined by law to be 30 feet square, and a man could take up but one claim only. It was soon found, however, that it was not an alluvial deposit, but a chimney or pipe in shape, more or less like an inverted truncated cone, on top of a cylinder. They finally struck at 500 or 600 feet depth the throat of the deposit, or the cylindrical portion, the area of which usually turned out to be anywhere from one-half to one-quarter the size of the

original area on the surface. Again, there was great confusion through one man working his 30-foot claim deeper than that of his neighbor, resulting in the ground caving upon him. Finally, from this and other causes, it became very clear that the deposit would have to be worked as a unit. They consolidated and formed the great De Beers mines of Kimberly, and then the work was laid out on a proper mining basis, with ample shafts sunk in the wall-rock, and open-work mining was stopped. Ever since, the mining has been carried on in that way, and to-day they handle several million loads per annum. At De Beers mine, the "load" is the unit of measurement, and is eight-tenths of a ton, or 16 cubic feet. The De Beers mine produces over £5,000,000 per annum and pays in dividends about £2,000,000, while it controls the diamond market of the world. Before the consolidation of the various owners of the claims, Kimberly considered itself ruined, because each one of the many diamond producers was throwing his product on the market and so breaking the price as to make diamond mining unprofitable. It, therefore, became very apparent that the diamond industry has to be handled as a unit, for financial reasons quite as well as for technical ones. Since that was done it has been remarkably successful. They are down now in the Kimberly mine, I think, something over 2000 feet, while the De Beers mine holds the record for rapid hoisting. In May, 1899, they hoisted at the De Beers mine 7409 tons from a depth of 1200 feet through two compartments with one engine, and since then they have beaten that record, which stands now at over 8000 tons hoisted in twenty-four hours by one engine through two compartments, from a depth of either 1400 or 1600 feet. As I am so far away from my main office I cannot give absolute figures.

As to the average yield of the diamond mines: I think the De Beers mine runs about 60 karats per 100 loads and the Kimberly about 75 karats per 100 loads, while the Premier, one of the famous mines, yields from 28 to 30 karats per 100 loads. But the Premier pays almost as well as the higher grade mines, because of the purity of its stones and the greater cheapness of working, it being still shallow and worked from the surface.

In the Transvaal they have discovered a diamond mine that is proving to be a very big one, namely, the Premier mine. Its area on the surface is a little over 3000 claims. The area of the Kimberly mine originally was something like 650 claims, and the area of the De Beers mine at Kimberly was in the neighborhood of 1400 claims, so this Premier diamond mine of the Transvaal has an area more than twice as big as the largest Kimberly mine.

As you know, the surface deposit, the top of the "pipe" or "chimney," is weathered, so that the material can be scraped up with scrapers and put at once into the pans. You can put up a hand-driven pan and get enough diamonds out of such a deposit to put up more elaborate machinery. Hence a diamond mine can be developed very rapidly and pay its way as it goes. This Premier mine is only two years old last month, and I have just extracted a few figures as to what has been accomplished there during that time:

YEAR ENDING OCTOBER 31, 1903.	
Washed.....	76,531 loads
Yield, at 27s 8d per karat.....	59,208 karats
Or, pounds sterling.....	137,435
Working costs.....	35,600
Profit, pounds sterling.....	101,835
YEAR ENDING OCTOBER 31, 1904.	
Washed.....	951,984 loads
Yield, at 27s per karat.....	653,040 karats
Or, pounds sterling.....	879,550
Working costs.....	154,697
Profit, pounds sterling.....	724,853

## The above results for 1904 give

Value.....	Per Karat.....	Value.....	Per Load.....
Expenses.....	27s 8d	Expenses.....	18s 5d
Profit.....	4s 9d	Profit.....	3s 3d
Or profit per karat.....	22s 3d	Or profit per load.....	15s 2d
Or profit per ton.....		Or profit per ton.....	\$5 50
Or profit per ton.....		Or profit per ton.....	3 70
Or profit per ton.....		Or profit per ton.....	4 60

These Premier diamonds do not bring as high a price as the Kimberly diamonds, which bring, I believe, about 42 shillings per karat. The run of stones in the Premier mine is not so good, as they average about 27 shillings per karat. The new plant now completed enables them to treat 110,000 loads, or 88,000 tons per month for the first nine months of the present year, and enlargements of plant now under way will permit of washing 200,000 loads, or 160,000 tons per month for the last three months of the year.

On the basis of the present yield of 75 karats per 100 loads, the present price of 27 shillings per karat and costs of 3 shillings per load, the profit for this year is estimated at £1,371,000 sterling.

This gives some idea of the rapidity with which a good diamond mine can be developed to even huge proportions.

On account of the surface dimensions of this weathered diamond-bearing rock, 3000 odd claims of 30 feet square each, they have so many million loads of ore in sight that they will not have to mine the "blue," or unweathered ground, through shafts for a good many years to come.

There is one interesting point in reference to diamond mining in the Transvaal, and that is the recently enacted diamond law. The government has taken 60% of every diamond mine discovered in the Transvaal, leaving the owners 40%. As a consequence of this profit of £1,371,375 which the Premier expects to make this coming year, the government will get £822,000.

This is a law that has been enacted since the advent of the new government and applies only to the Transvaal. The highest dividends paid by the gold mines was in 1898, amounting to £4,800,000. The government gold tax is 10% of the profits. This means £480,000 a year the government will get out of the Transvaal gold mines when they produce about £16,000,000 pounds as they did in 1898 and will do in 1904. Now, out of this single diamond mine, the Premier, last year, the government's share is £420,000, or almost as large an income as from all the gold mines of the country combined. I do not think it is too much to anticipate that inside of two years the income of the Transvaal government from this one diamond mine will far exceed the income of the 10% tax on profits from the entire gold mining industry.

In the matter of this 60%, the old law gave the discoverer of a diamond mine one-eighth of the area. That is to say, if a mine had 3000 claims he would be able to take one-eighth, or something near 400 claims. The public could then step in and locate all the additional area. In such case, however, they would have a repetition of the experience in Kimberly, namely, of breaking the diamond market again. The people would work this ground, which is easily washed, and the market would be flooded with diamonds. Therefore, the government took the attitude of saying: We will be the public to take these additional claims in order to prevent this disaster (and it was a great disaster in Kimberly, unquestionably), and we will satisfy the owners by giving them 40% of the mine instead of 12½%, reserving the balance for ourselves.

It was discussed for some time, a commission was appointed, and a number of us engineers were called before them to give technical advice. It was, however, finally passed that the government should have 60% of the diamond mine and of all future diamond discoveries. They allow the owners of the mine to deduct the cost of equipment, etc., and after that they share the profit. They thus prevent any flooding of the diamond market. It was pointed out by some of the witnesses before the commission that perhaps just as sound a way would be to give the owners the entire mine and let the government tax the output, the government to obtain in that way its necessary income. But that suggestion did not maintain, the law was finally passed and stands as described.

Unquestionably, the country has now gone through its most depressing period of reaction, such as follows every war. The labor difficulty having been satisfactorily solved, I look upon the future of the mining industry as very bright indeed. The gold product from now on will undoubtedly increase by leaps and bounds. I venture to predict that South Africa will head the list of gold-producing countries of the world next year and will retain that place for many years to come. Beside this great fact the minor difficulties just alluded to sink into insignificance.

## How to Set Up Wood Stave Tanks.

Written by R. STUART BROWNE.

The following interesting description of the methods of building and tearing down wood stave tanks is from the advance sheets of the new catalogue (now in press) of the Redwood Manufacturers' Co., 8 California St., San Francisco, Cal.:

First provide a substantial foundation. On this lay parallel sills from 12 to 24 inches apart, depending on the size of the tank, and cut so that they will come inside the chime without touching the staves. The staves must not be allowed to support any weight; consequently, the sills must be higher than that portion which projects below the bottom.

Lay the bottom on the sills, putting it together with dowel pins. The dowel pins are cut from the long round sticks, which are sent by the makers with the tanks. Each bottom plank is numbered and must be put in its proper place. When the bottom planks are unusually long, they are made in two or more pieces, the parts being joined together with iron tongues. After the bottom is laid, nail a cleat across it to hold it together, being careful not to drive the nails clear through the wood.

Drive the first stave in slightly at the crozing, the groove cut near the bottom of the stave, and stay it with a brace running from the top of the stave to the center of the tank bottom. Be careful in driving on the staves to use a block of wood between the staves and the hammer.

In putting up a tank, the most important thing to be observed is to put in a proper amount of stave material. The most frequent cause of leakage comes from making the tank too tight at the beginning. The redwood used in tanks is very dry, and when it takes up water it must have room to expand. If the

tank is too tight, the bottom planks will buckle and every joint will be strained. The secret of putting up a tank well is to know how to judge the amount of expansion in the wood. If not familiar with this class of work, be on the safe side and put the tank up so that the seams are not too tight. Each stave has boles bored for dowel-pins several inches from the top. This is of great assistance in bolding the staves in position while they are being set up.

It is very important that the hoops be placed on the tanks just where they are intended to be, and to make this easy the manufacturers have stenciled black lines across several of the staves. These staves should be distributed around the tank, in order that it may be seen plainly from every side just where each hoop goes.

In driving the staves on at the crozing, drive them on just as little as possible to have them hold, keeping them tight together, the object being to get as many staves on the bottom as possible. Rip and plane last stave to fill remaining space.

With the power of compression obtainable with round hoops, the staves can be compressed to almost any point desired after the bands are once around them. The top of the staves may overhang a little at the upper end for convenience in setting them up. After the staves are all on, they may be stayed temporarily with a rope, if in a windy place, using a stick to twist and tighten the rope; but in most cases it will not be necessary.

In putting the hoops on, begin at the bottom. To keep the hoop from slipping down while sections are being connected, drive short nails at intervals on the hoop lines to keep them in place until the hoop is drawn taut. This will not be necessary, however, if one man can be placed at each lug when a hoop is being put on. After the hoop is on, it is well to take a pencil and mark where one row of lugs should come. The lugs should be set in spiral rows around the tank, never having one lug immediately above another on the same stave. A spiral can be made very neatly by bending a thin strip of wood around the tank at an angle and then marking its position with a pencil. Where different lengths of rods are used in making up the hoops, be careful to get the same length of rod on the same side of tank, in order to make the lugs row up regularly. After the hoops are all on and drawn snug enough to hold them in place, one man should get on the inside of the tank with a mallet and block of wood and carefully drive flush any staves that show slightly sprung until the tank is nicely rounded. Should the staves spring back a little, tighten the bands.

Commence tightening the bands from the bottom up, working over each band until the top is reached. Do not try to draw too much at a time; the best results come from going over all the lugs several times, drawing each one a little. While one man is tightening up the hoops the first and second time, another should go around the tank with a bammer of, say, three or four pounds weight, striking the hoop firm blows every 3 or 4 inches, to help the band to bend in and get a good bearing. When a tank is finished, all the hoops should be drawn up equally tight. It is well to go over the hoops each day for two or three days, and it will be found that they can be tightened a little. In hot, severe climates this may be necessary occasionally, until the lumber in the tank has become as dry as the climate, and then the tank will remain tight.

**DIRECTIONS FOR TAKING DOWN AND RESETTNG TANKS.**—The taking down and resetting of an old tank is much more difficult than the setting of a new tank. First with a piece of chalk go around the tank and number the staves in the order in which they occur and likewise number the bottom planks. Then gradually loosen up the nuts on the hoops from top to bottom. Then, beginning with the top hoop, drop them off. Tie together portions comprising each hoop.

With a bammer, and block to protect the wood, knock off the last numbered stave from the inside down near the bottom. Nail a short cleat along the edge flush against stave No. 1, so that when the staves are put back the position of No. 1 can be readily determined. Now knock off the rest of the staves in regular order and tie them in bundles. One man should hold the stave while the second man is driving it out. Unless this is done the stave is apt to fall over and split off the chime.

Drive the bottom planks apart by means of a broad iron wedge, such as an ax bit, inserted in the cracks some distance from the rim. It is best to use two or three wedges, and they must be tapped very gently. The putting together of the bottom again is an easy matter. The getting in of all the staves without trimming the last one is the problem. If the last stave is trimmed, the tank is pretty sure to leak. The secret of getting in the last stave consists in putting the bottom together loosely, so that it has a larger circumference than when it was taken down. Therefore, leave some good-sized cracks in the bottom. Commence with stave No. 1, placing it against the cleat nailed along the edge, and follow with the other staves in regular order, making them fit as close as possible. If the work is done properly, the last stave will fit in. If it don't, the bottom must be spread until it does. Now replace the hoops; tighten up and the bottom and sides will draw together tightly as before.

## Place and Value of Small Scale Ore Tests.\*

Written by ERNEST H. SIMONDS.

The problems which confront the miner and producer of precious metals are more numerous and diversified, if not also more complex and difficult, than are the problems which confront most other classes of business men; and for their correct solution not only the results of scientific investigation, but, especially, the methods by which these results are obtained are of the greatest value. Progressiveness, an eagerness to investigate, a knowledge of the results of scientific progress and ability to make use of them are more valuable to anyone in our pursuit than in almost any other. The miner has the same problems of management as those of every business man, to which are added the problems of engineering; but, besides, he has to deal with problems of geological structure and of the metallurgical treatment of his ore, the correct solution of which is generally vital to the success of the whole enterprise; and one problem or the other is often more difficult to solve than any problem of engineering or of management. Moreover, if we seek the points in the management of a mine where the largest losses of profits are likely to occur, we shall find them, first, in the expense of useless dead work in developing the ore, and secondly, in preventable losses of values in the tailings. Here the largest economies are possible and here the largest successes are achieved. Again and again, a clear insight, not before obtained, into the manner of occurrence of ore bodies in relation to the surrounding rocks or of the condition of the valuable metals in the ore in relation to the other minerals present has turned failure into brilliant success.

The first requirement for the certain attainment of desired results is a complete and accurate knowledge of ascertainable facts, that is, full and accurate data. In order to make clear the place of small scale tests in obtaining data in relation to other methods of testing, let us first see what other methods are available.

There are three general methods of making ore tests which are used by different persons and under different conditions, each of which has both advantages and disadvantages. These three methods are:

1. By working a parcel of the ore in a mill of a neighboring mine.
2. By sending a carload or less of the ore to be worked to a metallurgical laboratory or testing works, accurate samples and weights being obtained of the ore and products of the test.
3. By making small scale tests in the laboratory, followed by the erection (before the entire plant is built, and the experimental operation at the mine, for as long as may be necessary to work out the precise details) of one complete unit.

Let us consider in some detail the advantages and disadvantages of each of the three methods.

1. The first method, by working in a local mill, is a cheap one, since the value extracted will help to pay for the work; and this method yields useful confirmatory results in cases where it turns out that the ore is similar to the other ores of a district which are being treated successfully. If sufficient ore is milled, as can easily be done in such a test, to get the plates into good condition and the machinery working well and to obtain enough bullion and concentrates so that unavoidable errors in the cleanup have only a small influence on results, the results may be quite conclusive. An instance of this was when one of the mills of the Jackson, Cal., district was used to test the ore of another mine a mile away, which was being reopened, before the latter's mill was built. But if it prove that the old mill is not adapted for treating the ore undergoing test, it may give little information as to what method may be used with success. For example, had the Black Oak ore, at Soulsbyville, Cal., been tested in a mill at Tuttletown, Cal., the owners would have learned simply that the ore was not free with coarse crushing and would have received little help towards working it with the high degree of success which they have now attained. Another circumstance adverse to the first method is that the local millmen are apt to be biased in favor of the method they are using and perhaps have little knowledge of methods used with varying ores and in other districts.

2. The second method, by working a carload or less at a testing works, has decided advantages over the first in that facilities will be provided for getting exact samples and weights and that the test probably will be conducted by men with a somewhat wide knowledge of methods of ore treatment; and in that the machinery will be provided with means of adjustment so that its operation can be more nearly suited to the particular ore. However, the rapid progress in methods and machinery for the treatment of gold and silver ores renders it impossible that any plant should be equipped with machinery for testing all methods or that its machinery will not before long get behind the times. Assuming, however, that the testing works is equipped with the machinery best adapted to the ore, the difficulties of

such tests are: First, the tendency is to send an insufficient amount of ore, or what is sent is not the average output of the mine, which the mill to be built later on will have to treat; secondly, that a considerable portion of the ore used for the test must have been milled before the machinery can be properly adjusted to enable nearly as good a recovery to be extracted as is possible; and, thirdly, a good deal of labor and care is required in a perfect cleanup—indeed, in tests by plate amalgamation, accuracy in the cleanup is practically impossible.

3. The third method, by making small scale tests in the laboratory, followed by the erection and experimental operation at the mine of only one complete unit of the plant, but this of full working size, has the disadvantages as compared with the first and second methods that the owners must go to the expense of the purchase of a unit of the plant, for its transportation to the mine and for its erection in working order there, before any of the ore has been actually treated on a working scale by the machinery intended to be employed. It has the further disadvantages that the mill will not be treating its full output so soon and that it will cost somewhat more to erect first one unit and later to erect the rest than to install the complete mill at once.

But the disadvantages of the third method, above enumerated, are heavily outweighed by its advantages, which are numerous and important. Assuming for the present what will be discussed later, that complete laboratory tests by competent men will correctly indicate the most advantageous process or combination of processes, for example, whether amalgamation, concentration, leaching or smelting, or a combination of two or more of these, is required, and what form of the one decided upon is best, whether the ore must be roasted, etc., it is possible, from the data of such tests, to erect at once at the mine a plant of full working size adapted to the ore, except perhaps as regards details, but so nearly the best possible plant that it can be made such by simple, inexpensive alterations which can be effected on the ground. The one-unit plant can then be used as a testing works, in the same way as would a neighboring mill or a general metallurgical laboratory, to determine with precision extractions, costs and details of operation and to expose in working any faults of mechanical construction, should they exist, so that they can be corrected in the one-unit and avoided in the complete mill to be erected later. Plans for the complete mill should be drawn before the unit is erected, and the unit built in accordance with them.

The one-unit plant, for purposes of testing, has all the advantages and none of the disadvantages of either a neighboring mill or a public ore-testing works and has other advantages peculiarly its own. Its advantages over other methods may be grouped under four heads: 1, ore supply; 2, modern machinery; 3, full working scale; 4, economic or business reasons.

1. There is an abundant supply of ore to be had for the cost of mining it; and conditions will enforce, or at least facilitate, the use of ore for test that correctly represents, in grade and in quality, the average character and the different phases of the ore from which the complete mill will later on be expected to obtain the highest extraction at the least expense and with the smallest investment of capital.

2. The machinery will be of a type best adapted to the ore, as indicated by the preceding laboratory tests, and it will be of the very latest design, since it is newly erected (the latter a condition of great importance in this day of the rapid evolution and improvement of metallurgical machinery), in respect, especially, of capacity and the accurate performance of the work in hand.

3. The process is not only adapted to the ore and the machinery up to date, but it is full working size, in fact, the complete mill will only be a multiplication of this single unit, thus testing the process and machinery mechanically and giving a chance for remedying any mechanical defects which may develop. Most testing works are equipped only with light machinery, and old mills have not the substantial construction and improved design to give large capacity, which in a great measure determines cost. With the unit plant right at the mine, tests of large tonnages extending over days or weeks can be made, thus rendering the small errors in the cleanup of slight effect on the results and giving exact data as to extractions, costs and even as to wear and tear; and the millmen have an opportunity to acquire skill in applying the method to the ore and in adjusting the machinery.

4. It enables the owners to realize on the ore taken from development workings with least expense and at once thus paying, at least in part, the cost of development; and the metallurgical development goes along with the mining development, problems of treating the ore are being solved at the same time as are those of finding and mining it. This is too frequently not done; no doubt you can call to mind at once, as I did within half a minute, from your own experience, three or four mines where ore of rich milling grade was proven in quantity several years before it could be worked to a reasonable extraction. Furthermore, if only one unit of the plant is erected at first, the temptation will be removed, in fact it will be impossible, to work through the mill (and

\*Trans. Cal. Min. Assn.

largely down the canyon or at least into the tailings pond, or perhaps into the treasury of the railroad company) the values in the rich ore usually taken from a new mine, before possible difficulties in its treatment have been gotten over. Such education is too expensive; it is cheaper to get it in a one-unit plant.

For all of these reasons, therefore, our final test can best be made in a one-unit plant at the mine. But in arriving at this conclusion, we have made one assumption, namely, that laboratory tests will correctly indicate the most advantageous process in a general way and with enough particularity so that we can install the machinery best adapted to the ore for the unit plant. We must, therefore, consider how far reliance may be placed upon the data obtained in small scale tests in directing us to the choice of the correct type of plant. How far are they reliable as preliminary tests? What are their faults? What their advantages?

(TO BE CONTINUED.)

### The "A" Frame Battery.

TO THE EDITOR:—I noticed an article in the *Mines and Minerals* some time since written by R. W. Barrell, E. M., which contained some very interesting data regarding the "A" battery frame for stamp mills, which he says first came under his observation in the early seventies at the Father De Smet mill in the Black Hills, and as I happen to know something of its origin, and how it probably reached that locality, I have thought fit to give an account of it.

The description of the construction of the "A" frame battery above referred to is as follows:

The mortar block, with mud and streak sills, are laid in a similar manner to those of the vertical post frame in general use about the country. In this particular case, the pit for the block was blasted out of rock for the last 8 feet of its depth. The size of the block put in was 4 feet 9 inches long by 30 inches wide by 14 feet in depth. We selected tamarack as being the best lumber in that part of Ontario, from which to obtain an even grade of 2-inch plank to satisfactorily withstand the jarring and vibration of the stamps, as well as lasting well in such a situation. After the 8-foot hole was blasted out a plank lining was put in, leaving enough width to give 6 inches of space on each side of the block. The space between the rough and ragged sides of the pit and the planking was then rammed full of strong concrete, the bottom of the pit being leveled up with the same material. After being left a sufficient length of time to allow the concrete to set, the plank lining was removed, which left a pit with smooth side walls 42 inches in width, or enough width to allow a space of 6 inches on each side of the 30-inch block. Two inches of clean dry sand were then put in the bottom of the pit and a framework of timber placed over the pit to hold the upper end of the block as each plank was put in place. After seeing that the end of a plank is square it is slid into the pit on end, one man being in the pit to place the lower end in position and one above the pit to keep the upper end in its correct place. As each plank is placed it is tapped down to settle the lower end firmly in the sand, and is then spiked to the plank against which it is placed, care being taken not to drive spikes where bolt holes will afterwards have to be bored. All joints of the planks should be broken, which is accomplished easily by using planks of several different widths. For instance, in building this 30-inch block, we used planks of the following widths: 12 inches, 10 inches, 9 inches, 8 inches and 6 inches. With these widths the requisite 30 inches of width was obtained by using two 12-inch and one 6-inch planks, three 10-inch planks, one 12-inch and two 9-inch planks, or three 8-inch and one 6-inch planks. Also by using these varying widths any size logs can be cut up economically. After the block is all spiked together and seen to be in its correct place, the 6-inch space around the block is carefully tamped full with clean sand.

The "mud" sills are now laid on each side of the block and lengthwise with it. In this case we use 12-inch by 12-inch pine laid on a foundation of cement. Four of these sills were used, one near each side of the block and one near each end of the 16-foot "streak" sill, which is placed upon them as shown in the drawing. These streak sills are placed closely against the ends of the battery block and bolted firmly to the mud sills, which together form a framework of timber about the block. The streak sills, in this instance, were yellow pine, 12-inch by 18-inch cross-section, 16 feet in length, which is about the average size of timbers used for this purpose. These streak sills are "gained" out 2 inches to receive the mud sills, and on top mortises are cut 8-inch by 8-inch by 6-inch in depth to receive two tenons on the end of each post and brace of the frame, as shown by dotted lines.

The main post has a height of 20 feet perpendicular from the top of the streak sill to the top of the post, and a total inclination of 30 inches in its length. The brace in front of the post has a total perpendicular height of 13 feet 7 inches, and a total inclination of 25 inches in its length. The brace and post are keyed together by two wooden keys, one 6-inch by 10-inch, and one 4-inch by 4-inch, as shown in the sketch, and are firmly bolted together with bolts. At the base of the posts and braces a binding timber is placed across the streak sills, and the space between them and the side of the block and between the two posts and braces at each end of every block are filled with short pieces of timber, shown in the sketch in end sections and marked blocks. These binding timbers and the braces and posts are then all bolted together by long bolts passing horizontally through all, after which the binding timbers are also bolted to the streak sills. This gives a very fine frame-

work about the battery block, as well as holding the post and brace firmly in place. The end posts and braces are 12-inch by 24-inch in cross-section, while the center post and brace of a group of batteries which receive the end of two cam shafts are made 20-inch by 24-inch in cross-section. If logs of large enough size cannot be obtained from which to saw such sized timber, they may be built up of two 12-inch by 12-inch and two 12-inch by 20-inch timbers, for the two different sized posts and braces required, firmly bolted and keyed together. These will give very nearly as good satisfaction as would one solid stick of timber.

A "gain" near the top of the brace receives the lower "guide rail," a timber 14-inch by 16-inch, shown in end section, and a gain near the top of the post receives the

The "A" Frame Battery Post.

upper guide rail, a 14-inch by 14-inch timber. These timbers are so framed together that they stand perpendicular, one above the other, and the inner side of them to be 4 inches from the center line of the stamp to receive the 4-inch guides for the stamp stems. The lower guide rail is bolted through brace and post to the frame, and the upper rail through the post, thus completing a very solid frame. The small circle at the back of the streak sill represents the driving pulley on the battery line shafting, and the large circle above the cam-shaft pulley. The line of the driving side of belt is shown by the arrowheads.

To steady the frame from behind, the timbers supporting the bottom of the ore bin are projected so as to reach the back of the battery posts opposite the top of the brace. This thoroughly takes up the horizontal pull due to the horizontal component of the pull of the belt.

I was superintendent of the Antelope S. M. Co. at Aurora, Nev., in 1864, and there first saw the "A" battery frame in the Fogus mill, which was built in 1863 under plans and supervision of a millwright by the name of Cutter, and I was so favorably impressed with its arrangement that I adopted it in building the 16-stamp mill of the Black Bear Co. in 1872, employing A. J. Rigby as millwright, who drew the plans by my instructions. In 1873 Mr. Rigby constructed an additional battery of sixteen stamps at the Black Bear mill, and a 32-stamp mill for the Klamath Company near here, both having the same style and giving good satisfaction. In 1876 or 1877 he went to the Black Hills, where he built the Caledonia mill, and according to Mr. Nesmith, who was in charge of one of the properties there, he was employed in the construction of the Father De Smet mill in some capacity.

My experience fully corroborates the indorsement given by Mr. Barrell, as the frame is compact and rigid, the belt strain is endwise of the battery posts, and the cam shaft boxes being also on the end of the timbers there is, therefore, less vibration.

The Fogus mill also was equipped with cams having a single horn, which, however, do not seem to have met with favor since.

Aurora at the time mentioned boasted of over 150 stamps—the Del Monte with 30, the Antelope and Wide West, each with 20, were all fine brick structures. The Del Monte in the seventies was moved to Bodie and became the Standard mill that produced many millions.

In the Antelope and Del Monte mills two 1500-pound stamps each were used, dropping 3 feet upon a die surrounded by grating, which served the purpose of the more modern rock breaker. It was at these mills that I first saw the gib tappet in use. T. Machell, the superintendent preceding me, claimed to have first introduced it. He was a miner and machinist of considerable experience in Tuolumne county, Cal., before coming to Aurora.

In 1860 I purchased of the Donahue Foundry, of which J. Brody was foreman, a 4-stamp mill, which, in company with others, I erected near here. The stems had key seats cut crosswise for the purpose of holding the tappet, but although better than set screws, which were first given a trial, the drop of the stamps could not be equalized readily. In 1862 I purchased of the same establishment a 12-stamp mill

for the Black Bear Co., of which I was then a member, and the stems had a flattened space for a distance of about a foot for a tappet key way. I mention these facts to show that up to July, 1862, the principal mining machinery establishment had not introduced the gib tappet, as well as to illustrate the progress of improvement in crushing appliances. Black Bear, Cal., April 14. JOHN DAGGETT.

### Gold Dredging in Oroville District, Cal.\*

NUMBER II.

Written by L. J. HOHL.

The Bucyrus boats, in some instances, have, right under the shaking screen, or under the tables, placed a distributing device which works very well toward getting the flow over the different tables regulated. The tables themselves are arranged in small units from 2 feet 6 inches to 3 feet wide, running at right angles to the drum or shaking screen, and are provided with arrangements to shut off the flow from any unit for the purpose of cleaning it up.

From these tables the material is carried off by longitudinal sluices, also provided with riffles, which deliver the material well back of the stern of the boat.

The Risdon boats use cocoa matting with expanded metal for a riffle, which needs a good deal of attention, but is claimed to be very effective.

The Pennsylvania boat, built by the Golden State & Miners' Iron Works of San Francisco, Cal., uses a nest of riffles in layers under the upper portion of the screen, a unique device, to which the name of beehive riffle has been given locally.

This boat also has a double screen, which separates the largest gravel from the finest before the ultimate screening is being accomplished.

The tailings are taken care of by the tailings stacker, or conveyor, at the stern of the boat. This conveyor consists of a long, inclined ladder, built out of structural shapes in various designs, supporting the chain of buckets or the endless belt for the carrying off of the tailings, together with the necessary appliances for driving and guiding the chain or the belt.

The Risdon stacker consists of a chain of light buckets; the other boats use endless rubber belts, both the chain and the belt being driven from the outer or upper end of the stacker in the latest type of boats.

The former appliance—that is, the chain of buckets—is said to cost but little for repairs, while the latter no doubt gives less occasion for shut-downs, but, as a belt will only last from six to nine months, costs a great deal for repairs. An experiment which has been tried on two of the dredgers in the district with fair success will probably ultimately solve the problem of repairs. It consists in running an independent belt of much smaller width, say 16 inches, in the center of the main troughing belt, thus exposing the smaller belt to the greatest wear and saving the main belt, which is from 28 to 32 inches in width.

A majority of the boats include in their equipment a sand pump for the purpose of pumping the surplus sand through a pipe running up along the stacker ladder and delivering it back of the tailings pile, thus keeping it from crowding in on the boat. This pump is a great power consumer, and, naturally, is only used in case of absolute necessity. In fairly deep ground it need never be used, except in the beginning, and even then it has been proved to be superfluous by recent developments; so that the time is not far off when the sand pump will be entirely discarded, except for such ground as contains very abnormal quantities of sand.

The power for the boats in the Oroville district is furnished by the Valley Counties Power Co. in the shape of three-phase A. C. at a voltage of 4000 to 5000, which is transformed either on shore or on the boat to 400 or 500 volts and then delivered to the different motors.

The cost of the power is 1½ cent per kilowatt hour.

The motor equipment of a typical 3-cubic-foot Risdon boat consists of the following: One 50 H. P. variable speed motor for bucket line, screen and stacker; 30 H. P. motor for water pump; 10 H. P. motor for winches.

The motor equipment of a 5-cubic-foot Risdon boat is: One 50 H. P. variable speed for main drive; 40 H. P. for water pump; 20 H. P. for drum and stacker; 10 H. P. variable speed for winches; 10 H. P. for ladder winch.

The motor equipment of a 3-cubic-foot Bucyrus boat is: One 50 H. P. variable speed for main drive; 20 H. P. variable speed for winches; 30 H. P. for water pump; 20 H. P. for stacker and screens; 30 H. P. for sand pump; 3 H. P. for auxiliary water supply.

The motor equipment for a 3-cubic-foot Bucyrus boat is: One 75 H. P. variable speed for main drive; 20 H. P. variable speed for winches; 20 H. P. for stacker; 15 H. P. for shaking screen; 50 H. P. for water pump; 40 H. P. for sand pump; 5 H. P. for auxiliary water supply.

The equipment of motors on the largest type Bucyrus boat built on the Yuba river is as follows: One

\* Abstract Trans. Cal. Min. Assn.

100 H. P. variable speed for main drive; 50 H. P. for water pump; 50 H. P. for sand pump; 20 H. P. for stacker; 20 H. P. for shaker; 30 H. P. variable speed for winches; 7½ H. P. for auxiliary water supply.

The motor equipment on the new Marion boat at Oroville, built for the Boston & California Dredging Co. in conformity with their ideas and practices, developed by experience, is as follows: One 100 H. P. for bucket line; 30 H. P. variable speed for ladder hoist; 50 H. P. variable speed for main pump; 20 H. P. for screen and stacker; 20 H. P. variable speed for winches; 10 H. P. for auxiliary pump.

From data obtained at different times and from different sources the author has been enabled to give the following averages of the consumption of power on different boats for the various purposes:

Three-cubic-foot Bucyrus boat—Main drive, 26 H. P. to 45 H. P.; stacker and screener, 12 H. P. to 16 H. P.; water pump, 45 H. P. to 50 H. P.; winches (maximum), 28 H. P.; sand pump, 32 H. P. to 50 H. P.

Five-cubic-foot Bucyrus boat—Main drive, 42 H. P. to 70 H. P.; stacker and screen, 10 H. P. to 20 H. P.; water pump, 50 H. P. to 75 H. P.; winches (maximum), 27 H. P.; sand pump, not tested.

Five-cubic-foot Risdon boat—Main drive, 60 H. P.; water pump, 52 H. P.; screen and stacker, 18.5 H. P.; other motors not tested.

Yuba dredge—Main drive, 108 H. P.; water pump, 68 H. P.; sand pump, 63 H. P.; shaking screens, 11 H. P.; auxiliary water supply, 13 H. P.

The average running time of the boats varies a great deal in different months and under different circumstances. A new boat will be able to make better running time, as no serious breaks are likely to occur if it has been made strong enough in the first place. A breakdown of any magnitude, such as upper tumbler shaft, lower tumbler shaft or bucket line, will cut down the average running time. Where the boats are influenced by the stage of the water in the river, high water may seriously hamper them at certain seasons, and last winter was an exceptionally severe one in this respect, high water occurring as early as November, 1903, and being with us all through February and March of 1904. To show an extreme case, I have taken a selected year in the run of a boat exposed to the high water, so that the year contains all the high water of last season.

Besides high water troubles, the bucket line was in bad shape and broke frequently; the upper tumbler shaft broke twice during the period under consideration, the lower tumbler and its shaft had to be renewed, and also the conveyor belt, and, to cap the climax, the power was abnormally unsteady and unreliable during most of that year. The running time of the boat, figuring on the basis of 365 days in the year and twenty-four hours to the day, was sixteen hours out of twenty-four, or 66⅔%. It may seem odd to call particular attention to the fact that in this calculation the year is taken as having 365 days and each day to have twenty-four hours; but when you look over the records of some of the boats you will find that some of the stoppages are not counted on, such as high water, holidays, etc., the owner or manager arguing that the dredger should not be charged with any delays not originating on the dredger or its appurtenances. The simple fact that the dredger is not earning anything when it is stopped, whether such stoppage originates within or without the dredger, and which fact finds expression on the balance sheet of the company at the end of the year, is sufficient to show the fallacy of the assumption. Returning to the case under consideration, I append a tabulated statement, showing the causes for the different stoppages in per cents, as an indication of the weak points of that particular dredger during the selected period:

#### CAUSES OF STOPPAGES IN PER CENT.

(TO BE CONTINUED.)

WHEN melting babbitt metal care must be taken not to overheat it, or the more easily melted constituents partly evaporate, leaving the alloy in bad condition. Melt a small part first and gradually add to it until all is melted. Then skim off the top and the metal is ready to pour. Before pouring the metal wrap a sheet of smooth writing paper around the shaft or other journal to be babbitted, and secure it by winding a string about it, spirally, in turns half an inch apart. Then place in the bearing and pour the metal. The paper keeps the cold iron from too quickly chilling the babbitt and gives it a smooth surface, while the grooves made by the string make good oil conduits. It will be found, if this is properly done, the journal will fit the bearing nicely and will require no scraping.

## Formation of Ore Bodies on Intersections.\*

NUMBER II.—CONCLUDED.

Written by MARK B. KERR.

When the writer was appointed general manager of the Grass Valley Exploration Company in Grass Valley, he was granted by the directors a free hand in development. Systematic exploration was immediately begun, as the reserves of milling ore then in sight were limited. A winze had been sunk some few feet in the hanging-wall of the drift. At this point (No. 1, Fig. 1) a cross slip on a joint plane intersecting the main vein at almost right angles was noted; by driving along about 200 feet on this joint or fracture plane, at another point of intersec-

Fig. 1.—Ore Deposit at Intersection of Seams.

Fig. 2.

Jumper mine in Tuolumne county (the writer was in charge of this property for nearly three years). The Jumper fissure is composed of closely banded streaks of gray slate and schist, which contact in depth with streaks of grano-diorite and diabase of the same appearance as the wall rock of the Grass Valley veins. The grano-diorite and diabase is in the nature of a dike, and is of greatest extent on the north end of the property at the Golden Rule and is more in evidence in the upper than the lower levels. The fissure is noticeable for the limited quantity of the black Mariposa slate so plentiful in the Mother Lode fissures of Amador and Calaveras counties.

After careful study it was discovered that this closely banded strata of slate, grano-diorite, diabase and schist contained small transverse veinlets, the quartz being replaced by calcite. This is particularly evident on the 1000 north level (see Fig. 4), although the diabase is absent.

Near the surface and for several hundred feet in depth, these crossings were gold bearing, the latter being probably freed by oxidation, but were supposed to be a part of the vein, and enrich it considerably, the general strike of the vein being nearly true north and south and dip 65° to 75° E. Having settled the fact that the calcite seams were responsible for the coarse gold deposition characteristic of the mine, a systematic exploration was started to discover these enrichments in depth. At first, only

Fig. 3.—Crossings in Jumper Mine, Stent, Cal.

Fig. 4.—Occurrence in Jumper Mine, Stent, Cal.

tion (No. 2, Fig. 1) a new pay shoot was encountered. Afterwards, a raise was made from the bottom of the winze to discovery point No. 2, and a great deal of excellent milling ore taken out of this intersecting vein. Anyone interested in this exploration can find further details in the records of the Circuit Court of Northern District of California (Penn. Con. Min. Co. vs. Grass Valley Exploration Co.).

The legal rights of the possession of this ore body is one matter, but the fact remains that, by vigorous development in the legitimate pursuit of mining and as the practical miner would say, on our own foot-wall, we discovered an additional pay shoot of ore by following a joint plane in the granite.

In this stope transverse veins dipping east were noted, a cross-section of which will show the upward trend of ore deposition along transverse fracture veins. The adjacent country rock was seemingly mineralized only two or three feet beyond the wall of the fissures.

A somewhat parallel condition can be cited at the

one system of these calcite impregnations was found striking N. 40° to 50° E and dipping 30° to 50° N., but afterwards a second series striking the same but dipping to the south at a somewhat flatter angle were discovered; where intersections occurred either on the points or apices of these transverse veinlets or in corresponding troughs or depression, this enrichment with free gold was observed. Raises made on these calcite seams on angles from 30° to 50° proved that they followed the lines of fracture of the banded structure and passed through not alone the slate, but into the diabase and schist as well, the largest width of the crossing, 8 to 10 inches, being in the slate, while in the diorite or diabase the crossing was sometimes as small as a pencil line.

Taking the general form of the old stope ground (which was excavated mostly on the rake of the north dip crossings), and extending theoretical projection lines to the 1000-foot level, the supposed mathematical line of enrichment was found to strike farther north. This north 1000-foot level had been run in previous years over 600 feet without encountering pay rock. The level was extended

\* Abstract Trans. Cal. Min. Assn.

only 10 feet through the closely banded strata of the vein when crossings of the south dip series were encountered carrying free gold, a fact proving the theory of ascending gold-bearing solutions, depositing free gold within the calcite crossings, these crossings being parallel to the lines of fracture and joint planes of the country rock. One point of geological interest was noted. In the slates, diabase and schists, quartz was replaced by calcite, while in the grano-diorite the crossings were composed of quartz.

In looking at Fig. 3, a most homely illustration occurs to me. If you take an ordinary set of Japanese boxes, one within the other, and gradually unnest them, the last inside box will preserve the same form as the first and largest one. So with the form of the Jumper ore body. As seen on the diagram, the main pay shoot is in the form of a large parallelogram outlined along the massive structure; reduce this to an intersection of two series of gold-bearing crossings and the form becomes a rhombohedron. Again, take a good-sized crystal from the same inter-

## The Strength and Life of Mine Timbers.\*

NUMBER II.

Written by W. H. STORMS.

Believing that valuable information could be obtained by addressing some of the other members of this Association, I sent out the following inquiries. Please state:

1. The kind of timber employed; that is, whether yellow or sugar pine, spruce, fir, Oregon pine, etc.
2. Its condition at the time of going into the mine, whether well seasoned or not.
3. Its position in mine with reference to excavations; that is whether in stope, drift or shaft, and its relation to air currents, as there seems to be considerable difference with reference to the enduring qualities of a stick of timber, dependent on its location, whether in still air or in a current of considerable velocity; and also whether the air current is compar-

Grass Valley, Cal., who thus briefly but carefully answers the questions:

- No. 1. Yellow pine and spruce.
- No. 2. Used after being cut about eight months.
- No. 3. We use yellow pine in stopes, and in places where not much life of timber is required, and spruce timbers is used in drifts and drain tunnels.
- No. 4. Stopes are usually damp and fungus forms on timbers after six months.

No. 5. A, spruce, wet ground where water is trickling over constantly will last indefinitely, but in damp ground about three to five years; b, yellow pine about two years.

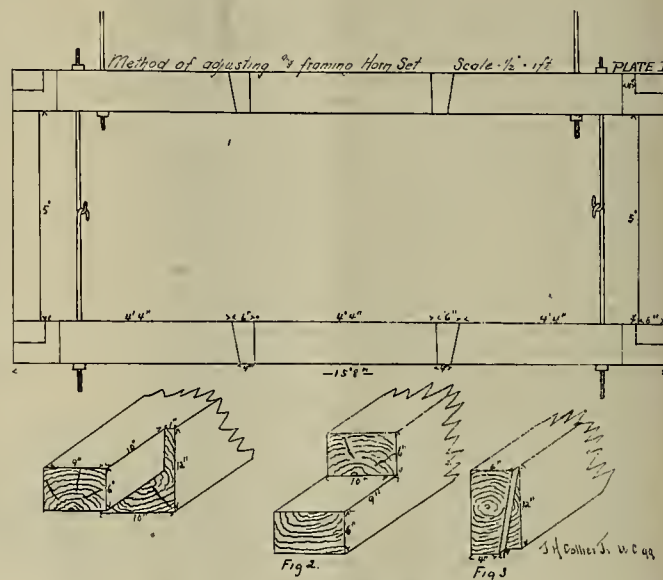

No. 6. Spruce.

The Empire mines in granite, the veins for most part have a low dip, and the type of vein formation is entirely unlike that found on the Mother Lode.

John Ross, Jr., for many years superintendent of large mining interests in Amador county, Cal., and elsewhere, kindly contributes the following:

A Stope Timbered in Square Sets.

Side View of Shaft Set.

Mine Timbers Piled Up for Winter's Use.

Hauling Mine Timbers from the Forest.

section and fracture it with a hammer. In its smallest fragment the same form and fracture will be observed. For further details of this fracture and joint plane theory, see testimony of Louis Janin in Penn. Co. vs. Grass Valley Exploration Co.

Now, apply these practical remarks to ore bodies and we can outline a definite line of exploration. First—Solutions of ascending waters will by metasomatic processes be deposited more frequently on the fracture seams of the vein. Second—After the definite strike and dip is obtained of the fracture seams, the enrichments are more liable to occur on these lines mathematically projected at other points.

An earthy charcoal sometimes found in eruptive rocks is due in some cases to pieces of coal detached from beds through which the eruptive rock has forced its way. In other instances it is due to wood becoming inclosed in the rock. The latter has been known to occur with volcanic rocks, such as andesite, though the former may occur with non-effusive rocks, like felsite, diorite, etc.

atively pure, fresh air, or whether heavily laden with carbon dioxide and other foul gases peculiar to mines.

4. The condition of moisture of the air; is the stope damp? Does fungus form rapidly on the timbers, or is it comparatively dry and free from these formations?

5. How long, in your experience, should a stick of timber, say 20 to 30 inches, endure under average conditions, in a well ventilated drift, in a damp mine (a, spruce; b, yellow pine; c, sugar pine; d, fir; e, redwood)?

6. What, in your opinion, is the best timber for all-around underground use in mines? Have you ever noticed any material difference in the various kinds of timber, of equally good condition; that is, well seasoned sticks?

To this letter I received a number of replies, the answers in most instances agreeing, not only with my own experience, but with each other.

The first response was received from George W. Starr, managing director of the Empire mines at

\*Abstract Trans. Cal. Min. Assn.

“Regarding the strength and durability of timber in mines:

1. Oak, spruce, yellow pine, Douglas spruce (commonly called Oregon pine), bull pine, sugar pine, native fir.

NOTE.—Oak is rarely used, on account of its scarcity, but I know a shaft that was sunk in '59 and '60 and kept open for seven years—part of the shaft was timbered with oak. The mine then laid idle for twenty years, the shaft being full of water. It was reopened in '87, and has been kept open until the present time. The oak timbers stood until 1901, and at that time the wall plates and sills were in perfect condition, and would not have been changed but for the fact that the pressure on the end timbers—or legs—had been great enough to crush the ends a little, making them too short to be used again. This shaft is an incline, and a little water was continually trickling over the timbers—enough to keep them thoroughly wet all the time. Under the same conditions a few sets of timber made of hull pine also stood in the same shaft for forty years, while spruce, yellow pine, Oregon pine and fir had to be changed several times, the timber lasting in the order given, and its life in the shaft being from two to eight years, where the

timbers were always wet. But in other parts of the shaft where the timbers are wet and dry alternately the life of the timber ranges from one to three years. This shaft, however, is an exceptionally hard one on timbers, being sunk on the vein fissure and in the "gouge," and the pressure on the timbers is not equal. In justice to the other members of the timber family, it is but fair to say that the oak and bull pine were used in the narrowest part of the vein, where the pressure was not so great as where the gouge was wider.

2. The condition of the timbers going into the mine varies from green, "fresh from the axe," to thoroughly seasoned—that is, timber that has been cut for two years. Where the timbers are sound when going into the mine and they are placed where water trickles over them, there is practically no difference in the life of a seasoned timber or a green one, but in a dry or a damp drift the seasoned timber is preferable, partly on account of less cost in handling and putting in place, and furthermore, it is not so quickly attacked by the fungus growth or "dry rot."

NOTE.—I have seen great timbers placed in a damp drift attacked with fungus growth within about two weeks of the time it was put in place, but this is not common.

3. The position of the timbers in the mine relative to air currents and the purity of the air has more to do with its life, in my opinion, than any other thing.

NOTE.—In making a connection between two shafts, 1000 feet apart, work was commenced from each shaft, the air being forced down each shaft to the face of each drift, giving plenty of good air for the workmen. The work was not rushed, taking about a year's time. During this time the timbers stood well, showing no sign of "dry rot" or fungus growth. When the connection was made the air came through the drift with considerable velocity, making one shaft a "downcast" and the other an "upcast." Near the downcast shaft the drift and stope was 30 feet wide, and heavily timbered. These timbers stood for six years with practically no repairs. Between this place and the upcast shaft the drift was opened out to a width of from 20 to 30 feet in a number of places in stoping, the drift proper being kept as straight as possible, and through which the most of the air came. It was quickly noted that the farther we got from the downcast shaft the worse the conditions of the timbers became—they being attacked with fungus growth and "dry rot." It was also noted that where the drift had been widened for stoping purposes the timbers that were out of the direct current of air were not so quickly attacked, and experience afterward showed that they would last twice as long. The life of timbers that were in direct line with the air current was from one to two years, and when not fairly in the current from two to four years. It was also noted that the timbers in the upcast shaft above the point of connection soon became seriously affected, necessitating considerable repair work. As the property became more developed this experience was duplicated in three different levels.

Another instance proving the above may be mentioned: We are now opening out a caved portion of one of these connecting levels where the drift proper had been retimbered three times before it caved. In our work now we find the drift timbers to be little more than punk, while the stope timbers that came down with caving of the drift are as sound as when placed in position. These stope timbers did not come into direct contact with the air current. Many of these stope timbers had been in place at least three or four years longer than those in the drift.

4. Warm, moist air in a mine that has but one shaft is far more destructive on timber than dry and comparatively cool air. In the latter instance the timber will last at least twice as long.

5. A, spruce, about six years.
- B, yellow pine, about five years.
- C, sugar pine, about four years.
- D, fir, about two years.
- E, redwood, never used any.
6. For all round work, spruce.

NOTE.—At one time a comparative test was made at this property in a raise where the ground was very heavy. Oregon pine, 12x12 inch, was used on one side, and 14 inch round native yellow pine on the other. In one year the round yellow pine stick was badly bent and twisted, and the legs were forced into the wall plate 3 inches, but there was still strength left in the timber to hold the ground, while the 12x12 sawed timber Oregon pine was shattered into slivers, and could bear no further pressure. None of the timbers used in this test showed any rot or fungous growth.

To G. McM. Ross, a mine superintendent and manager, whose experience in California, Arizona, Nevada and elsewhere I consider of great interest, I am indebted for the following:

1. I have used many kinds of timber in various conditions, from green, wet wood, fresh from the sawmill pond, to old telegraph poles, railroad ties, sagebrush, and the juniper of Nevada, also the fiber of the tall cactus of Arizona.

The above answers your second question.

3. Any timber will last longer in a stope or drift that is well ventilated with fresh, pure air than where there is a limited supply of fresh air, or none at all.

4. Timber of any kind will last longer underground when wet, or when there is sufficient moisture in the ground or air to keep it damp. Fungus will not form on timbers where there is a good circulation of pure air, but will and does form rapidly where there is little or no air. In parenthesis I would like to suggest to you, what I have to others, that in my judgment there is a pretty intimate relation between the

fungoid growth on timbers and the phases of miners' so-called consumption. We have never succeeded in having the question looked into in the proper light, or the necessary investigation made.

In answer to your fifth question will say that it is impossible to figure on an average condition. We have seen large timbers crushed into slivers in a few days underground, and again have seen timbers of the same size perfectly sound after being underground for forty years. Spruce, yellow pine, fir or cedar, in a well-ventilated damp mine, where there is no excessive pressure, should last for fifty years. Sugar pine, which is the very best timber that we have, is now too valuable for mining purposes, and redwood is not fit for mining work in heavy ground.

6. Any available sound pine, thoroughly seasoned, is the best timber for all around mining work. Timber that will best resist an end-thrust is the most serviceable for mining work.

In the matter of preservation of timber for underground work no preservative containing a fluid that can be rendered volatile, or emit a gas, can be safely used. We have never found a timber, with the exception of sugar pine (and, as previously stated, this is now too valuable), that would resist the action of the soil or surface dirt. It commences to rot practically as soon as it touches the ground, so that in the construction of mining buildings, shaft houses, ore bins, etc., no timber that is to take weight should be placed upon the ground, but should set upon a foundation of brick, stone or concrete.

Ten years is a long life to give to the mudsills of any building that are not kept thoroughly wet. Shaft timbers, regardless of the character or kind of wood, should be kept wet, and selected so as to offer the greatest resistance to end-thrusts.

In repairing shafts we have often had timbers taken out with perfectly sound centers, the ends of the sticks being splintered by pressure and then rotted by being kept wet for only part of the time. In dry, hot mines, such as the Comstock, a great deal of timber loses all of its strength by a slow process of distillation, the residues being of brownish color, and in many cases no heavier than punk.

While the use of timber is absolutely necessary in nearly all mining work, there has been beyond question a wanton waste of magnificent timber. Effort should be made to develop systems in which a minimum quantity of timber is required. Stopes of large size should be filled, and in every possible way the timber taken underground should be reduced to a minimum.

(TO BE CONTINUED.)

## THE PROSPECTOR.

Those sending rocks, ores or minerals for determination are requested to send name and address plainly written, so that in the event of a personal letter becoming necessary the sender of such samples may be reached. Some packages are sent with no other name than "Subscriber," and as the MINING AND SCIENTIFIC PRESS has thousands of subscribers who are scattered in every corner of the world it is impossible to know who the correspondent is. It is also desired that rocks, minerals and ores be sent, whenever practicable, in mass, and not pulverized. It is not the intention of "The Prospector" to make assays or analytical tests, but to simply aid the prospector by telling him as clearly as possible the character of his minerals, ores and rocks, that he may the more intelligently pursue his investigations in the field.

The rocks and minerals from Quartzsite, Ariz., are: No. 1, fine-grained mica schist. No. 2, talc schist, with crystals of limonite pseudomorph after pyrite. No. 3, talc schist, same as No. 2. No. 4, quartzite. No. 5, quartzite. Nos. 6 and 7, sandstone. No. 8, a dense quartzite, with a little secondary mica in the jointing planes. No. 9, dense quartzite, from an outcrop. No. 10, quartzite, with limonite and a little copper carbonate—the small pieces are mostly iron oxide, copper carbonate and silica. No. 11, chalcocite (copper glance). No. 12, copper glance, with much impurity, principally iron oxide. No. 13, grains of quartz, with many groups of the talcose mineral called pyrophyllite. No. 14, quartzite, with a scabiose structure, induced by pressure. No. 15, also quartzite. The rocks are all of sedimentary origin, but all metamorphosed, with the exception of Nos. 6 and 7, which are sandstone and metamorphosed but little if any. The rock containing pyrophyllite is probably the result of contact metamorphism. The best ore is No. 11, and should be shipped at a good profit if sufficient of the ore is available.

Tests for the presence of gold in rock, when none can be obtained by panning, are too delicate for the prospector in the field. Tests for silver may be more easily made, however, by dissolving some of the mineral in nitric acid, diluting the solution with water and adding a few drops of hydrochloric acid, or of a solution of common salt. If silver be present in any appreciable amount it will be precipitated as white chloride of silver. Unfortunately this test will not

do for silver chloride, as it is not soluble in nitric acid, and this is the ore the prospector is most likely to find in his search, as it most commonly occurs in the surface outcrop of silver veins. A solution of hyposulphite of soda dissolves silver chloride, and is precipitated by sodium or calcium sulphide, made by boiling lime or soda with sulphur. A few drops of either of these will cause any silver to be precipitated as the black sulphide of silver. Copper, lead and manganese are also precipitated by these sulphides, each having a distinctive color, with which the prospector must familiarize himself.

The samples from Callahans, Cal., are: No. 1 is chalcopryite (copper sulphide) in quartz, brown iron oxide and a little blue carbonate of copper present. No. 2 is mostly dolomite (lime magnesia carbonate), with a little ankerite appearing in light brown patches. This rock contains iron sulphide and probably also gold.

The mineral samples from Columbia, Goldfield mining district, Nevada, are: No. 1, from Eugene No. 4, rhyolite tuff. No. 2, from gulch north of Eugene group, pumice (a volcanic product). No. 3, also pumice. In time, with low transportation charges, these materials may become of economic value, but situated as they are at present are commercially worthless.

The minerals from Denio, Or., are: No. 1, an ore consisting of red oxide of copper (cuprite), green carbonate of copper (malachite), and blue carbonate of copper (azurite). The gangue mineral is fine, granular quartz. There is also present in this little ore specimen jasper, iron oxide, manganese oxide, a little copper glance (chalcocite), magnetite, pyrite, chalcopryite and kaolinized feldspar. All of the copper minerals present are due to the oxidation of chalcopryite, except the chalcopryite itself. No. 2 is jasperoid (silica), with a few specks of cinnabar (mercury sulphide). No. 3 is a metamorphic rock, probably occurring at or near a granite contact. The principal minerals visible are quartz, feldspar, biotite and muscovite, garnets and fluor spar.

The mineral marked 44 Rio Dolores M. Co., Rico, Colo., is principally lead sulphide (galena), the bright, crystallized, lead-colored mineral, and zinc sulphide (sphalerite), the dull-gray, fine-grained mineral. There is a small amount of iron sulphide also present. The white gangue mineral is carbonate of lime. This ore treated by magnetic separator will yield a lead and a zinc product.

The rocks from Lundy, Cal., appear to be volcanic mud, indurated, and carrying a large amount of finely disseminated magnetite. The smooth, polished surfaces are due to movement of fragments of the rocks upon themselves. There is also considerable pyrite along the edges of the rock.

The minerals and rocks from Shoup, Idaho, are: No. 1, pyrite, galena and zinc blende in a quartz gangue. No. 2, a dolomitic mineral in which there is a little galena. No. 3, quartz diorite in which there is a little disseminated chalcopryite. No. 4 is apparently diabase, but is much altered—what was evidently originally olivine is now altered to serpentine.

The mineral samples from Seattle, Wash., and marked "cyclopean," are determined as follows: No. 1, chalcopryite (copper-iron sulphide), with a little quartz and other vein material partly feldspathic. No. 2 same as No. 1, with less gangue mineral. No. 3, chalcopryite with disseminated crystals of tourmaline. Nos. 4 and 5 are stibnite (antimony sulphide).

The rock samples from Fort Jones, Cal., are of interest. The black rock is evidently a metamorphosed clay rock, now silicified and impregnated with pyrite. It resembles some black aphanitic diorite, but it shows no sign of the characteristic crystalline structure of diorite, and there are no magnetite grains, so abundant generally in diorite. The gray rock is felsite, an intrusive dike rock, sometimes forming large mountain masses. It shows abundant round inclusions, which indicate that the rock at one time was more glassy than at present, and these spherules are the remnants of its former perlitic structure. It has also been silicified somewhat.

For good drainage a tunnel should have a grade of at least 2.5 inches in 100 feet, and 4 or 5 inches is better. If a very low grade be given the tunnel should be provided with a drain box, either beneath the track or at one side, which must be kept clear of debris. Sometimes only one part of a tunnel, drift or crosscut makes all the water, the balance being dry. In the event that this wet portion is a long way from the mouth of the tunnel or the shaft it is a good idea to construct a small reservoir to collect the water which may then be carried out in a pipe, keeping the remainder of the tunnel dry and possibly permitting some advantageous use of the water, such as driving a fan or air blast, or running a small water wheel for some purpose. The efficiency of this scheme depends upon the volume of water in the tunnel and the head at which it may be applied outside the tunnel.

# Mining and Metallurgical Patents.

PATENTS ISSUED APRIL 11, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

PROCESS OF TREATING ORE.—No. 786,570; E. Kelly, Dover, and A. Munson, Hibernia, N. J.

Process of treating ore bearing magnetic substance which consists in first separating ore of given size from ore, or fines, of less size, drying ore of less size, subjecting ore of larger size to action of magnetic separator having given strength whereby to separate out, as heads, all ore having given percentage of magnetite from that, as tails, having less, and then reducing tails and subjecting them, reduced, and fines, to further magnetic separation.

PUMPING JACK FOR OIL WELLS.—No. 786,854; R. G. Strother, Findlay, Ohio.

In device of class described, base having plurality of spaced blocks disposed in two sets in alignment with each other, uprights mounted between and extending upwardly from outer blocks, inclined braces for uprights, abutments secured upon latter, crosshead engaging uprights and moving vertically upon latter, spaced blocks arranged in pairs upon under side of crosshead, operating levers pivotally connected with blocks, auxiliary levers connected with operating levers intermediate ends of latter by means of transverse rods, pivotal connecting means between lower ends of auxiliary levers and base blocks, operating bars, and transverse rod connecting latter with free ends of operating levers.

ORE CONCENTRATOR.—No. 786,799, P. H. Craven, Rossland, Canada.

In ore concentrator combination with frame thereof, of endless belt suitably mounted for rotation to carry its upper and lower sides in opposite direction, belt being transversely inclined, troughs for discharging material upon upper surfaces of upper and

lower sides of endless belt, traps secured in position above surfaces of upper and lower sides of endless belts in form of inverted troughs, inner edges of traps being slightly raised above surfaces, and outer edges in contact therewith, longitudinal troughs along lower edges of two tables formed by endless belt, funnel shaped hoppers at lower ends of traps, and means for discharging suitable sprays transversely through traps.

ROCK CRUSHER.—No. 787,322; E. C. Bacon, New York, N. Y.

Auxiliary cheek piece having shoulder, in combination with crusher frame recessed to receive cheek piece and support it by shoulder, and with fixed jaw, movable jaw and cheek plates, latter supported and held in place by cheek pieces and fixed jaw, and means for adjusting cheek piece directly laterally toward and from adjacent cheek plate.

STAMP STEM GUIDE.—No. 786,969; F. W. Hooper, Grass Valley, Cal.

Stamp stem guide comprising casting having means of attachment with battery frame and provided with socket substantially rectangular in cross-section, back and front walls of socket being straight and side walls converging downwardly, socket having passage through front wall for lateral admission or removal of stamp stem, and sectional guide block or box fitting socket, sections of guide block formed with opposed abutting edges oppositely inclined relative to each other and to axis of bore.

ROCK DRILL BIT.—No. 786,952; S. B. Clark, Denver, Colo.

Expanding bit for drills comprising hollow shaft having lateral openings formed therein, laterally moving elongated cutters mounted in openings and extending longitudinally of shaft, and rotating wedges interposed between cutters for separating them with parallel movement and supporting them in cutting position.

ORE ROASTING FURNACE.—No. 786,905; A. C. Johnson, Baltimore, Md.

Rocking ore-roasting furnace or drier having series of shelves, upper surfaces of which are convex, axes of which shelves are at angles to one another and lengthwise of furnace, alternate ends of shelves being free, and means for rocking furnace.

other and lengthwise of furnace, alternate ends of shelves being free, and means for rocking furnace.

MEANS FOR PROTECTING BLAST FURNACE HEARTHS.—No. 787,282; C. E. Dinkey and H. A. Brassert, North Braddock, Pa.

Blast furnace having hearth wall provided with circular rows of separated holes extending horizontally and inwardly from outer vertically extending face below level of cinder notch, and water-cooled plates arranged in series in holes, outer vertically extending face of masonry wall being exposed and accessible between sides of plates, and separated horizontal retaining bands between rows, hearth wall being free from any inclosing jacket.

MINER'S DUMPING CAGE.—No. 787,189; J. Kerst, Springfield, Ill.

In apparatus of class described, combination of cage, tilting platform mounted on cage, oscillative shafts on platform, lever connected with one of shafts, stop with which lever engages, keepers on shafts adapted to fit around wheels of car, arms secured to shafts, and lever mounted on platform and connected with arms.

MINERAL VANNER.—No. 787,190; H. C. Krause, Point Mills, Mich.

Vanner, consisting of bed, inclined pan, two pairs of arms pivoted to bed and to pan, means for adjusting one pair of arms to give more or less inclination to pan, means for vibrating pan, water supply at upper end of pan, and horizontal sifter of less length than pan and supported by and above pan at about midway between ends thereof, sifter having apertured distributing plate arranged therein above sieve and terminating short of ends thereof and provided with laterally extending chute at end adjacent to upper end of pan.

MATERIAL FOR FURNACE LININGS.—No. 785,841; H. G. Turner, London, England.

Process of heating magnesite in electric furnace at temperature of electric arc to point where material crystallizes, cooling resulting product, grinding same, mixing it with suitable binding material which will harden and cause material to set, mixing same with water and pressing it into form of bricks or plates and baking bricks or plates in suitable kiln.

In the Klondike region more than \$200,000 has been expended in ditch construction during 1904, with a view to hydraulicking the coming summer. Although wages for miners are \$5 per day with board, the mine operators have been unable to secure the necessary men to work their mines to their full capacity, probably owing to the fact that the men find it more profitable to work for themselves, or prefer prospecting to working for wages, not an unusual thing in a placer country where the inducements and opportunities are as abundant as in the Yukon basin.

# MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

## ALASKA.

(Special Correspondence).—J. Capperton of Eldorado Creek says that before the wagon road was built from Dawson to Grand Forks the cost of transportation was 25 cents per pound by pack train in summer and 12½ cents per pound in winter on runners. Now with roads charges are ½ cent per pound on wheels in summer and 1 cent per pound on runners in winter. The development of this country has been greatly retarded by blanket locations by those invested with power of attorney, but the bona fide prospectors and miners are making efforts to have this abolished.

Eldorado Creek, April 2.

There are in the Yukon-Tanana country four regions which are producing placer gold—the Forty-Mile region, the Birch Creek region, the Rampart region and the Fairbanks region. The Forty-Mile and Birch Creek districts are among the oldest of the gold-placer producers of Alaska, they are by no means exhausted, and with the introduction of improved methods of mining will continue to yield good returns. It is too soon to predict the future of the newly discovered Fairbanks placers, but they show every evidence of profit if mined by improved methods. The placers are near water transportation on the Tanana, and machinery can be put in at much less cost than at some of the older camps.

Superintendent Hoggatt, of the Jualin mine, near Juneau, is opening the property. The summer will be spent on development work and it is not probable that the mill will be in operation until late in the fall. Superintendent G. Ottorson is opening the Mansfield Co.'s mine, near Juneau.—The Alaska-Juneau property in Silver Bow basin will work a full crew this season.—The Sheep Creek Co. will put on a full crew this month. Superintendent Hammond expects to have all the stamps dropping this summer.—A dredger will be put in below the Mendonhall glacier by a Seattle company.

C. S. Carter of the Rainbow Creek M. Co. is working fifteen men near Seward. He will also run a dredger on Resurrection creek, 4 miles from Seward.—The Ready Bullion mine on Lynx creek is to be worked by N. P. White of Sunrise.

## ARIZONA.

### Cochise County.

(Special Correspondence).—The Calumet & Arizona mine has men at work on the new 200-foot steel stack and 50 feet of it has been completed. The widening of the converter building has been started and it will be 15 feet wider when the work is completed. Two new electric cranes are being put in. The new steel boiler house will have a battery of seven boilers, five 250 H. P. and two 280 H. P. The output at the Calumet & Arizona during March was 2,691,599 pounds of blister copper.

Bisbee, April 17.

W. K. Maull has an option on 125,000 tons of tailings on the San Pedro river, 9 miles from Tombstone. These tailings are from the ores of the old Tombstone mines and average \$4.50 to \$5 per ton in gold and silver. The company expects to build a 200-ton per day plant.—The Manhattan Development Co. has been organized by Lake Superior, Mich., mon, with a capital stock of \$200,000, to bond and lease claims in the Chiricahua mountains, near San Simon. J. H. Rice of Houghton, Mich., is president and W. G. Rice secretary and treasurer.

The report of the Calumet & Arizona M. Co. at Bisbee for 1904 shows that they produced 15,819 tons of refined copper and \$195,926.18 in fine gold and silver. The average number of men employed at the mines was 583 and at the smelter 301. The Oliver shaft is down 1132 feet and the Irish Mag 1250 feet and are connected at the 8th, 9th and 12th levels. At the Mag shaft the diamond drill has found siliceous limestone to a depth of 900 feet below the 12th level.

### Gila County.

The Con. M. & D. Co. is developing copper claims 6 miles southwest of Globe in the foothills of the Pinal mountains. Shaft sinking is being pushed with three shifts. L. G. Stewart is superintendent and T. C. North mine foreman.

### Mohave County.

A crosscut from the bottom of the 175-foot level of the Vanderbilt mine, at Cerbat, has entered a 4-foot vein of good ore. It is being worked by the Cerbat Mountain M. Co.—The shafthouse, shaft and machinery of the Elkhart mine, at Chloride, are being repaired before sinking the main shaft to a depth of 1000 feet.—T. Donahue and J. Polson are working the Katherine mine, at Pyramid. They report that the shaft has been timbered to the surface and drifts have been run off into the ore body, and that as soon as the hoisting plant is put in sinking will be commenced.—Canos & Schemmelpennig have opened rich ore in the Virginia mine, near Chloride.—C. D. Pickering, superintendent of the Yucca Cyanide Co., reports that the shaft of the San Francisco mine, in the Cedar section, which is being sunk to the 500 level, has encountered a large flow of water and a bigger pump will have to be installed to handle it. The ore body has increased and shows permanency. The mill has been running for some time past and turned out considerable bullion.—T. Ewing is putting in two hoisting plants on the Hardy mines, in the Silver Creek country, north of Vivian.

### Pinal County.

The Troy-Manhattan Copper Co. will put in an additional 200-foot stack at Troy. The present smelter is in operation.

## Yavapai County.

(Special Correspondence).—At the Golden Wave mine, near Congress, a tunnel intended to cut the ledge at 1000 feet is being driven. The mill is running occasionally. At the Congress mine, at Congress, more work is to be done in the mine and the stamp mill may again be running before the end of the year.

Congress, April 18.

(Special Correspondence).—At the Nincon mines, near Martinez, a new hoist will be put in with a capacity of 2000 feet. A milling and concentrating plant with fifty tons capacity has been ordered. After the ore is concentrated the tailings will be worked by the cyanide process. The main shaft has been sunk to a depth of 950 feet. In the same district the Saylor G. M. Co., which has taken over the Churchill group, has let a contract for 50 feet of sinking in the bottom of the shaft, giving a total depth of 420 feet.

Martinez, April 17.

## CALIFORNIA.

### Amador County.

At the Rhetta Con. Co.'s Bay State and Rhetta mines, near Plymouth, Superintendent W. W. Worthing reports a good strike in the Rhetta mine. The 10-stamp mill at the Bay State is crushing ore from the new strike in the Rhetta.—It is reported that the California Ore Sampling Co. will build a warehouse at Martell's station, near Sutter Creek, where ore and tailings will be purchased.

The annual report of Superintendent W. R. Thomas of the Central Eureka, at Sutter Creek, shows that for the year ending April 1, 1905, most of the work has been done below the 2100-foot level, as the ore body is wider and of better grade than it is in the upper levels, and it was decided to sink and open up the bottom part of the mine first, as the ore in the upper levels can be held in reserve for the future. On the north side of the shaft, at the 2200-foot and 2300-foot levels, is the principal ore body being mined. This ore averages \$7 per ton. Shaft sinking is now progressing and in a short time it ought to reach the 2400-foot level. Total ore milled during the year was 59,700 tons, yielding \$398,815.81 in free gold and \$2113.43 in free silver; 664 tons sulphurets, \$57,238.11; slimes (lessors), \$315.22—a total of \$458,482.57.

Less bullion charges and reduction of sulphurets.....\$0,543 79

Average value in free gold, per ton..... 6 7153  
Average value in sulphurets, per ton..... 6584  
Average value in slimes, per ton..... 0091  
Average assay of tailings..... 63

Actual value of ore.....\$8 3075

Average net value in free gold, per ton.....\$8 081  
Average net value in sulphurets, per ton..... 8224  
Average net value in slimes, per ton..... 0091

Total net value, after deducting cost of refining bullion and reduction of sulphurets.....\$7 5175

Quicksilver fed inside batteries, ounces..... 30,102  
Average yield in free gold per ounce of quicksilver fed.....\$13 254  
Amalgam cleaned up, ounces..... 61,922  
Average yield per ounce of amalgam..... 80 4313

In presenting the cost sheet, every expense is charged to mining and milling. During the year four new concentrators were put in the mill and duplicate parts for the hoist and the mill have been purchased.

### COST OF MINING AND MILLING.

Cost of mining, per ton.....\$1 42  
Cost of dead work and development, per ton..... 38  
Cost of milling, per ton..... 375

Total cost, per ton.....\$2 175

The secretary's report of work for the past three years shows that the 40-stamp mill has treated 191,648 tons at an average value of \$7.16 per ton, and a total cost of \$2.804 for 1902, \$2.36 for 1903 and \$2.175 for 1904.

### Calaveras County.

Work has been resumed in the Sultana mine at Angels.—The new 10-stamp mill on the mine of D. Koller at Carson has been started.—The Hagerman gravel mine, near San Andreas, has been sold by the Eastland-Gray Co. of Oakland, Cal. A new air compressor is being placed.—The Clary G. M. Co. is working the South Bank on Indian creek, near Sheep Ranch, under the superintendency of W. H. Clary. The main shaft is down 240 feet, and two drifts or levels have been run, one at 125 feet and the other at 240 feet. The company will put in a 10-stamp mill.—J. A. Campbell and C. V. Zim have hounded the Buckhorn mines, west of Murphys, and will begin work of development.

Assistant Superintendent D. McClure of the Gwin

mine, at Gwin Mine, reports that the main shaft will be sunk 200 feet deeper. The winze sunk from the present level on the rich streak recently encountered continued downward holding its width well.—It is reported that men will be put on at the Clark & Mahon mine at Oleta, the owners having completed arrangements to go on with development work.—G. Deitz is working the Croff & McCleary claim at Oleta.—The American Flat Co. has struck a good streak of gravel in their claim at Oleta.—L. Smith and C. Wilson are piping on their claim at Oleta.

### El Dorado County.

Work has been started on the Alpine mine, near Garden Valley.—Work has been resumed on the Gold & Silver mine, near Kelsey, under the supervision of B. L. Peters.—The bedrock cut at the Gravel Hill mine, 4 miles west of Georgetown, has been completed and hydraulicking commenced. This mine is owned by W. Barklage and managed by E. C. Zorres.

### Madera County.

A strike of native copper is reported from the 100-foot level in the Yosemite copper mine, on the Daulton ranch, near Madera, by Superintendent J. M. Hamblton.

### Mariposa County.

The mill at the Mariposa mine, near Mariposa, has been completely destroyed by fire. The loss is about \$30,000; uninsured. The last clean-up was just being finished. The mill was built in 1900 and has run continuously ever since. It had just closed down and would probably have been moved to some other property on the grant at a later date, though it would no doubt have been used for milling ore from nearby mines for a time.—S. L. Brown, superintendent of the Tennessee and California gold mine, near Indian Gulch, is arranging for hauling a hoist, stamp mill and lumber to retimber the shaft.

### Nevada County.

The 10-stamp mill of the Sultana mine, near Grass Valley, is to be increased by 30 stamps. It is also stated that the New Orleans mill, near Grass Valley, is to be enlarged. It is stated that those two mines will build a 2-mile pipe line, as the Empire M. Co. has refused to supply them with water.

### Placer County.

The Cash Rock mine at Forest Hill will commence work this spring.

### San Bernardino County.

Shipments of tungsten ore are reported from a number of claims between Randsburg and St. Elmo.

### San Diego County.

(Special Correspondence).—It has been reported that the Oro Flamme mine, situated on the east side of the Cuyamaca range, on the road between Stonewall mine and Pine Valley, has been bought by the Cuyamaca M. Co., but this has been denied by the company. About seventeen years ago the Oro Flamme Co. built a mill at the mine, and the difficulties of getting the mill in place were so great, owing to the precipitous character of the mountains, that notwithstanding the fact that the mine did not pay, it was considered inexpedient to remove the mill, as it would cost more than the machinery was worth. The nearest prospects to the Oro Flamme are those in Deer Park and Pine Valley. The formation is mica-schist, mica-slate and eruptive rocks of several kinds, and the ores are mostly high grade, though the veins are generally small.

Pine Valley, April 17.

### Siskiyou County.

Work has been started at the American mine, 2 miles east of French Gulch, under the direction of Superintendent Thomas.—A 5-stamp mill will be built on the Dobrowsky mine, near Shasta, by H. O. Cummins, manager of the Middle Creek M. Co.—T-rails are used for rifle bars in the tail races at the Lagrange hydraulic mine on Oregon Gulch mountain, near Weaverville, by Manager P. Bouery.

The smelter at the Aftersought mine of the Great Western Gold Co., at Ingot, is reported to have been closed down, presumably because of some fault in the process of reduction. It is reported that roasting before smelting may be tried.

### Siskiyou County.

G. T. Salsbury of Ashland, Or., working the Jillson mine near Hornbrook, claims he is mining and milling the low-grade ore at \$1.50 a ton.

### Trinity County.

La Grange mine, on Oregon Gulch mountain, 6 miles west of Weaverville, has been sold to an Eastern syndicate. P. Bouery has been manager for the French company owning the property. The mine has been yielding \$300,000 a year in gold profit for ten years and shows no sign of exhaustion. It was bought by the French company ten years ago for \$225,000. It has since spent \$600,000 in improvements that include the building of a flume 30 miles long and digging a tunnel 1½ mile in length through a mountain to convey water from Sturtevant fork to the mine. For hydraulicking, water is conveyed across a canyon in an inverted siphon.

### Tuolumne County.

A strike of good milling ore is reported from the Gold Bug mine, Big Oak Flat.—At the Red Jacket, Big Oak Flat, R. L. Shackleford is driving a crosscut to tap the main vein.—The Mohican mine, near Groveland, has started up after being shut down a month, because of the lack of wood and repairs to the machinery.—Arrangements have been made for the resumption of work in the Harvard mine, ½ mile west of Jamestown.

### Yuba County.

F. G. Cheney is building the two gold mining dredgers that will be constructed by the Marion Steam Shovel Works for the Marysville Gold Dredging Co. These two machines will be built near those in use at the Yuba Con. Goldfields and will build a continuation of the training walls that are to be constructed in the river for the Government.

## COLORADO.

## Boulder County.

The Copper Ocean M. & M. Co. has been formed. T. Lavridson, president; S. B. Kerr, vice-president; J. T. Cheney, secretary, and A. L. Dow, treasurer. The property which the company will operate is the Copper Ocean mine, 3 miles west of Lyons, and has been worked nearly all winter.

## Chaffee County.

The Stars and Stripes, near Turret, has been sold to the Pittsburg M., M. & D. Co. of Pittsburg, Pa. V. A. Lucier, W. D. Rhodaherger and J. Glashaw, three of the principal stockholders in the Pittsburg Co., have been at the mines. A wagon road will be made to the group and machinery put in.—H. Cocking is operating the W. & W., near Salida.—The Salida mine, 3 miles north of Salida, is taking out 1000 tons of shipping ore monthly. The copper leaching plant built near the property is not in operation. It is claimed that the process is not practical as its present stage, and alternations and improvements will be made. B. Ross of Denver, former manager of the Homestake on Gold Hill, Cripple Creek, is the president and general manager.

## Clear Creek County.

Operations on the Wilcox tunnel have been resumed, after a temporary shutdown caused by one of the Silver Plume transformers burning out. The management of the Waldorf Co. took advantage of the intervening time and overhauled the machinery, putting in two new compressors. The tunnel is in nearly 4000 feet. C. L. Tingle is superintendent.—A strike is reported in the Sceptre tunnel on Democrat mountain, by I. R. Clapper, 1900 feet from the portal.—T. Tyler, manager of the Duluth & Colorado M. Co., in Daily district, near Georgetown, reports that the Uncle Sam tunnel is in 270 feet. The Continental tunnel, started a few weeks ago, is in 60 feet and is encountering stringers of ore.

Foreman C. Garrett of the Stevens mine and mill at Silver Plume expects to have the mill running by the first of May, as the melting snow will provide plenty of water. The mill has been overhauled. Development work has been kept up in the mine during the winter. Connection will be made from the Stevens workings with the Tobin tunnel of the Waldorf properties on the East Argentine side of the mountain within a few months, and ore from the veins that have been opened in that tunnel can also be treated at the Stevens mill.—Preparations are being made for a mill at the mouth of the Wilcox tunnel.—It is reported that the owners of the Mammoth property in Brown gulch, near Silver Plume, will commence work, after several years' idleness. P. Kennedy, J. J. O'Neil and Leonard of Denver are the owners.

D. W. Shepard of Georgetown, manager of the Anglo-Saxon Mines Development Co., has completed a tramway for carrying ore material to a concentrating mill of 100 tons capacity to be built soon.—Work has been resumed on the Big Blue of Georgetown.—A strike is reported on the Mineral Chief, near Georgetown, in drifting on the vein from the Moline tunnel. A contract to drift 1000 feet west on the vein has been let to Nelson Bros., who propose putting in a compressor and drills and driving it with three eight-hour shifts. The property is under bond to the owners of the Kelley tunnel.

## Dolores County.

The Dunton Con. M. Co. is developing claims in the Dunton or Lone Cone mining district. Three 8-hour shifts are now being worked on the drift, which is in over 200 feet with a 160-foot raise to the surface, and 1000 feet from the mouth of the tunnel it is intended to make another raise of 200 feet to connect with tunnel No. 3. W. Wittle is manager.

## Fremont County.

(Special Correspondence).—It is understood that after a cessation for several months nearly all of the coal mines in Fremont county have started operations. The railroads have granted a reduction of 25 cents per ton for hauling coal and this reduced rate has given the industry an impetus to start up.

Florence, April 17.

## Giblin County.

E. S. Moulton reports high-grade ore at the Cotton mine of the Nemaha group on Boh Tail hill, near Central City.—The American National Bank has transferred to G. Aarons and J. H. Gower the Clay County mine in Lake district for \$8000.—The Cissler lode, Russell district, has been sold by E. E. Chase of Denver to L. & P. Sternberger.—Ore from the 600-foot east level of the Pittsburg mine in lower Russell district, operated by the Cashier G. M. & R. Co., shows a high value in gold, silver and copper.—Philadelphia owners are arranging to start up the Avon mill in Nevada gulch to treat the ores from their San Juan and Avon properties. The mill has been shut down since last summer because of failure of water for milling, it formerly being supplied by the Gunnell mine before the plant of the latter property was destroyed by fire. Nevada gulch will furnish sufficient water three months, and by that time it is expected that the Gunnell property will be operating again.—Rule & Trezise are shipping twenty tons per day from their lease in the 334 and 400-foot levels of the Protection mine of the Roderick Dhu property on the "Patch." It is reported that the main shaft, known as No. 485, is to be started again, and that an air compressor plant will be put in by the Roderick Dhu.

## Gunnison County.

W. S. Henderson has started work on the Belzora-Bassick group, near Pitkin.—The Jersey Blue mill, near Pitkin, is ready to start treating ore from the Cortland dump.—The Gray Eagle tunnel, near Pitkin, has been driven 200 feet by Wackerly & Smith.—The Lamphier group, west of Ohio creek, at Lamphier lake, has been sold to Eastern parties.—It is reported that the Sporting Times claims, near Pitkin, are to be worked by F. Schrott and associates. Operations had to be suspended on account of a large flow of water in the shaft, making it necessary to run a tunnel for drainage purposes.—Work on the Robert E. Lee tunnel, near Pitkin, has been delayed because of the heavy snows.—The Indiana G. & S. M. & M. Co., on McClellan

mountain, near Pitkin, will commence operations as soon as the snow melts sufficiently.

E. E. Connery and W. G. Baird of St. Charles, Mo., officers of the Continental Mines Co., at Vulcan, have been arranging for the summer's work.—A rich strike is reported in the Gold Links tunnel, above Ohio City. The ore is in 1200 feet.—Near Italian mountain, at the head of Taylor river, and at the X-10-U-8 mine, G. Hubbard is ready to start shipping ore.

## Lake County.

J. L. Jenkins has started work on the Trilby group, on the southern slope of Gold hill, in Black Cloud gulch, near Twin Lakes.

At the Murphy shaft, Rock hill, Leadville, the main drift has not reached the end of the ore shoot.—Work has been resumed on the Sullivan and the Lucky Joe shafts on the Nisi Prius ground.—J. McAllister has resumed underground work on the Smuggler, Iron hill, Leadville. A gallows frame has been put up.—The Fanny Rawlins, Breece hill, Leadville, is shipping 50 tons daily of good grade ore and carrying on development work in new ground.—The Elk people are still working on a small streak of rich ore and shipping 150 tons per month.—The Highland Chief is sending out 25 tons daily of siliceous ore.—The new pumps, extra boilers and connections have been completed at the Penrose, at Leadville. Three pumps are in the shaft, with a combined capacity of 1950 gallons per minute. The management expects to lower the water 5 feet daily, at which rate it will take twenty-five days to reach the bottom of the shaft. When this is reached a compound station pump will be put in to handle the extra flow of water. There are still 20 feet to be sunk before the shaft is deep enough to drift to the Coronado. When sinking is completed the shaft will be 50 feet deeper than the Coronado, and all of the water from that property will be diverted to the Penrose, which will be used as the main pumping shaft for the two mines. This will drain the Coronado and permit of handling the ore at reduced cost. The Coronado is shipping 50 tons daily, which comes from development work. When stoping begins the output will be 250 tons daily.

## Ouray County.

The Joker tunnel of the Red Mountain R., M. & S. Co., near Ouray, is past the 1000-foot mark. Superintendent Aston has charge.—The management of the Treasury tunnel, in Red Mountain district, hopes to start its full force. The property has not been working for several weeks on account of lack of coal, as the roads have been in very bad condition.—The Revenue tunnel is increasing its force.—The Tempest Apex Co. is taking out good ore from the Mickey Breen. The mill will be started soon.—Arrangements are being made for building a 40-stamp mill on the Security G. M. Co.'s property on Cow creek, near Ouray. A wagon road is being built from the millsite to pine timber for the mill and mine buildings.—The tunnel of the Ouray Con. M. Co. at Ouray is being driven by Superintendent J. H. Tumhach at the rate of 2½ feet per day, hand work. The tunnel is in 400 feet and is 6x8½ feet.

## San Juan County.

(Special Correspondence).—Plans have been drawn and the contract closed for a 500-ton concentrating mill to be built at Animas Forks, 12 miles north of Silverton. This mill will handle the ore from the old Sunnyside Extension mine, now known as the Gold Prince, W. Z. Kinney, manager. The starting of this enterprise will have a good effect on other companies throughout the State that are contemplating the erection of reduction works. It is understood an aerial tramway will also be built to convey the ore from the mine to the mill. Silverton, April 17.

The air compressor has been put in for the power drills at the Ruby Basin M. & M. Co.'s crosscut, destined to tap the Tornado of North Lookout mountain, near Silverton.—W. N. Sisson, superintendent of the Northern Light M. Co., Boulder mountain, near Silverton, thinks the company will start in May opening the Ariadne and driving a crosscut from the level of Cement creek which will intersect consecutively all the claims of the group.

Manager J. B. Warner announces that just as soon as the snow disappears the Silver Ledge properties, near Chattanooga, will be worked. The product of this property is impregnated with zinc, and the greater part of last season at the mill was spent in attempting to get at the proper way of separating zinc and iron, so that these two products might be saved in a marketable form. Late in the season the problem was solved when a system of electrical separators was put in. At that time the mill was being run by water power, and in November, owing to the general freeze-up, operations had to be suspended and the mill has stood idle ever since. This year steam and electrical power are to be put in and the concentrator will be enabled to run the year through regardless of weather.

## San Miguel County.

The Ophir Con. group at Ophir Loop, 14 miles from Telluride, plans to remodel the 50-stamp mill to treat tungsten mineral.—The Japan group in Savage basin have finished the connection between the upraise driven from the lower workings and the bottom of a shaft sunk from the lower level of the upper workings, draining the property of 3,000,000 gallons of water and establishing good ventilation. It is the intention of the company, before starting to work the mines, to determine by tests the method best adapted for the treatment of the product.

## Summit County.

The Old Union M. & M. Co. of Breckenridge has started its first stope from the main tunnel at 350 feet from the mouth of the tunnel. A ditch is now being built to supply the new 100-ton capacity mill with water.—N. J. Coleman has run the Silver Dick tunnel, on the Red Mountain side of the Silverton-Red Mountain Railroad, ½ mile below Chattanooga.—The Brooklyn, near Chattanooga, under the management of T. Manion and E. A. Ormland, is doing a little development.

The Laurium group, near Breckenridge, which is developed by a 1300-foot tunnel, is reported as looking so

favorable that the owners are considering building a 30-ton concentrating mill near the entrance to the tunnel. The property is owned by Forman & Walker and is near the middle of the Mount Baldy and Nigger Hill lead-silver zone.—The force at the North American and Mary Verna properties, in the Ten Mile district, near Breckenridge, is to be increased as soon as necessary room in the mines can be made for additional miners.—The French Creek tunnel, near Breckenridge, is under contract to E. T. Brooks.

## Teller County.

Underground connection has been made between the New Haven and Jo Dandy mines on Raven hill, Cripple Creek.—Hoisting machinery and machine drills are to be put in the shaft of the Home Lode of the Cedar Hill G. M. Co. of Cripple Creek. The shaft is to be sunk to a depth of 200 feet, being down 60 feet.—Manager Van Fleet of the Montrose lode on Ironclad hill is putting in a new compressor and machine drills.—The cyanide mill that is being operated by the R. E. A. & A. Co. at the Wild Horse mine, Cripple Creek, is treating nearly 100 tons per day. Most of the ore now being treated at the mill is being taken from the large dump at the mine.—McGee and associates, operating under lease the Mohawk Bell and Twin Sisters claims on Raven hill, are now making regular shipments of a good grade of ore. The operators have opened up three distinct ore shoots in different places in the drifts at a depth of 140 feet, and each body is ranging from 2 to 5 feet in width. They intend sinking the shaft.—Jackson and associates, operating under lease the Mary Nevins property on Rosebud hill, are putting in an air compressor, and expect to sink the shaft an additional 100 feet. The shaft is down 250 feet.—The west shoot at the 900-foot level of the Elktion at Cripple Creek is being developed.

—The Blue Bird Co. on Bull hill has given contract to A. Denslow and J. J. Acton of Cripple Creek to drift 300 feet and upraise 50 feet at the 1300-foot level so as to make an air connection at the northern extremity of the Portland estate. President E. S. Johnson plans to provide an outlet for the carbonic acid gas recently encountered at the 1300-foot level.—Molvany and associates, leasing a block of the Ajax on Battle mountain, will put machinery on their ground to increase the tonnage.—The Golden Wedge on Beacon hill is being equipped with new machinery to facilitate sinking another 100 feet.—During March the total shipments leaving the Stratton's Independence mine amounted to 5500 tons.—Lessee Walden and associates, operating the main workings of the Rose Nicol property on Battle mountain, are sinking the shaft another 100 feet.—Operations have been started on the Jefferson property at Victor by W. H. Camp of Colorado Springs.—The Milwaukee Mutual M. Co., operating under lease a block of the Mabel M. property, owned by the Gold Dollar Con. Co., is sending out regular shipments from the body of ore recently opened up.—Operations have been resumed on the Pinnacle mine on Bull hill by G. Glenn of Cripple Creek.—It is reported that the officials of the Portland G. M. Co. had decided not to lease the big dump at the No. 1 shaft, but to treat it at their own mill at Colorado Springs.

## IDAHO.

## Blaine County.

J. B. Gieske, the president of the Idaho Con. M. & D. Co. at Soldier, has appointed W. Teasdale as superintendent, who has started work upon the company's Golden Rule group in the Big Smoky region.—F. W. B. Johnson, superintendent of the Wood River Zinc Co., expects the new mill, near Halley, to be ready by May 15.

The Northwestern M. Co., under the management of R. T. Tustin, is working a large force on the Weber property driving a crosscut tunnel to tap their vein at depth, which, when completed, will be 1700 feet in length. They expect to build a mill this season. The mine is in the Muldoon district, 20 miles east of Bellevue.—The Argosy M. Co. is doing considerable work in the same district.

## Boise County.

J. H. Emery, manager of the Gold Coin M. Co., near Idaho City, says a mill will be put up at the mine this summer, and an electric plant will be put in on More creek to furnish power for mill and mine.—The Ben Solomo ditch, 7000 feet long, will be enlarged to carry 800 inches of water and give a pressure of 129 feet. They intend to run a tunnel on the ledge from Washington gulch.—Blaine & Co. of Placerville have let the contract for the excavation for their new dredge which is to be 85x135 feet and 7 feet deep.—D. Coughanour and D. Tew of Quartzburg intend to put a mill on the Belshazzar mine. They are putting men to work on the road to the mine.—The Iowa mine and mill near Placerville will start up soon.

O. N. Callender, of Emmett, president of the Buckeye M. Co., of Pearl, reports that the company will sink an incline shaft on the ledge.

## Custer County.

J. N. Wallace, of Boise, president of the Van Anda M. & M. Co., reports striking a good ledge in the tunnel of the Van Anda, 3 miles from Custer, 600 feet from the tunnel portal.

## Elmore County.

M. Jacobs, of Boise, reports that Speer's American Exchange will put in a 100-ton cyanide plant at the Petit mine near Atlanta. L. W. Speer and party are expected at Boise to inspect the mine.

## Shoshone County.

C. Manley, manager of the Blackhorse mine, near Murray, reports that the lower tunnel is in nearly 150 feet, and is expected to reach the ledge by May 1, when regular shipping will be commenced.—The Monarch mill at Murray is shipping concentrates regularly. E. P. Spaulding is manager.—The main tunnel of the Majestic M. Co. of Burke is in 220 feet. C. K. Cartwright, superintendent of the Burke mines of the Federal Co., and J. C. Browne, superintendent of the Hecla mine at Burke, are interested.—The War Eagle M. Co., 1½ mile from Wallace, on the west fork of Placer creek, have run their tunnel 1600 feet on the War Eagle.

G. R. Trask is the engineer for the company and acting as manager.

The Morning, Hecla and Frisco mines' statements for 1904 show that the Morning suffered during the year on account of shutdowns due to insufficient water supply. The Hecla surpasses its record of any former year; the Frisco was worked only by leasers and not upon the scale of former years. The Hecla report was: Tons shipped, concentrates, 13,670; gross yield, \$671,251.89; transportation, cost, \$103,703.01; reduction, cost \$34,401; construction, betterments and repair, etc., \$21,859.56; mining and milling, \$304,277.24; total expense, \$463,740.81; net profit, \$207,510.44. The Morning report was: Tons produced, 235,775; gross yield, \$1,292,903.30; mining and milling, \$474,406.12; treatment and transportation, \$591,197.74; improvements, \$59,194.58; total expense, \$1,117,798.44; net profit, \$175,106.86. The Frisco report was: Tons ore and concentrates, 1434; gross yield, \$78,167.19; mining and milling, \$35,422.59; general expenses, \$5,773.76; transportation, \$11,572.00; reduction, \$18,534.39; improvements, \$390.66; total expenses, \$71,693.42; net profit, \$6,473.77.

#### Washington County.

C. W. Jones reports the Ladds Metals Co. is preparing to rebuild the smelter at Landoro and put in a reverberatory furnace. It has 4000 tons for treatment on hand.—D. C. Nevin, president of the Iron Springs Co., is in the East, but is expected to arrive shortly. A portion of the mill machinery has already arrived. The company will build a cyanide plant with a 200-ton capacity.—F. T. Mathias & Sons have started work at Grouse creek.

### MICHIGAN.

(Special Correspondence).—The production of the Michigan mines for March was 19,300,000 pounds of refined copper.—At the Adventure Con. mine 18½ pounds of refined copper are being obtained per ton of rock treated. Drifting east from No. 3 shaft on the Knowlton lode at the eighth and ninth levels is opening good ground. The Adventure is employing 250 men and the daily rock shipments average 375 tons.—The Michigan mine is shipping 480 tons daily to the Mass Con. stamp mill at Keweenaw bay, with prospects for increase when the mill is improved.—Equipment for the addition to the Champion stamp mill at Freda is being put in. The experimental outfit will consist of crushers and rolls and necessary adjuncts for concentration of values, with half the capacity of the simple compound stamphead.—The Wolverine Co. is repairing the stamp mill at Gay, on Traverse bay, Lake Superior. The Wolverine mill contains two heads and has been operating continuously for two years without repairs.—The permanent duplex cylinder double conical drum hoisting engine at No. 2 shaft of the Mohawk mine is being used. No. 5 shaft is down 100 feet and will be continued to a depth of 175 feet, and a drift run north to connect with the opening south from No. 4 shaft on that level.—Operations have been resumed at the Franklin Junior and Franklin branches of the Franklin M. Co. after an idleness of twenty days caused by the strike of underground employees. No concessions were granted to the men by the company and they returned to work under the same terms as before. It is likely that the Franklin management will begin diamond drill exploratory work to locate the southern extension of the Kearsarge amygdaloid lode.—Navigation has opened at copper ports.—Arrangements have been made by the Quincy M. Co. for rebuilding its compressor at No. 6 shaft. It will be altered from a single to a two-stage machine, raising the capacity from 50 to 100 drills.

Calumet, April 15.

### MISSOURI.

#### Jasper County.

(Special Correspondence).—Considerable work is being done on Short creek, at Cave Springs, and in the Ozark range near Aurora.—H. Smith of Joplin, who is mining on the Missouri Lead & Zinc Co.'s land near Joplin, has opened up a fine prospect in an old shaft and is taking out good ore. He intends building a mill.—Hancock & Co., of Joplin, who have a lease on forty acres of land east of Joplin, have opened up a lead mine at a depth of 120 feet on virgin ground.—P. H. Puckett of Galena, Kansas, and N. P. Road of Joplin have resumed operations at their mine on the Brooks land near Zincite. The mine is producing about twenty-five tons of ore weekly. A new 10-inch lift pump will be put in.—C. L. Crockett & Co., of Joplin, who are mining at Tuckahoe, have opened up a very large face of ore in a new shaft and will build a new mill.—Holmes, Cape & Rogers, of Joplin, have opened up a good mine in the Peacock district and will commence a new mill.—There are seven mills being built in the Badger district. The Kansas Natural Gas Co.'s pipe line passes through the camp and will supply the mills with a cheap fuel.—B. M. Robinson, of Joplin, has finished drilling a number of holes on S. H. Claycomb's land near Joplin, and is sinking a shaft.

Joplin, April 17.

### MONTANA.

#### Lewis and Clarke County.

The Red Bird M. Co., of Helena, is shipping from the Red Bird and Reliance. The Red Bird will be developed by sinking another 100 feet from the 350-foot level. On the Reliance the winze is being sunk in the ore. The company expects to begin operations in the Copper Hill, sinking another 100 feet.—The mill on the Whitlatch-Union, south of Helena, has been started up by Canoll & Martin. Unwatering the mine is progressing so that the property will soon be open for exploration. The new shaft, which has been sunk 42 feet, will be sent down another 100 feet, and crosscuts run.

#### Madison County.

Operations will soon be resumed on the McVey property, owned by the Minnesota & Montana Co., at Sand creek. The 250-foot shaft is being repaired preparatory to sinking an additional 200 feet.—It is reported that, in Alder gulch, near Virginia City, the Alder Co. is preparing to start up the mill and concentrator at the

Kearsarge properties and that the entire sixty stamps will be in operation.—At the General Shafter mine, of the Dakota M. Co., near Virginia City, a 5-stamp mill and concentrator will be ready to start.—The two dredges of the Conroy Placer M. Co. will be running as soon as the water starts through the Alder creek again.

It is reported that work will be resumed on the Easton mine, near Virginia City, by Superintendent J. H. Pankey. The Easton mill will be closed down for repairs April 25 to be overhauled.—It is stated that the Alder Gulch M. & M. Co., near Virginia City, is preparing to start up the mill and concentrator at the Kearsarge properties. The General Shafter mine, of the Dakota M. Co., is undergoing alterations, and a 5-stamp mill and concentrator will be ready to start soon. The two dredges of the Conroy Placer M. Co. will be running as soon as the water starts through Alder creek again.—Operations will be resumed in the McVey property of the Minnesota & Montana Co., at Sand creek. A 250-foot shaft is being repaired with a view to being sunk 200 feet.

#### Missoula County.

The Cape Nome, 19 miles east of Missoula, has started shipping copper ore to the East Helena smelter. New machinery is to be put in.

#### Silver Bow County.

The Parrot mine at Butte has been closed through an injunction issued on application of the Nipper Con. Copper Co., in an action instituted charging that the Parrot Silver & Copper Co.'s agents were extracting ores from the Nipper vein on various levels below the 1000 station and hoisting it to the surface through the Parrot shaft.

### NEVADA.

The Supreme Court has upheld the act of 1903 making it a misdemeanor for employees to work longer than eight hours in one day in underground mines, smelters, and in all institutions for the reduction or refining of ores or metals. The opinion was handed down in the case of the State of Nevada vs. P. Kair, coming up from the county of Lyon on a petition for a writ of habeas corpus. Kair was employed at Dayton in a wet crushing quartz mill and was fined \$100 in the township court for working a longer period than eight hours in one day.

#### Esmeralda County.

At the Florence mine, near Goldfield, F. Oliver, the superintendent, has started timbering the shaft to the 200-foot level, preparatory to sinking an additional 50 feet. Grading has commenced for the new ore house. A new gallow frame has been ordered.—A. H. Mayne is developing the Goldfield Jim on the northwest slope of Columbia mountain and intends to build a cyanide plant.—The Hiawatha M. Co., of Goldfield, is operating a lease on the Silver Pick property. The working shaft is down 110 feet.

Topographers and geologists of the United States Geological Survey will be at work during the coming summer south and east of Tonopah. A party of fifteen under the direction of R. H. Chapman will make surveys for three topographic maps. Two of these maps will be detail maps by W. Stranaban, one of the Goldfield district, 23½ miles southeast of Tonopah, and one of the Bullfrog district, which is 60 miles south of Goldfield. The Goldfield map will cover 40 square miles and will be drawn on a scale of 2000 feet to the inch. Triangulation and leveling will be carried from Owens valley to get control for the Bullfrog map, which will also be drawn on a scale of 2000 feet to the inch. The third map will be a reconnaissance map 120 miles long by 90 miles wide, south and southeast of Goldfield. It will include Goldfield in its northwest corner. The heights and shapes of all the mountains will be shown, as well as all roads, all springs, and water holes. The reconnaissance map will include part of Death valley. Levels for the control of all this work are being made from Mohave by a topographic party under R. H. Farmer. It is hoped that there will be an opportunity of running a level line to find the correct elevation of Death valley. E. M. Douglas, chief of the western section of topography, has computed that the lowest point in the valley is 450 feet below sea level. Geologic studies in these same Nevada areas will be prosecuted during the summer under the direction of J. E. Spurr.

#### Enreka County.

S. W. West is shipping 150 tons daily from the West M. Co. iron deposits, 6 miles west of Palisade, to the American S. & R. Co.

E. Hoffman, superintendent of the Carisa M. Co. at Eureka, reports eight sets of lessees working on ores. The main shaft is to be sunk to the 1200-foot level before another level is established.

#### Lincoln County.

After five month's work A. B. Hall has cleaned up the tailings pile at the Quartette river mill, near Searchlight, treating 9000 tons in the cyanide plant. The sampling room, attached to the mill, is being torn down and the material taken to the mine.—G. M. Rose and J. C. Tipton have been at Searchlight making arrangements for putting in a cyanide plant to work the tailings of the Southern Nevada mine.

#### Storey County.

The Comstock Pumping Association will repair the Sutor tunnel and its north and south lateral branches on the Comstock lode and equip them with drain pipes to carry off the water that is pumped from the lower levels of the Comstock mines. L. M. Hall, superintendent of the pumping association, will take charge of the work. The purpose is to have the mines drained and repaired jointly. The expense will be borne by the several companies.

### NEW MEXICO.

#### Colfax County.

The 150-foot mark has been passed in the Deep Tunnel mine, near Elizabethtown, and a contract has been let for 100 feet more work by McIntyre Bros.

There will be an abundance of water in the Elizabethtown and nearby districts. Among those at Elizabethtown preparing for hydraulic work this summer are: J. Lowrey in Humburg gulch; H. Kaiser, Willow creek; F. Wilkinson, B. Geskie and M. Mead, Ute creek; Horner Bros. and B. Geskie, South Ponil placers.

#### Grant County.

In the Burro Mountain mining district, 14 miles southwest of Silver City, the St. Louis mine is producing a carload of concentrates daily. The property is managed by T. Carter.—The Colorado Fuel & Iron Co. is getting out 600 tons of iron ore per day from its mines in the Fierro district.—J. W. Bible, manager of the Nevada Copper M. Co., in the Hanover district, has 100 men developing the mines.—The Santa Rita Copper M. Co. is producing three carloads of copper ore per day, which is shipped to El Paso smelters. J. Deagan is the manager.—The Comanche Copper & Smelting Co. of Silver City has purchased the Hearst properties in the Pinos Altos district, and the arrangements are perfected for the construction of a narrow gauge railroad 9 miles from Silver City to Pinos Altos.

Blackburn & Campbell of Lordsburg and D. C. Kase-man of Shamokin, Pa., have taken a bond and lease on the Nellie Bly, south of Lordsburg. The workings are at water level and it will be necessary to put in a pump. A bond and lease was also taken by the same parties on the Robert E. Lee, adjoining the Nellie Bly. The company is to be incorporated as the Pyramid Peak Copper Co.

#### Sierra County.

The Empire G. M. & M. Co. is building an assay office and warehouse at Cold Springs. The company intends to rebuild the smelter at Kingston.

The deal for the Union and Esperanza claims at Shandon, in the Pittsburg placer district, has been closed by B. Silva with the Union Esperanza M. Co., which company is making arrangements for the installation of a 400 H. P. hydraulic plant.

#### Union County.

The Coronado C. Co. has acquired interests in Peacock canyon, northeast Union county, in the Cimarron River valley.

### OREGON.

#### Baker County.

The Oregon M. & D. Co. are completing a cyanide plant to work the tailings from the Virtue mill, near Baker City. It is planned to scrape the tailings to a common center, using ordinary road scrapers, and then, by means of an elevator, convey them to the vats. It is believed that this can be done at a cost not to exceed 6 cents per ton.—A. Larsen of Greenbourn reports striking the vein on the property of the Little Salmon G. M. Co., 240 feet from the mouth of the tunnel.

#### Grant County.

Superintendent N. F. Heath of the Standard mine, near Prairie City, says that Manager H. H. Nicholson has ordered a gasoline engine, dynamo and electric drills.

J. R. Cassin of Spokane, Wash., says that work will be started at the Alamo mine, near Granite, during May.

Superintendent W. E. Gifford of the Present Need, near Comer, reports a strike of ore.—Manager J. W. Messmer of the Prairie Diggings mine, near John Day, plans reopening the property.

#### Josephine County.

P. B. Wickersham and J. E. Loomis have a lease on a placer below Galice and are working it steadily.

#### Lane County.

D. H. Weyant is working the Simmons paint deposit, 2 miles from Walker.

### SOUTH DAKOTA.

#### Lawrence County.

The Elliptic M. Co., in Miller gulch, northwest of Deadwood, is down 230 feet in its shaft.—It is reported that the reorganization plans of the Clover Leaf M. Co. have carried at the special meeting at Beulah, Wyo. By the action at this meeting the capitalization of the company is changed from 12,000 shares of \$100 each, to 2,500,000 shares of \$1 each.—Mechanical stokers are proving satisfactory to the Homestake Co., at Lead. A year ago several of these stokers were installed in the Lead mill and after a year's test the company has decided to put them into the cyanide mills at Lead and in Gayville. This mechanical device gives more perfect combustion, reduces the cost of fuel and enables one man to do the work required of several when the old style furnace feed was employed.

### UTAH.

#### Salt Lake County.

The Bingham Bulletin gives the following as the number of men employed and the daily production of Bingham mines:

	Men.	Tons.
Highland Boy.....	330	850
Yampa (mine and smelter).....	300	450
Boston Consolidated.....	85	200
Bingham-New Haven.....	45	75
Utah Apex and Red Wing.....	25	700
Utah Copper (mine and mill).....	175	200
Ohio Copper (mine and mill).....	270	500
Silver Shield.....	25	...
Commercial.....	25	75
Dalton & Lark.....	275	300
Fortuna.....	45	30
Butler-Liberal.....	10	...
Phoenix.....	35	30
Various small properties.....	100	25
Totals.....	1,967	3,435

E. A. Wall has an option and commenced work on the Starless group at Bingham, owned by the Bingham-Oquirrh Co.—Superintendent McCree of the Red Wing mine at Bingham is putting in a power drill and 6-drill air compressor plant. The Red Wing tunnel is in 800 feet and will be driven 3000 feet.

The Ohio Copper Co. of Bingham will crosscut to the Bettles ledge from the 300-foot level.

#### Summit County.

To attain the depths at which it is believed the main

ore bodies of the King Con., of Park City are to be found, the management of the properties has been authorized to proceed with the installation of a Corliss engine and pump, and with this in position, says Man-S. Spiro, sinking will following. The shaft, which is down 800 feet, will be sunk to the 900-foot level, where exploratory work will begin.

#### Utah County.

The Steele mining property at the head of American Fork canyon, and owned by T. E. & R. A. Steele, will be worked this season.

### WASHINGTON.

#### Snohomish County.

Manager Morris of the Bunker Hill Co.'s Copper Bell, near Index, expects that the improvements on the experimental mill will be completed by May 1. New concentrators have been put in and steam power replaced by electricity.—A. S. Chase has resumed work on the Sunrise mine, 6 miles above Silverton.

A gasoline engine and steel track is being put in by the Buckeye Copper Co. at Index. The management will start a crosscut to be used as a permanent tunnel.—A dynamo and motor are being put in at the Copper Belle at Index to operate the mine and mill machinery.

### WYOMING.

The Copper Rock G. M. & M. Co. of Encampment has started a new shaft 4½x9 feet in the clear, which they propose to sink 500 feet. The old prospect shaft, which was down over 200 feet, and on an incline, was found too small for a working shaft. E. Young is superintendent. In the Encampment district the Copper Blossom claims near Station Three is operated by the Copper Age Co. under the management of C. W. Miller, Jr.

### FOREIGN. AUSTRALIA.

Production of gold in the Australian States and in New Zealand for 1904:

	Fine Ounces.
Victoria.....	771,298
New South Wales.....	269,817
Queensland.....	624,917
South Australia.....	17,913
Western Australia.....	1,983,230
Tasmania.....	60,000
Total Commonwealth.....	3,727,175
New Zealand.....	467,647
Total.....	4,194,822

#### Western Australia.

The West Australian Mining Industry reports that West Australia is partitioned into six land divisions. All north of 19½° south latitude is known as the Kimberley division. The Northwest is coastal, with its southern boundary at the 23d parallel, its eastern boundary being the 119th meridian of longitude south of the 23d parallel of latitude, and the 122d meridian north of that parallel. Adjoining the Northwest division on the south, and also reaching out to the 119th meridian, is the Western division, which follows the coast as far south as the Murchison river, and then 100 miles from the seashore, runs down to within 20 miles of the 29th parallel. The whole of the coastal area south of the Western division, to the intersection of the 124th meridian and the 33d parallel of latitude, forms the Southwest. The remainder of the coastal line belongs to the Eucla division, which east of the 125th meridian reaches to the 30th parallel of latitude, while farther west its northern boundary is the 32d parallel, its stretch westwards being to between the 123d and 124th meridians of longitude. The whole of the remainder of the State constitutes the Eastern division. The mining fields are situated thus: Kimberley goldfield, in the southeastern portion of the Kimberley division, reaching up to the 16th parallel in the northeast corner, and to the 18th on the northwest corner, and on the west bordered by the 126th meridian. Pilbarra goldfield in the Northwest, running not quite to the northern and eastern boundaries of the division, and on the west following the course of the Yule river to the coast. In the south it takes in a small portion of the eastern land division. It is divided into two districts, Marble Bar on the north and Nullagine on the south. West Pilbarra goldfield, adjoining the Pilbarra goldfield on the west, with the Fortescue river as its southern boundary. Ashburton goldfield, on the Ashburton river, partly in the Northwest and partly in the Western division, extending inland from a point 150 miles distant from the mouth of the river. Gascoyne goldfield, in the Western division, adjoining the Ashburton field on the south. Peak Hill goldfield, mainly in the western portion of the Western division, but also extending some distance into the Eastern division. Murchison goldfield, south of the Peak Hill field, and, like it, but to a less extent, encroaching on the Eastern division. It is divided into four districts—Nannine in the north, Mt. Magnet in the south, and Cue and Day Dawn between them. The Day Dawn district, though still kept distinct in the official returns, is practically merged in that of Cue, all the business of the district being done in the center of that district. Yalgoo goldfield, adjoining the Murchison on the south, mainly in the Western land division, but on the south stretching some distance into the Eastern division. Northampton mining district, in the Southwest, extending a little distance into the Western division. The coast forms its southwestern boundary. Yandanooka mining district, in the southwest, about one-third of the way from Geraldton to Perth. Collie coalfield, in the southwest of the Southwest division. Donybrook goldfield, still further southwest, 131 miles south of Perth. Greenbushes tinfield, southeast of the Donybrook goldfield, in the same division. Phillips River goldfield and mining district, on the southern coast, partly in the same division as the Donybrook (the Southwest), and partly in the Eastern division. Dundas goldfield, stretching to the southern boundary of the Eastern land division, and lying between the 120th and 123rd meridians. Like all those that follow, it is entirely in the Eastern division. Yilgarn goldfield, adjoining the Dundas on the northern portion of its western boundary and reaching north to

about the 30th parallel. Coolgardie goldfield, adjoining the Yilgarn field along the 120th meridian and on the south the Dundas field. It is divided into the districts of Kunanalling (on the north) and Coolgardie. East Coolgardie goldfield, on the north of the eastern portion of the Coolgardie field. Broad Arrow goldfield, on the northwest of the East Coolgardie field, on the west adjoining the Coolgardie field. Northeast Coolgardie goldfield, stretching east of the Coolgardie, East Coolgardie and Broad Arrow fields to the 125th meridian and on the south adjoining the Dundas field. It is divided into the districts of Kanowna, Bulong and Kurnalpi. North Coolgardie goldfield, reaching from the 125th meridian along the northern boundaries of the Northeast Coolgardie, Broad Arrow, Coolgardie and Yilgarn fields to the Yalgoo field, and in the northeast running to a point where the Yalgoo, Murchison and East Murchison fields meet. It is divided into the districts of Ullaring, Menzies, Niagara and Yerilla. East Murchison goldfield, bounded on the west by the Peak Hill and Murchison fields, on the north by the 26th parallel, on the east by the Mt. Margaret field and on the south by the North Coolgardie field. Mt. Margaret goldfield, reaching from the 26th parallel to the northern boundary of the North Coolgardie field on the 29th parallel and bounded on the east by the 125th meridian. It is divided into three districts—Mt. Malcolm (in the southwest corner, where the field runs in south of the East Murchison field), Mt. Morgans and Mt. Margaret.

### BRITISH COLUMBIA.

#### Boundary District.

After July 1, 1905, the bounty paid by the government on lead ore exported will cease. The St. Eugene has been getting a heavy percentage of the total lead bounty, and all of the export bounty, getting in March \$20,000. Local smelters with lead stacks are hard pressed for ore. The tonnage of the St. Eugene for the past month, except less than a fifth, went abroad—2300 tons to Germany and 800 tons to Belgium.—H. Shallenherger of Spokane, Wash., has started work on the Crescent mine, 2 miles from Greenwood.

Boundary shipments for week ending April 15 were:

Mine.	Tons.
Granby Mines.....	11,350
Mother Lode.....	2,592
Brooklyn.....	3,187
Rawhide.....	919
Mountain Rose.....	232
Oro Denoro.....	165
Winipeg.....	150
Stemwinder.....	450
Skylark.....	30
Last Chance.....	25
Total for week.....	19,050
Total for year.....	267,113

#### Lardeau District

Navigation has been opened on Trout lake, and this means a resumption of business in the Lardeau.—A Minnesota syndicate proposes driving a tunnel 4000 feet to tap the ledges of the Silver Cup, the Nettle L. and the Triune. Surveying has been commenced.—D. G. Forbes, who formerly had charge of the Silver Cup mines, has resumed his place.—Development work on the Lucky Boy is producing considerable ore. The final payment for the property has been made to J. W. Westfall and associates, who sold it to the present owners for \$16,000.—A Nova Scotia syndicate has been operating a property on Surprise creek.—O. Nelson and associates have bonded the Bonanza group for \$18,000.—The Mohican property, operated by the Cariboo Creek Development Syndicate of Rossland, will resume work when the snow melts.—At Camhorne, on the Eva group, a new body of ore has been uncovered and is being crushed in the mill.—As soon as the Great Northern Mines gets its affairs rearranged the intention is to increase the stamp mill at Camhorne from ten to twenty stamps. It will also put up a stamp mill at Poplar for the reduction of the ores of the Swede group and the Lucky Jack.

#### Rossland District

The tonnage of ore shipped from and crushed at the Rossland mines for the week ending April 15 and for the year to date was as follows:

	Week.	Year.
Le Roi.....	2,050	40,180
CenterStar.....	1,643	26,903
War Eagle.....	1,170	18,560
Le Roi Two (milled).....	400	1,600
Le Roi Two.....	120	3,353
White Bear.....	120	1,075
White Bear (milled).....	100	2,700
Jumbo.....	100	3,325
Spitzee.....	270	3,254
Velvet-Portland.....	100	1,577
Totals.....	5,753	102,357

#### Vancouver Island.

The Britannia mines, Howe Sound, will ship ore and concentrates to the Crofton smelter, Osborne bay. G. H. Robinson is managing director of the Britannia Copper Syndicate. The deal calls for the delivery of the entire tonnage of the Britannia for treatment at Crofton and is to last during the life of the Britannia. The minimum shipments are to be 250 tons per day, but it is expected that the mine will be shipping 500 tons per day as soon as it is in running order. The shipments will start about June 1 and the smelter will start about six weeks later. Crofton has a three-furnace plant capable of handling 700 tons a day. In addition it has two stands of copper converters of 1000 tons daily capacity. J. Breen will continue as head of the Crofton, and H. C. Bellinger will be consulting metallurgist for the Crofton and Yampa smelter at Bingham, Utah. The Britannia is completing its 600-ton concentrator and its 3½-mile tram. The Britannia ore and concentrates together make a self-fluxing charge.

### MEXICO.

Under the plan of currency reform in Mexico is the tariff for the collection of assay and melting dues. Silver bars of which the fineness is at the lowest 100-thousandths: For each bar weighing not more than 53 kilograms, \$1.50; for each 10 kilograms or fraction of 10 kilograms, \$1.50. Gold bars or mixed gold and silver

bars whose fineness is at least 100-thousandths: For each bar weighing not more than 35 kilograms, \$2.50; for each 10 kilograms or fraction thereof in excess, \$2.50. Pigs of lead, copper or any other metal: For every 5 tons or fraction thereof contained in the lot, \$2.50. Artificial sulphides, concentrates, mattes, ores and tailings: For each lot, according to class, including the sampling, \$3. For articles of the goldsmith's or silversmith's art: For each assay, including hall mark, \$1. Melting dues: For each kilogram or fraction thereof before melting, 10 cents. In no case will less than a dollar be charged.

Under the new mining law, which will go into effect May 1, the import duties, payable on all machinery for mining operations or for metallurgical establishments will be returned to the importers within six months from the date of the last importation. The regulations governing the return of these duties are as follows: "The ordering mining or metallurgical concern will, at least twenty days prior to the arrival of the machinery, furnish the General Custom Bureau with a general description thereof, the locality in which it is to be installed and the name of the custom house through which it is to be imported, to the end that said custom house may receive in due time from the Bureau proper notice and instructions. When the importation is effected there must be presented to the custom house the consular invoice or invoice request as may be required; a copy of the private invoice with specifications of the packer, and a plan or drawing of the machinery in question. If the definite installation of the machinery shall have been completed within six months counted from the date of the importation of the last shipment, the Department of Finance will order the refundment of the duties collected upon receipt of a report from an expert appointed by the Custom Bureau to the effect that the machinery has been definitely installed and that it is the same as that referred to in the specifications, drawings and invoices mentioned in the foregoing sections. In order to obtain exemption from duties it is not necessary that the importation should take place in a single shipment, but when once all the pieces composing the machinery shall have been imported, an operation that must always be effected through one and the same custom house and in a period of time not exceeding two months, the other loose pieces or repair pieces that may be imported separately will be subject to the respective duties without any claim to refundment."

#### Chihuahua.

W. Adams, in describing the mines of Santa Eulalia, says that the Las Animas shaft is down 225 feet. The owner, J. Aguirre y Nevares, is building the first Weher gas generating power plant on the field, with a capacity of 25 H. P. The manager of this property is C. Aguirre.—The Mina Vieja shaft is down 1000 feet; 22 H. P. gasoline engine hoist; manager, J. Mitchell.—La Esmeralda, owned by M. Gameros, P. Gomez y Campo manager, has its shaft down 125 meters; 12 H. P. gasoline hoisting plant.—The shaft of La Paracionera, Qualey Bros., is down 1200 feet; 100 H. P. plant; and Providencia shaft is down 400 feet; 25 H. P. engine and plant; J. Murray is superintendent.—The Santa Rita shaft, owned by the Chihuahua M. Co., is down 1000 feet; power supplied by compressors at Potosi shaft.—Santa Eulalia M. Co., owned by the Hearst estate; shaft No. 1 is down 1500 feet, double steam hoist, 150 H. P.; shaft No. 2 is down 500 feet, single steam hoist, 150 H. P.; shaft No. 3 is down 1416 feet, double steam hoist, 150 H. P., Mr. Everlith, manager.—Chihuahua M. Co. (Potosi, etc.) main shaft is down 1500 feet; double steam hoist; 500 H. P. shaft; No. 2 is down 800 feet; power supplied from main shaft by compressed air; manager, S. J. Sullivan.—Kansas City M. Co., Guggenheim Trust, American S. & R. Co., main shaft is down 1500 feet; 250 H. P. steam plant; manager, J. Mitchell.—Santo Domingo M. Co. (same as Chihuahua M. Co.) shaft is down 1750 feet; 250 H. P. steam plant; manager, S. J. Sullivan.—Santa Eulalia Exp. Co. is opening Buena Tierra shaft down 1000 feet by raising and sinking; now raising ore through K. C. M. Co. shaft; 100 H. P. steam engine; manager, Dr. Jackson.—The Baltimore shaft is down 1300 feet, with levels east from 1000, 1100 and 1200 feet of 200 feet each; 44 H. P. gasoline hoist; not running at present.—The Bustillos shaft is down 600 feet; 50 H. P. steam hoist; manager, J. P. Hutchinson.—San Juan, Holmes manager; one 15 H. P. plant underground on the 200-foot level, a 25 H. P. engine and plant on top; both steam engines.—El Cristo shaft cuts vein at 100 meters; 22 H. P. gasoline engine; manager and owner, L. Seijas.—The Juarez shaft cuts vein at 97 meters; 12 H. P. gasoline engine; manager, J. Gasson.—La Vergara has 22 H. P. gasoline engine; shaft down 600 feet; owner, L. Seijas.—Las Mercedes shaft is down 320 feet; 25 H. P. gasoline engine; manager, T. Sullivan; owned by the Chihuahua M. Co.—Santa Juliana No. 1 shaft is down 600 feet; 22 H. P. gasoline hoist; shaft No. 2 is down 200 feet; 12 H. P. gasoline hoist; manager, Mr. Everlith.—Nueva Santa Eulalia is owned by the Santa Eulalia Exp. Co.; shaft is down 200 feet; 22 H. P. gasoline hoist; manager, Dr. Jackson.—Iheria No. 1 has 22 H. P. gasoline engine; shaft down 200 feet; owned by Ryan & Dudley.—The San Antonio has 44 H. P. gasoline hoist; shaft down 600 feet; tunnel taps vein at 600 feet, coming from El Colon to the north; concentrating plant site and water for the same developed 1 mile northwest of main shaft.

The Lucky Joe M. Co. has made a rich strike on its property near Bachiniha, 30 miles south of Chihuahua. J. E. Case is one of the owners.

#### Jalisco.

The Las Bolas silver mine in the Cuale district has been purchased by H. L. Chlostry of Guadalajara for himself and associates for \$60,000.—H. Sahlayrolles of Zapotlan reports a discovery on the Contla hacienda, Tamazula. He is driving a new tunnel.

#### Sonora.

El Porvenir mine, 6 miles southwest of Cananea, is being worked under the direction of P. J. Tehaney.

### SOUTH AFRICA.

There were 34,350 Chinese working the mines of the Rand on April 1, 1905.

## Personal.

P. H. EDLESSEN has charge Monumental mine, near Granite, Or.

J. H. MYERS has returned to Denver, Colo., from Chicago, Ill.

W. T. NASSAUER is manager Whitman M. Co. at Pearl, Idaho.

T. P. LAMB is superintendent New Jersey mine, at Chlorido, Ariz.

J. C. GREENWAY is superintendent Oliver Iron M. Co. at Bovey, Minn.

C. S. GALLOWAY has charge of work on the Fremont at Providence, B. C.

J. W. RIGGLE is superintendent Black Butte Extension mine, Goldfield, Nev.

C. WILSON is superintendent Roosevelt group near Vivan, Mohave Co., Ariz.

G. OSWELL has been appointed superintendent Midway mine, near Sumpter, Or.

E. STALKNECHT is superintendent Gibosa mine near Jimenez, Chihuahua, Mexico.

C. A. HEBERLEIN is manager Alma M. & M. Co. at Zacatecas, Zacatecas, Mexico.

JOHN LIDDELL, superintendent Gleeson mine, at Iowa Hill, has gone to Sierra City, Cal.

C. M. COLLINS is superintendent Arps Bros.' group, Red Mountain, near Ouray, Colo.

E. H. BACKUS, an owner of the Columbia mine at Bourne, Or., has been at the mine.

M. LINDLEY is manager Shasta May Blossom mine, near Winthrop, Shasta county, Cal.

W. PARISOT, manager Atlas mine at Buffalo Hump, Idaho, has been at Spokane, Wash.

W. ROBINSON has been appointed superintendent Silver Shield mine at Bingham, Utah.

J. H. ENGLISH has been elected superintendent Spanish Ridge mine, near Washington, Cal.

B. F. PETERS has charge Juanita and Bonnie Belle group, 16 miles southeast of Prescott, Ariz.

H. A. MEGRAW of Baltimore, Md., has been appointed manager Montgomery M. Co., Candor, N. C.

THEO. VAN WAGENEN arrived in London, en route to California, from South Africa on the 8th inst.

J. M. DAY of San Francisco, Cal., has been at his mines at Gold Road and Vivan, Mohave Co., Ariz.

L. W. TRUMBULL has been appointed consulting engineer Strong Copper Co. of Laramie and Leslie, Wyo.

J. A. FULTON has been appointed assistant manager Sky Blue M. Co. in the East Rand district, South Africa.

HARRY LA MONTAINE, manager Sultan M. Co., near Hillside, Ariz., has returned to the mine from a trip East.

N. C. BONNEVIE has returned to Denver, Colo., from a trip through Idaho and Washington on professional business.

E. GRAHAM of the Southern M. M. & D. Co. at Silver Plume, Colo., is in Nashville, Tenn., on two months' business.

PRESIDENT S. L. BUTLER, Pioneer Sampling Co., has appointed C. D. Rookledge as general manager at Salt Lake City, Utah.

E. J. BONESTELL and E. C. HUNDLEY, Sutter Creek, Cal., have been appointed shift bosses at the Darien mine, Darien, Panama.

J. M. BLYTHE, secretary F. M. Davis Iron Works Co., is in Los Angeles and other California points on business connected with his firm.

CLARENCE LAWSON, the manager of the J. Geo. Leyner Engineering Co. of Denver, Colo., is in San Francisco, Cal., with his family.

PRATT, VANDEMOER & WARBURTON, mining, mechanical and civil engineers, have opened an office at 522 McPhee Building, Denver, Colo.

W. W. NORTON, superintendent East Helena, Mont., smelter, has been appointed superintendent Murray smelter at Salt Lake City, Utah.

W. J. KEOUGH, formerly superintendent Red Boy mine, near Granite, Or., has been appointed superintendent Minerva M. Co., Atlanta, Idaho.

C. H. MCMAHAN has resigned as superintendent Montezuma Lead Co. of Santa Barbara, Chihuahua, Mex., to devote his time to private interests and engineering practice in El Paso, Texas.

E. B. MILLER has resigned as superintendent Spanish Ridge mine, near Nevada City, Cal., to take the superintendency Mountain View mine, near Washington, Cal. He is succeeded by J. H. English.

LAST WEEK it was erroneously stated that Alfred von der Ropp had resigned the superintendency of the Selby Smelting & Lead Co.'s works at Vallejo Junction, Cal. The MINING AND SCIENTIFIC PRESS is pleased to state that such is not the case.

H. C. BELLINGER, who retired from the superintendency Yampa smelter in Bingham Canyon, Utah, has gone to Spokane, Wash., where it is reported he will enter the service American Smelting & Refining Co., by which his skill has been long sought.

THE following officers have been re-elected by the Colorado Mine Operators' Association: President, F. J.

Campbell of the Vindicator Con. M. Co., Cripple Creek; secretary, W. E. Pasmore, Denver; executive committee, E. A. Colburn of the Ajax M. Co., Cripple Creek; R. L. Martin of the Gregory-Buel Con. M. Co., Central City; T. W. Beam of the Japan M. Co., Telluride.

## Books Received.

"Origin of Certain Place Names in the United States," by H. Gannett, Bulletin 258 of the United States Geological Survey.

The United States Geological Survey has issued "Forest Conditions in the Gila River Forest Reserve, New Mexico," by T. F. Rixon; "Lignite of North Dakota and its Relation to Irrigation," by F. A. Wilder, and the Fayetteville Folio of Arkansas and Missouri.

The Department of Geology of the University of California in its fourth volume has issued "The Geology of the Upper Region of the Main Walker River, Nevada," by D. T. Smith; "A Primitive Ichthyosaurian Limb from the Middle Triassic of Nevada," by J. C. Merriam; "Geological Section of the Coast Ranges North of the Bay of San Francisco," by V. C. Osmond; "Arcas of the California Neocene," by V. C. Osmond, and "Contributions to the Paleontology of the Martinez Group," by C. E. Weaver.

The effect of the popular demand on book production is well exemplified in the recent additions to the literature on cement and concrete, a number of which have been reviewed recently in these columns. The latest received is "Cement and Concrete," by L. C. Sabin. This differs from most of the preceding treatises in giving the results of much original research. It is essentially a book for the user, and not for the manufacturer, of cement. In fact, as compared with recent practice of manufacture on the Pacific coast, the methods described seem sadly out of date. The treatment on physical tests is exceedingly good, giving also much material on the results of tests. The tables of actual quantities required in making up different mortars are complete for some special cement, but will probably have to be modified by a constant for other makes. The lack of illustrations is noticeable. On the whole, the book is comprehensive and apparently accurate. It lacks a few details on costs and practical work, which probably can best be supplied from the reader's own experience. It is published by the McGraw Publishing Co., 114 Liberty street, New York City, for \$5, and will be sent postpaid by the MINING AND SCIENTIFIC PRESS upon receipt of cost.

## Commercial Paragraphs.

R. D. SEYMOUR, manager Denver, Colo., branch The Trenton Iron Co., reports the removal of his office from 1711 Tremont street to 237 Equitable building, Denver.

STROMBERG-CARLSON TEL. MFG. CO. report that they have recently received an order for mine telephones from the Jupiter G. M. Co., Germistown, Transvaal, South Africa. Some of these telephones are to be worked in shafts 4300 feet in depth.

A. E. LINDROOTH, SHUBART & CO., Denver, agents for the Goodman Manufacturing Co., have closed contracts with the Colorado Fuel & Iron Co. for the installation of the Morgan system of third rail haulage at the Fremont mine. This is to operate on the main haul with a grade of 5½% against the loads. The Link-Belt Machinery Co. of Chicago, through their agents, A. E. Lindrooth, Shubart & Co., are building shaking screens and tippie equipment for the Colorado Fuel & Iron Co.'s Coal Creek mine. The Raton Coal & Coke Co. have started their new washery at Gardner, N. M. Designs were made by A. E. Lindrooth, Shubart & Co. of Denver, who also equipped the plant. The conveying machinery was furnished by the Link-Belt Machinery Co., the jigs by the American Concentrator Co., and the engine by the Goodman Manufacturing Co. The Dawson Fuel Co. has recently adopted the New Century jig for coal washing. The order was placed with A. E. Lindrooth, Shubart & Co. of Denver, who are Western agents for the American Concentrator Co.

THE C. O. Bartlett & Snow Co. of Cleveland, Ohio, under date of April 13th, write: "We met with a severe loss by fire on the 11th of April. The fire broke out about 12:30 A. M. and almost immediately spread throughout the main buildings. Thirteen fire engines and two fire boats responded to the call. Our main buildings were badly damaged. The office buildings were not much damaged and our boiler and engine were not badly injured. Our greatest loss was in patterns. The largest part of our machinery was not seriously injured. We have immediately commenced to get our buildings in shape and expect to start up in the machine shop department next week and in our boiler shop within two weeks. The Ohio Ceramic Co., the McMyler Mfg. Co., the Bowler Foundry Co. and the Cleveland Gas Light & Coke Co. and others have kindly offered us the free use of some of their tools; therefore we will be able to complete our contracts and fill our orders with little delay. We ask that our patrons and friends be a little patient with us, assuring them that the delay will not be long. We can fill small orders from stock which was not damaged."

THE Fred. M. Prescott Steam Pump Co., Milwaukee, Wis., report orders from the Pewabic Co., Iron Mountain, Mich., one triple-expansion mine pumping engine, capacity 1500 gallons per minute against a vertical head of 1000 feet; from the Copper Queen Con. M. Co., Bisbee, Ariz., one compound and condensing mine pumping engine, capacity 600 gallons per minute against 1250-foot head; from the American Smelting & Refining Co., Omaha, Neb., one duplex pot-form converter pump,

capacity 250 gallons per minute against a pressure of 500 pounds per square inch; from the Calumet & Pittsburg M. Co., Bisbee, Ariz., one independent air pump and condenser, capacity 20,000 pounds steam per hour; from the Union Electric Light & Power Co., St. Louis, Mo., two horizontal, duplex pot-form boiler-feed pumps, each with a capacity for feeding 30,000 H. P. of boilers. The Prescott Steam Pump Co. state that these are the largest pumps of this type which have been built or installed in any electric light or railway power plant in the United States. They also report an order from the Milwaukee Light, Heat & Traction Co., Racine, Wis., for one independent air pump and condenser with a maximum capacity of 20,000 pounds steam per hour.

## Latest Market Reports.

SAN FRANCISCO, April 21, 1905.

### METALS

SILVER.—Per oz., Troy: London, 26½d (standard ounce, 925 fine); New York, 64c; bar silver, 56½c, refined (1000 fine); San Francisco, 56½c; Mexican dollars, 46c, San Francisco; 4½c, New York.

COPPER.—New York: Standard, \$15.25; Lake, 1 to 3 casks, \$15.25@15.25; Electrolytic, 1 to 3 casks, \$15.75; Casting, 1 to 3 casks, \$15.00. San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18@24c. London: £66 17s spot per ton.

LEAD.—New York, \$4.60; Salt Lake City, \$3.50; St. Louis, \$4.12½; San Francisco, \$3.70, carload lots; 4½c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5½c; pig, \$4.85. London: £12 10s 6d per long ton.

SPELTER.—New York, \$6.00; St. Louis, \$6.15; London, £24 ½ ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

TIN.—New York, pig, \$30.40@30.60; San Francisco, ton lots, 32c; 500 lbs., 31½c; 200 lbs., 32c; less, 33c; bar tin, 34½c, 35@37½c. London, £135 10s.

PLATINUM.—San Francisco, crude, \$18.50 per oz.; New York, ingot, \$19.50 per Troy oz. Platinum ware, 75@82c per gram.

QUICKSILVER.—New York, \$40.00@41.00, large lots; London, £7 12s 6d; San Francisco, local, \$38.00 per flask of 75 lbs.; Denver, \$45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 20c; San Francisco, Plumbers', 100-lb. lots, 16.75c.

ZINC.—Metallic, chemically pure, 7½ lb., 50c; dust, 7½ lb., 10c; sulphate, 7½ lb., .04c.

NICKEL.—New York, 55@60c per lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c per lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

### STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$16.35@16.85; gray forge, \$16.65; San Francisco, bar, 3c per lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, \$23.00@27.00; open hearth billets, \$23.00@27.00; San Francisco, bar, 7c to 12c per lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, 1c per lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, 1c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LIME.—Santa Cruz, \$1.25 country, \$1.25 city per bbl.

CEMENT.—Imported, \$2.15@2.65 per bbl.; California, carload lots, \$1.90 f. o. b. at works; small lots, \$2.20 per bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

### GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 7½c; Hallett's, 7½c; San Francisco, 1000-lb. lots, 9c; 300@500-lb. 9½c; 100-lb. lots, 10½c.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lot, Eastern and foreign: Wallsend, \$7.50; Brymbo, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8.00; Cumberland, \$13.00; Cannel, \$8.50; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13.00 in sacks; Sunnyside, \$8.50, long ton.

POWDER.—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1\*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1\*\*, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg.

CAPS.—3x, \$5.50@6 per 1000; 4x, \$6.50@7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

FUSE.—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c per set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98%-99%, jobbing, 23@24c per lb.; carloads, 23@23½c; in tins, 30c; soda ash, \$2.00 per 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c per lb.; Cal. s. soda, bbls., \$1.10@1.20 per 100 lbs.; sks., 90c@1.00; chlorate of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2½c; powdered sulphur, 2½@2½c; flour sulphur, French, 2½@—c; alum, \$2.00@2.25; California refined, 13@12c; sulphide of iron, 8c per lb.; copper sulphate, 5½@5½c; chloride of lime, spot, \$2.50@2.75; sulphuric acid, in carboys, 66% B, 1¼@2c per lb.; nitric acid, carboys, 8c per lb.

OILS.—Lined, boiled, bbl., 60c; cs., 65c; raw, bbl., 58c; cs., 63c; Lucol oil, boiled, bbl., 51c; cs., 56c; raw-bbl., 49c; cs., 54c. Kerosene—Pearl, per gal., 19c; As;

tral, 19c; Star, 19c; Extra Star, 22c; Eocene, 21c, Elaine, 25c; Water White, in bulk, 12½c; Mineral Seal iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Minera; Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 16c, do., cs., 22½c; 86° Gasoline, bulk, 25c; do., cs., 31c; 83° Naphta or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 63c; Bleached, do., 57c; Whale Oil, cs., 52@57c.

BORAX.—Concentrated, 6@7c ½ lb; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5@6c ½ lb; No. 1, 4@5c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c ½ lb.

MOLYBDENUM.—Best, \$2.75 ½ lb.

CHROMIUM.—90% and over, ½ lb., 80c.

PHOSPHORUS.—American, ½ lb., 70c.

SODIUM.—Metal, ½ lb., 50c.

BISMUTH.—Subnitrate, ½ lb., \$2.10.

URANIUM.—Oxide, ½ lb., \$3.50.

MERCURY.—Bicbloride, ½ lb., 77c.

TUNGSTEN.—Best, ½ lb., \$1.25.

SILVER.—Cbloride, ½ oz., 90c@\$1.00; nitrate, 55c.

RED LEAD.—500 lbs. and over at one purchase, ½ lb., 7c; less than 500 lbs., 7½c.

MANGANESE.—Black oxide, ½ lb., 2½@4c.

MAGNESIUM.—Pure, N. Y., \$1.60.

FIRE BRICK.—Domestic, carloads ½ 1000, f. o. b., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skewback, \$30.00; circle, \$32.00.

FIRE CLAY.—Domestic, ½ ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, \$8.50.

### New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING APRIL 11, 1905.

787,258.—ELEVATOR—F. B. Austin, Tomshstone, Ariz.  
786,948.—BALING PRESS—W. S. Bradshaw, San Jose, Cal.  
786,954.—PICTURE EXHIBITOR—R. Cohen, S. F.  
786,956.—BOX MAKING MACHINE—W. Corkhill, Corona, Cal.  
787,287.—PRESSURE REGULATOR—G. H. Dworzek, S. F.  
787,088.—NUT LOCK—T. B. and M. F. Earhart, Stockton, Cal.  
787,292.—DYNAMO—T. B. Hatch, Los Angeles, Cal.  
787,098.—HAT HOLDER—M. S. Helman, Los Angeles, Cal.  
787,294.—BILGE BLOCK—J. Hickler, Pasadena, Cal.  
786,900.—STOVEPIPE FASTENER—R. H. and W. C. Hodge, Medford, Or.  
786,968.—SPUD GRIP—J. W. Hollenbeck, Rio Vista, Cal.  
786,967.—STAMP STEM GUIDE—F. W. Hooper, Grass Valley, Cal.  
787,045.—OIL BURNER—Kipling & Worden, Los Angeles, Cal.  
787,208.—SADDLETHROW—T. J. Morrish, S. F.  
786,988.—STREET CAR REGISTER—F. Paduvert, S. F.  
786,860.—FENCE POST—H. F. J. Slevierkropp, Hood River, Or.  
786,853.—PUNCHING MACHINE—E. A. Stickney, Sacramento, Cal.  
787,129.—GATE—J. E. Stinton, Monroe, Wash.  
787,237.—UMBRELLA—G. Turner, Tacoma, Wash.  
787,344.—PUMP—D. M. Watson, Portland, Or.  
786,928.—GAS LIGHTER—A. F. Williams, Berkeley, Cal.  
787,018.—PLOW SCRAPER—W. O. Wimer, Portland, Or.

### Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s Scientific Press United States and Foreign Patent Agency, the following are worthy of special mention:

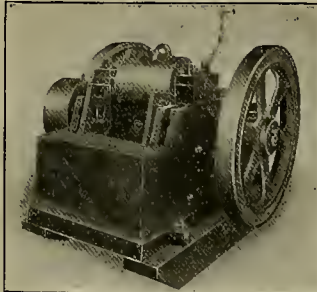

SPUD GRIP FOR DREDGERS, ETC.—No. 786,968. April 11, 1905. J. W. Hollenbeck, Rio Vista, Cal. This invention relates to an improved grip for the spuds of dredgers, pile drivers and the like. The object of the invention is to provide a durable, powerful, practical grip, which will invariably take a firm hold on the spud and will not slip, which will not cut or destroy the spud, and which shall be simple and

can be quickly applied. The device comprises two hinged yokes, a shoe carried by the hinge, a hearing plate opposed to said shoe and supported by one of the members and interposable within the other member when the two are engaged with an object to be gripped, and other necessary details of construction.

STAMP STEM GUIDE.—No. 786,969. April 11, 1905. F. W. Hooper, Grass Valley, Cal. The object of this invention is to provide a comparatively light, simple, easily adjusted metal guide with means for preventing relative longitudinal movement of the sections of the boxes in which the stems slide, the boxes being securely held in the guide without bolts or other independent fastenings. The device comprises a casting having a tapered socket and an opening in one side of the socket for the admission laterally of a stamp stem, and a sectional guide block seating in said socket, the sections of said block having their shutting edges inclined relative to the axis of the bore, and other details of construction adapted to bring about the desired result.

BALING PRESS.—No. 786,948. April 11, 1905. W. S. Bradshaw, San Jose, Cal. The object of this invention is to provide a novel, simple, safe, positive and practical means for opening and closing the door of a haling or hay press. It consists in the combination of a press box, a follower therein, a door for said box, a sweep, a rock shaft, toggles having one member fixed to the shaft and the other pivoted to the door, fast pulleys on said shaft, door closing means including flexible connections between one of said pulleys and devices operated by the sweep, door opening means including flexible direct connections between the other of said pulleys and the follower, and an expansion spring interposed in said door closing flexible connections for the purpose specified.

STREET CAR REGISTER PROTECTOR.—No. 786,988. April 11, 1905. F. Paduvert, San Francisco, Cal. The object of this invention is to provide a protective device which will be operated simultaneously with the registering mechanisms and announce to the eye and ear the actual record if any made by the conductor. It consists in a protective device comprising a casing including two operating levers, two other levers in the path of said operating levers and arranged each to be operated on the oscillation of either of the operating levers, two bells of different tone quality, hammers relative to said bells, means carried by said second levers to operate said hammers, and visible signal mechanism operable by said other levers, said signal mechanism including semaphore arms normally disposed in the path of said other levers, spring detent means to hold either semaphore in exposed position and means for retracting a detained semaphore, and other details of construction.

## Development in New Regions.

Five years ago southern Nevada attracted little attention as a region of great though undeveloped mineral resources. The mines at Good Springs, Searchlight, Johnny and Quartette in southern Lincoln county were known, and some rather desultory work was in progress. Many stories were current of phenomenal finds by the prospectors who crossed the desert in early days, among them being the Breyfogle and Gunsight mines—discoveries reputed to be of fabulous richness, but of indefinite location, as the alleged discoverers were never again able to find the rich veins. The discovery of the Tonopah veins gave the first substantial impetus to the development of that section of the county, and then rapidly followed the discovery of Gold Mountain, Crater, Ray, Lone Mountain, Goldfield, Bullfrog, Lida, Kawitch or Goldreed, and a number of other, but as yet, lesser camps, until to-day southern Nevada is one of the most active mining fields in the world. The discoveries made at Tonopah, Goldfield and Bullfrog lend a color of truth to the stories told by the pioneers who came into California from Utah by way of Death valley in the early days, for none of the reported discoveries of those times can compare with the actual results obtained at the surface of the ground in Goldfield district within the past year. The old stories were of iron-stained quartz in which could be seen free gold running hundreds of dollars per ton, but none of the argonauts told of desert sand nearly half gold, as was found in a few instances at Goldfield, as on the Sandstorm and some other claims, where the fortunate discoverers shoveled up the surface soil, rejecting the roots of the greasewood, which were burned and their ashes added to the pay dirt, and the bedrock swept as clean as a floor to obtain the last grain of the precious gold. These are the kind of strikes that have developed other

Tipple and Washer, Victor Fuel Co., Hastings, Colo. (See Page 266.)

regions, even more unfortunately situated than these camps of southern Nevada. Kalgoorli, Coolgardie and most of the other now noted mining towns and districts of Western Australia were far worse to invade than ever was southern Nevada. Nearly 400 miles from the coast, and almost that far from fresh water, except during the infrequent rains, yet after the discovery of Baley's Reward mine, at Coolgardie, thousands of venturesome prospectors rushed into that desert of bush and sand, and far more men perished from heat, disease, lack of water and exposure than has ever met a similar fate in all of the southwestern part of the United States under similar conditions. A noted miner and prospector made a "trip of discovery" in 1862 for the Government, passed over the Coolgardie field and then wrote a report entitled "The Non-Auriferous

Character of the Rock of Western Australia." In 1869 the Australian Government offered a bonus of \$25,000 to the prospector who would discover a gold mine within 300 miles of the west coast of Australia. In 1873 a number of miners from Ballarat were taken to Western Australia to prospect, and before anything of consequence had been discovered a stamp mill was built in anticipation of the result. The entire enterprise ended in failure. The first discovery of note was made in 1885 at Kimberley and 2000 men rushed into that field, and Southern Cross was discovered in 1887 as a result of the Kimberley find, in much the same manner as the Goldfield discovery was the result of that of Tonopah. Before 1891 several new fields were reported over a widely scattered region. In 1891 Bayley and Ford discovered Coolgardie and in a few days had picked up from the surface of the ground nearly \$15,000. Following this discovery came the greatest rush of those times. Kalgoorli was discovered in 1893.

There is no great difference in the character of events leading to the development of Western Australia and the great basin of the southwestern United States, aside from the bonus offered by the Government. The same idea, the same desire—to quickly accumulate a fortune—has actuated men in both instances, and, in fact, in every instance where there is a stampede to a new mining district. In these strenuous efforts there is much of the element of chance, for it is usually the lucky one who makes the best finds. In the case of Goldfield there are numerous instances of men working diligently on their leases and finding little or nothing, and quitting to try another place, when a rich find is made in a comparatively small area between two of the trenches cut by the former occupant of the lease. It is not exactly a survival of the fittest, for the fittest often fails to "make a hit" with fortune in the strenuous life of a new mining camp, whether in the deserts of Australia, the great basin, in the region of the poles, or in the most favored mining country on earth. Some of the most valuable discoveries have been the result of fortuitous circumstance, unexpected by the fortunate prospector, but they who hope for the smile of Dame Fortune must seek it.

THE engineering difficulties to be overcome in coal and metal mining are numerous and varied in character, but they are not more difficult than those arising in the construction of metropolitan subways, aqueducts and other works of public character which are usually at or near the surface. One does not have to go a thousand feet underground to encounter serious difficulties in rock excavation, and the supporting of tunnel roofs, or to carry on superficial excavation while doing little or no damage to existing surface improvements and obstructing traffic as little as possible, such, for instance, as were encountered in the New York subway, and few mining operations require such skill and daring as that which engineered the tunnel under the Hudson river connecting New York and New Jersey.

AT Broken Hill, New South Wales, during the half year ending November 30 last, the output of the Broken Hill Proprietary Company was about 324,500 tons of ore the cost of mining, transportation, reduction and other charges being £577,322, or about \$8.75 per ton of ore treated, the output in metals consisting of gold, silver, copper, lead and zinc, and as a by-product a considerable amount of sulphuric acid. It is stated to be the intention of this progressive company to enter the market as manufacturers of spelter from its own ores. Until the past year or two these zinc ores in the Barrier field have been a drawback and source of expense, but now, owing to changed conditions, the zinc is yielding a good profit, in the same way that this once despised ore has now become a source of dividends to many American mines.

## Cost of Mining.

Amador county, California, has developed the deepest and most extensive mines on that great mineral belt commonly called the Mother Lode. Nearly all of the mines now working on this lode in Amador county are more than 2000 feet in depth, the Keystone at Amador City being a noted exception, the greatest depth reached there being 1575 feet, though the greatest development is above the 1000-foot level. Where such deep mining prevails and is carried on so extensively as in this district, the figures of cost are of more than usual interest to mining men everywhere. It is realized that the items which go to make up the cost of mining are largely influenced by existing conditions, as well as by the competency of the management. Generally speaking, on the Mother Lode, in Amador, the ore shoots occur in the vicinity of clay, slate and amphibolite schist, both usually being present, though the deposits are not, strictly speaking, contacts. In part they are such, but more often the fissure cuts diagonally across the slates and schists at a low angle, in both strike and dip. Heavy gouges and swelling ground are characteristic features, and these add not a little to mining expense, chiefly in supporting the ground and in renewing timbers. In many respects the mines, from the Bunker Hill on the north to the Argonaut on the south, a distance of nearly 6 miles, have similar characteristics, though with many important differences. In some of the mines the ground is much broken, faulted and disturbed, resulting in heavy ground, and generally adding much to the cost of deadwork. All of these mines, with the exception of the Argonaut, have their original shafts sunk in the fissure, and in this district can be seen an object lesson which teaches that it is economy to sink shafts in the hard country rock rather than on the fissure. The Argonaut shaft is an incline and was sunk largely in the country rock. The Kennedy and Oneida have vertical shafts down about 2700 and 2300 feet respectively, and the Wildman has a vertical shaft down 650 feet which is projected for 4000 feet. These vertical shafts were sunk at a cost approximating \$60 per foot, nearly double the cost of sinking the inclines in the fissure, but it is estimated by the several superintendents that the cost of maintaining these inclines in the heavy fissures is from \$6000 to \$10,000 per annum—no small item in the operation of a low-grade mine. A vertical shaft 2000 feet deep would cost, according to the above figures, \$120,000, and an inclined shaft to the same level—about 2300 feet at 63°—would cost about \$90,000. The surface plant in either case would be about the same. This shows an advantage in first cost of the inclined shaft over the vertical shaft of about \$36,000 to reach a vertical depth of 2000 feet, but at an average cost of maintaining a working shaft in the heavy swelling ground of about \$8000 per year, the real advantage of the vertical shaft in firm, hard ground is at once apparent.

Seldom is one of these deep inclines sunk without suspending sinking to carry on stoping operations from level to level, but where the shaft has been carried down rapidly it is not possible to sink 1500 feet without making more or less repairs to the shaft in that portion first finished near the surface, and as time goes on the entire shaft requires careful and almost constant attention from a repair gang of several men. Not only is such a shaft a source of constant direct expense, but it is the occasion of other expense incidental to operations being retarded by reason of such a shaft. The vertical shafts already sunk have, with few exceptions, cost very little for repairs since they were first sunk. Some of these have been in use now from eight to twelve years, and are still in good condition, costing comparatively little for repairs, and have long since repaid the additional cost of sinking. It is necessary to maintain openings in the vein from the lowest level to the surface in all of these mines, but the placing of the main working shafts in the fissure is a practice which should be discontinued. The Central Eureka mine, near Sutter Creek, is a typical mine of that section, and though in some respects more fortunate than some of its neighbors, it still affords an excellent example of the cost of practical mining operations on the Lode in Amador. In this mine, during the year ending April 1, 1905, about 60,000 tons of ore were raised all from depths

ranging from 1900 feet to 2300 feet through an incline shaft sunk on the fissure. The deadwork and development account during the period covered by the report was but \$22,686, or about 37.5 cents per ton of ore treated. An equal sum covered the cost of milling, the cost of mining being \$1.41 per ton, or a total cost per ton of \$2.175 for all expenses. These charges do not include deterioration of plant, but the showing made is a good one and gives a fair idea of the cost of mining under the conditions existing there.

## Must Use Protected Cages.

The State Legislature of Nevada recently passed a law requiring that any shaft in that State more than 450 feet in depth shall be provided with a cage over which shall be fixed a steel hood, for the protection of the men riding on the cage, and that in all shafts less than 450 feet deep, where bucket and crosshead are in use, a platform must be provided for men to stand upon while being lowered or raised in the shaft, and further, that this platform be placed above the crosshead. The text of the bill is not at hand, but the newspapers of that State agree in reporting the requirements of the bill as above stated. This bit of mining legislation bears the earmarks of being the work of some one who is not well acquainted with practical mining, for it conveys the impression that the choice of a cage or skip is not optional with the management of a mine deeper than 450 feet, and that cages must be used in all such mines. It is often the case in modern practice to use automatically dumping skips in mines for the reason that their employment admits of handling ore and rock at less cost than is usual with cages. Skips in well regulated mines are equipped with steel shields overhead for the protection of the men. Accidents arising from the employment of crossheads are of rare occurrence, and when they do happen, are usually the result of overwinding or some other act on the part of the hoisting engineer, through carelessness or through inability to control engines for the time being. There have been instances where a crosshead has caught on the guides, where the crosshead was too short and has hung suspended there while the bucket continues to descend, and then, suddenly becoming released, has fallen and knocked the men riding on the chine of the bucket into the shaft; but this is also of very infrequent occurrence and may be prevented by the use of proper length and form of guide shoes. The placing of a platform above the crosshead must necessarily contemplate a structure similar to a cage, which, having shoes running in guides, renders a crosshead unnecessary.

It is a common practice to place a bucket beneath a cage for the purpose of sinking, the bucket being from 15 to 20 feet below the platform of the cage, to which it is attached by a short section of cable or a chain. While it is the duty of legislative bodies to protect the citizens of the State in every walk of life, it seems unfortunate that some of these acts are of a character which will not bear common sense investigation.

TALK of anticipated labor troubles comes from the staid old tin mines of Cornwall, where it is stated that the machine men employed show much "indifference" as to the amount of work accomplished, notwithstanding the "inducements" offered by the mine managers. What the inducements referred to were is not stated, but the managers say the time has arrived when the question must be settled whether "the mines shall keep the men working, or the men keep the mines working." The average wages earned by machine men in a noted Cornish tin mine is stated to be about \$37.50 per month, ranging from about \$25 to \$55 per month.

THE law passed by the last California Legislature making it unlawful to misrepresent anything concerning the property of any incorporated mining company in that State has been in force too short a time to make it possible to say what its general effect will be on the organization and promotion of new mining enterprises. If strictly observed, it will have a tendency to make some mining prospectuses rather tame reading, compared with what they have usually been in the past.

## CONCENTRATES.

THE Dominion of Canada during 1904 produced minerals to the value of \$60,000,000. This includes non-metallic as well as metallic products.

THERE are numerous devices for automatically dumping ore buckets and cars. The latter are usually dumped on some form of balanced track section, known as a tipplo.

COPPER in ores usually gives more or less trouble in cyanidation for gold. Particularly is this the case with the oxidized ores such as oxides, carbonates and silicates of copper.

THE standard measure of the value of an electric volt is a voltaic cell, called the Clark cell, the electro motive force of which is 1.434 volts at a temperature of 15° C. (or 59° F).

COARSE FREE GOLD is of common occurrence in mispickel (arsenical pyrites). In some mines the occurrence of this mineral is an indication of the proximity of pockets of gold.

STEAM SHOVELS are extensively used in mining in the open workings of the iron mines of the Minnesota and Lake Superior iron mines, and to a limited extent underground also.

WHEN a shaft is sunk vertically to a vein having a dip, a curve should be put in, the radius of which will admit of running skips on the curve without shock or necessitating a slackening of speed of the skip.

THE cost of mining and milling at a prominent mine on the Rand—the Van Ryn—is stated to be a few cents under \$5 per ton, but this is not an absolute criterion of the cost at other mines in that district.

It is usually much less expensive to break up a boulder with small quantities of dynamite by what is known as bulldozing than to dig boles at one side of the boulder and dumping it into the hole to get rid of it.

THE caving system of mining is not always adaptable to the conditions. Where this system has been employed the geological conditions are peculiarly favorable to it, but it cannot be applied in every case to advantage.

WHEN an ore shoot is being stopped development should be in progress elsewhere in the mine, and waste from this dead work should be used as filling wherever possible, instead of raising it to the surface, as is commonly done.

It is said that the ores of Republic, Wash., can be treated successfully by concentration and cyanidation of the tailings. These ores have proven very refractory to treatment. The statement above made, it is said, is based on laboratory experiments.

A TROMMEL set with a slope of 3 inches to the foot and carrying a lighter load will usually have higher capacity than one set at 1 inch to the foot and carrying a heavy bank of ore. The latter also requires more power and the wear and tear is much greater.

TO HAVE good concrete the materials must be thoroughly mixed both dry and wet, and then when placed in position, in the wall, or elsewhere, it must be tamped carefully or there will be numerous open spaces which weaken the structure. Tamping should be continued until water rises to the surface.

THE magnitude of hydraulic mining operations must be determined by the amount of water and head available for the purpose. The factor of grade for dump is a most important one. If all other conditions were favorable, the work would be handicapped if there was not sufficient fall to carry away the tailings.

IT is stated that at the La Grange hydraulic mine in Trinity county, Cal., from 10,000 to 12,000 cubic yards of gravel are hydraulicked daily. The flume is 6 feet wide, over 1300 feet long, and paved with steel riffles made from 40-pound steel T-rails. Boulders pass down this flume weighing as much as five or six tons.

FOREHEARTHS are used at copper furnaces and are employed to receive the molten matte, or metal, directly from the furnace as fast as formed, and where any difficulties or irregularities may be promptly discovered and remedied. The forehearts in use at the large plants have a capacity of several tons of molten metal.

THE pressure of a blast created by a fan or blower is measured by what is known as a pressure gauge. The gauge is connected with the blast pipe by means of a rubber hose, and the amount of depression of a column of mercury in the gauge registers the pressure of the blast. A somewhat similar gauge is employed in mines to measure the force of air currents.

WHERE square-set timbers are employed sills should

always be laid in order to facilitate connection from the level below. The sills should also be covered with heavy lagging to hold the filling, and tracks should be laid on top of the sills, lagging being dispensed with on the sill floor. For the best economic results, provision must be made for the connecting of levels without the loss of ore.

ALTHOUGH the gravel of river channels is not usually looked upon as a productive soil after washing, many of the large pits excavated by hydraulicking in early days are now covered with a growth of pine, cottonwood and other trees, beside brush. In time, no doubt, soil will accumulate on these lands and the pits become fertile garden spots.

FLAT HOISTING ROPES are made of a number of small ropes laid side by side and sewed together with annealed cast steel wire. These several ropes are alternately right and left-hand twist, and are composed of four strands, having neither hemp nor wire centers. The number of wires in each strand varies, but is usually either seven or nineteen wires. Some mines make their own flat ropes.

A NEW FEATURE has recently been introduced into the tests to which certain materials are subjected—that of impact. It has long been the custom to test for tensile strength, bending and shearing strength, but there has been little attention given to determining the resistance of materials to shock produced by impact. This test is now applied by a machine devised for this purpose. It is done by means of a falling weight, the force of the blow being registered automatically.

IT is not improper to build powder magazines underground, but they should not be made in the mine workings. There are many accidents recorded of explosions of magazines in mine workings. If the magazine is to explode it is far better to have the explosion occur on the surface or in a special magazine built in a superficial excavation. The magazine must be dry, well ventilated and of even temperature at a point at least 20° above the boiling point of dynamite, which is about 45° F.

ORDINARILY carbon and nitrogen do not combine, but if these two elements be highly heated in the presence of a metal, they combine, forming what are known as cyanides. If a current of nitrogen be passed over a highly heated mixture of potassium carbonate and carbon, cyanide of potassium results (KCN, also written KCy). Carbon which contains nitrogen, such as animal charcoal, when ignited with potassium carbonate, reduces the carbonate, forming potassium, in presence of which carbon and nitrogen combine, forming cyanide of potassium.

A MONTEJUS is a chamber filled with compressed air, similar to the receiver of an air compressor, and is employed in forcing slimes into filter presses. A vacuum chamber is the reverse of the montejus, and is used to aid the passage of solution through a filter. Sometimes the vacuum chamber is placed beneath the filter bed. When the charge has been leached sufficiently, the vacuum pump is started and the solution, or as much of it as possible, is drawn through the filter covering the bottom of the leaching tank, the passage of the solution being accelerated by atmospheric pressure.

CONCRETE was used in the Aspen railroad tunnel in Colorado, on the Union Pacific. The greater part of it was supported by timbers, placed 3 feet center to center, but a portion of the ground was very heavy and in this steel supports made from curved steel I-beams were used and the space between and around them filled with concrete, the inner flange being buried behind 7 inches of concrete. The concrete wall was from 2 to 3 feet in thickness. There are often places in mining work where concrete may be used to advantage to stop the flow of water or foul gases as well as to support heavy ground.

MISFIRES are due to many causes, among which are defective fuse, damp exploders, chilled nitro-powder, cut-off holes and failure to properly "spit" the fuse. Defective fuse and cut-off holes are the most common. It is difficult to avoid altogether the missed hole, for the defects in the fuse are not anticipated or known, and the cut-off hole is the frequent result of shooting a number of holes at the same time, though not simultaneously. Dampness of the caps can be guarded against by keeping them in a proper place. Neither fuse nor caps should be kept underground in quantity, as they always suffer deterioration in the mine.

ELECTRICITY is measured by devices known as voltmeters and ammeters. They are provided with a coil of fine wire through which the current, or a proportional part of it, passes. This wire is attached to a needle or pointer which is suspended between the poles of a permanent magnet and is controlled by two spiral springs, which have a tendency to keep the needle at the zero mark. When a current is passed through the coil, an electro-magnetic torque, which is greater or less according to the force of the current passing through the coil, is established, so that coil and needle are caused to turn against the torque of the springs. The arc over which the needle passes is determined by the current passing through the springs. The principle upon which voltmeters and ammeters work is similar, but the resistance of the circuit of the voltmeter must be very high,

as it receives the full pressure of the circuit to be measured. The ammeter receives the full volume of the current and its resistance must be low.

UNDOUBTEDLY gold is distributed throughout the gravels and soils of the Sacramento valley, California, and to a less extent in the San Joaquin valley, but for the most part this gold is so fine and occurs in such small amount as to give no commercial value to the gravels and soils. The dredging area will be confined chiefly to the vicinity of the mouths of ancient rivers which emptied into the valleys, and also to the modern streams. There are large areas of these gravels, much of which have not yet been tested in any manner. Some of these gravels form hills and knolls of considerable extent, and will have to be excavated dry, if at all, and the gravel conveyed to the nearest water available for washing.

THE rate of increase of temperature in underground workings is very irregular, and from the large number of observations made on the Comstock lode of Nevada, the deep workings of the Mother lode of California, the deep levels of the Rand, in South Africa, and those of Bendigo, Australia, the indications are that the temperature is largely influenced by local conditions. The rate of increase varies in different mines, being from 38 feet for each degree as in one of the Bendigo mines (supposed to be due to poor ventilation), to 200 feet and over in numerous American mines. The hottest places in the Comstock mines, which are probably the hottest in the world, are not always at the deepest points reached, but near large flows of hot water.

THE law requires the discovery of mineral-bearing rock in place as a prerequisite to location of a mining claim. Mineral does not always outcrop in plain sight, and the prospector is sometimes obliged to search for it by digging. In this connection Justice Miller decided in *Crossman vs. Pendry* (8 Fed., 693) that "a prospector on the public mineral domain may protect himself \* \* \* while he is searching for mineral. His possession, so held, is good as a possessory title against all the world, except the Government of the United States. But if he stands by and allows others to enter upon his claim and first discover mineral in rock in place, the law gives such first discoverer a title to the mineral so first discovered, against which the mere possession of the surface cannot prevail."

WHEN the term "load" is used in connection with hoisting operations in mines, the total load is usually meant, as distinguished from the net load or amount of ore or rock hoisted. The total load comprises weight of rope, cage or skip, and the material being hoisted—rock, ore or water. In deep mines the weight of rope often is greater than that of all of the balance of the load. A rope, 1½ inch diameter, hoisting from 3000 feet, weighs about 7350 pounds and a 7-inch flat rope, ½ inch thick and 3000 feet in length weighs over 17,000 pounds—so that the weight of rope is an important factor in calculating the size of a hoisting engine required to hoist a given "net load," and particularly in deep shafts. Even when skips are run in balance the initial load is almost as great as when they are run independently, the only important difference being in the weight of the skip.

THE desilverization of base bullion is generally accomplished by what is known as the Parkes' process, which depends for its success upon the fact that when 1% or 2% of zinc is added to molten base bullion the zinc forms an alloy with the silver, which having a lower melting point than lead, crystallizes, and, being lighter, floats on the surface of the metal and is skimmed off, the lead being then refined separately. Another method of desilverizing lead is by what is known as the Pattison process, based on the fact that when silver-bearing lead is allowed to cool nearly to the point of fusion, crystals of lead will separate which are comparatively poor in silver. These are removed and additional bullion added and the process repeated, which results finally in the production of a large amount of lead low in silver and a much smaller amount of lead rich in silver. By continued repetition of the process, a marketable lead is produced, and the various impurities usually present form a scum or dross at the surface of the bath and are skimmed off, thus purifying the lead.

IT is not good business nor good mining to put in a large and expensive hoisting plant to sink a shaft to 2000 feet. Hoisting engines are made which will do this readily and which cost but a few thousand dollars. By installing a plant of this character, the expense of plant and cost of running it are greatly lessened. If a larger plant is necessary, when the shaft is down that depth, it will be time to install one. It will ordinarily require from 400 days to three years to sink 2000 feet, depending on conditions, and the wear and tear on a large engine during this period would be much greater and more expensive than on a small one. Running two skips of 1-ton capacity each, each engine of the pair would have to make 12,500 trips in sinking 2000 feet to handle the rock alone, beside men, timbers, water and other incidental trips, so that it is safe to say that under ordinary conditions the engines must make upwards of 20,000 round trips each in sinking 2000 feet, and this is a heavy tax on a large engine—much heavier, comparatively, than on a small one, when the amount of work accomplished is considered.

## Gold Dredging in Oroville District, Cal.\*

NUMBER III—CONCLUDED.

Written by L. J. HOHL.

Another set of figures follows covering the operations of dredgers over a period of three years, and it is but fair to state that the high percentage shown under the head of power troubles is not attributable to the present company operating in the field, but to an older electric power plant.

## CAUSES OF STOPPAGES IN PER CENT.

Moving ahead .....	5.7%
Power troubles .....	15.6%
Repairs and holidays .....	75.4%
Sand pump .....	3.8%
Total .....	100.0%

The average running time for the period given was 16 hours, 56 minutes. From other records extending over long periods of time it is probable that the best average running time of the boats will hardly exceed 18 hours out of 24, taking all causes of stoppages into consideration and figuring on 365 days per year. It is true that in a very few cases better running time has been obtained, but where this has been the case it was due to conditions surrounding that case, which it is not safe to figure on in every instance.

While the figures so far presented were for Bucyrus boats, I have condensed from Mr. Monroe's paper in the MINING AND SCIENTIFIC PRESS of February 6, 1904, corresponding data for a 5-cubic-foot Risdou boat, which I give below:

## CAUSES OF STOPPAGES.

Bucket line and ladder .....	30.7%
Clean ups .....	7.7%
General repairs .....	17.9%
Lines .....	9.9%
Power troubles .....	7.9%
Pumps .....	5.4%
Screens .....	4.5%
Stacker .....	9.4%
Total .....	100.0%

The data above extend over a period of one year, but not a picked one, it being a regular calendar year. The bucket line on the boat was renewed during the year, which makes the percentage of time lost on account of the bucket line and ladder high. Comparing the percentage of time lost on account of shaking screens and stacker with the percentage given for the picked year of the Bucyrus boat, we find, curiously enough, that the loss due to the shaking device in either case was exactly the same, while the Risdou stacker shows 9.4% as against 5.9% for the belt conveyor. The running time of the Risdou

As to the capacity of the different types and styles of boats, no fixed rule can be laid down, for the reason that the same dredger in different ground may not be able to make as much of a yardage, owing to local conditions. To mention one of these conditions, I would say that the washing of very sandy soil is more difficult than that of pure gravel, and it may be necessary to cut down the digging, for the reason

that the above figures come pretty close to the capacity.

The cost of production depends to a great extent on the magnitude of the enterprise, which reduces the general expenses, by dividing them up among a number of different boats and by the chance of keeping the repair cost down by the erection of repair shops at suitable locations. It has to be kept in

Dredging in the Boise Basin, Idaho.

that with full buckets the riffles become crowded.

A fair average of yardage would be about as follows: Three-cubic-foot Risdou boat, 25,000 to 35,000 per month; 5-cubic-foot Risdou boat, 35,000 to 45,000 per month; 3-cubic-foot Bucyrus boat, 35,000 to 45,000 per month; 5-cubic-foot Bucyrus boat, 50,000 to 65,000 per month.

mind that the operating expenses are further influenced by local conditions, such as nature of the ground, general efficiency of digging and washing appliances, adjustment of motors and resistances to their work, extraordinary repairs occurring in short periods of time and a number of other details.

The following statement will give a fair representa-

A Modern California Gold Dredger.

dredger for the year amounts to 16 hours, 39 minutes out of 24 hours. The cost of repairs to the conveyor during the year for the Risdou boat amounted to \$1241.28, an amount which about equals the cost of the belt conveyor in this particular instance, if the difference in lost time is taken into consideration.

The above figures would represent the work of a boat, as now in use in the Oroville district, extending over a long period of time.

The maximum obtainable will far exceed the figures shown and may be kept up for a short period with any one of the boats, but for periods of a year and over it will be found from the records of companies who take care to measure their ground accurately

tion of the extremes of the cost per cubic yard of material:

OPERATING EXPENSES IN CENTS PER CUBIC YARD.					
Power .....	1.06	1.20	1.15	1.61	1.77
Repairs .....	2.86	3.03	3.46	2.97	3.80
Labor .....	1.64	1.82	1.85	2.33	2.05
General expenses .....	0.64	0.67	1.23	1.28	0.73
Total .....	6.20	6.72	7.69	8.19	8.35

\* Abstract Trans. Cal. Min. Assn.

The data for the above statement were obtained from different operators in the district; the period over which they extend is in each case not less than one year and in one case more. In some of the figures given the taxes are included under the heading of general expenses, in others they are not. The cost of superintendence in some instances is included under the item of dredger labor, in others it is charged to general expense, but in all cases the totals give all the expenses incident to the working of the dredger and keeping it in good running order.

The life of a boat has not been determined as yet, but with a well and strongly constructed hull which is taken good care of, it should not be less than 12 to 15 years in this climate. It is self-evident that during that period a great portion of the machinery and appliances will have to be renewed over and over again, such as tumblers, ladder rollers, buckets, shaking screens, pulleys and shafts, spuds, conveyors, etc., but the item of dredger repairs, as shown in the above statements of cost of operating, will cover these items and there is no doubt but what the expense

- Sixth—Proximity of water.
- Seventh—Good long working season.
- Eighth—Proper contour of ground.
- Ninth—Accessibility.
- Tenth—Reasonable first cost of land.

The first of these conditions is, of course, influenced by all the rest of them, but practically all these conditions were met with at one time in the Oroville district; at present, however, land with all the earmarks of excellence is not easy to find, and the limit of dredgeable area in the district is being rapidly reached. Other fields, however, will no doubt be found, and with the knowledge acquired in and near Oroville, dredging, while still in the experimental stage, is bound to become a science and take rank with older methods of mining that have been developed to a high grade of perfection.

Gold dredging is even now entering through the portals of discussion and comparison of ideas and experiences, the fields of fixed forms and enlightened knowledge, and if this effort of mine has done a little towards the opening of the portals my object shall

munity from this form of mine accident is accredited to these warnings. In this country no official colliery warnings are given, and even the statistics are lacking to indicate whether there is any relation between the barometer and explosions in America. It is a field in which some profitable work might be done by the government at slight expense.

### The Coal Industry in Colorado.\*

[FROM A STAFF CORRESPONDENT.]

The coal industry is carried on extensively in several counties in Colorado. Among the large producers are Las Animas and Huerfano counties, in the southern part of the State. The coal field in the two counties mentioned is what is known as the southern field, and is believed to be an extension of the Raton district, extending to the south as far as Raton, N. M., and to the north through Las Animas county into Huerfano county to Walsenburg.

Las Animas county produces more coal than any other county in the State of Colorado. The output in this county is controlled largely by the Colorado Fuel & Iron Co., Victor Fuel Co. and a number of smaller companies. The Colorado Fuel & Iron Co. is operating at Tercio, the terminus of the Colorado & Wyoming Railway, running out of Trinidad, Colo., and which is controlled by the C. F. & I. Co., and also along the line of this road at Sopris, Segundo and Primero.

At Segundo, 16 miles from Trinidad, this company has 800 coking ovens. The product from the mines at Prunero, 3 miles distant, is washed and made into coke at this plant. A large percentage of the coal near Trinidad is good coking coal.

At Sopris, the Valley Fuel Co. has recently started operations. This property lies about 6 miles west from Trinidad. The company has a shaft down 75 feet. The head frame is 84 feet from the surface to the wheel. The coal is hoisted to the surface in cars which hold 3500 pounds. These cars are hoisted on self-dumping cages. When the cage reaches a certain point the coal is dumped into a sheet-steel hopper.

The hopper is attached to a pair of Fairbanks automatic scales, where each car of coal is weighed, and from this hopper it passes onto a shaking screen. It passes over 4-inch and 1-inch screens, and from there goes to the loading bins or cars.

The mine has a daily capacity of 260 tons. The vein is 5½ feet thick and opened up about 600 feet from the shaft. The fan supplying air to the mine is placed over another shaft, which is approximately 260 feet from the boiler room. This fan is 16 feet in diameter by 5 feet 2 inches wide. It is used to draw the foul air from the mine or force good air into the mine. It is capable of supplying 75,000 cubic feet of air at sixty revolutions per minute. A small engine, located near the fan, furnishes the power for operating it. This mine is also on the line of the Colorado & Southern Railway and the Colorado & Wyoming Railway.

Mine No. 21, at Starkville, on the main line of the Santa Fe Railroad, is operated by the C. F. & I. Co. The drift on this mine is approximately 4½ miles. The coal is brought to the mouth of the drift by motors and from there hauled by small engines to the tippie, where it is put through the washer and sent to the ovens to be made into coke. Three fans supply air to this mine. The first one is 7x20 feet, and the force fan is 7x12 feet. The intermediate fan inside of the mine is 7 feet. This fan has recently been installed and is known as the Sine. The fans are operated by electricity. At this plant they have 200 coke ovens in operation. The mine produces about 32,000 tons per month. The washery has a capacity of 600 tons per day. The machinery used in the washery is complicated, but works in somewhat the same manner as jigs. The coal passes through the jigs and is carried out with the water and through a revolving screen. As it leaves the trommel it goes into a disintegrator and from the disintegrator to an elevator, where it is carried to the "larry" bin and from there is conveyed to the coke ovens. The coal is handled in such a manner that it is thoroughly dried before reaching the ovens. The ovens are circular in form and lined with firebrick. The retaining walls are made of stone.

An oven is allowed to burn about forty-eight hours. At the expiration of this time the coke is wet down by means of a hose with sprinkler attached. It requires 500 to 600 gallons of water to cool an oven and takes fifteen to twenty minutes to water an oven. The doors are lined with one thickness of brick and luted on with mud and ashes. As soon as the oven is empty it is recharged with about five tons of coal. The ovens are still hot when refilled, and as soon as the door is plastered up they recuperate themselves.

At Grey Creek the Victor Fuel Co. is operating. The product is brought from the mines to the main line of the railroads over their own track, a distance of 10 miles.

The accompanying illustration shows the washer, power house and boiler room of the Victor Fuel Co. at Hastings, Colo.

The slope on this property is 4000 feet deep. The

\*See illustration front page.

The Bucket Line of a Modern Dredger.

rience gained so far, and which will be gained in the future, will have a tendency to gradually diminish such expenses, and what is even more important, forestall the occurrence of larger mishaps.

The prospecting for gold in our district is universally accomplished by means of Keystone drillers. This machine drills a hole of about 7½ inches diameter, the casing for the hole is driven ahead of the drill as far as possible and the drill is supposed to cut out the core, the contents of which are determined by the diameter of the casing, and these contents are brought up by the sand pump, rocked and panned by the usual methods, and from the results the value per cubic yard of the particular hole is determined.

There are no very reliable data on a large enough scale to determine the relative value of the ground as obtained by drill prospects and afterwards developed by the dredger. It seems to be conceded that the percentage to which the dredger will work, provided the drill holes are numerous enough, vary between 70% and 90%. The principal features of a good gold dredging property are:

- First—Paying values in the ground.
- Second—Good bedrock, which can be cut into and scraped up by the digging buckets.
- Third—Depth not exceeding, say, 60 feet below the water line.
- Fourth—Easy digging ground.
- Fifth—Good facilities for power.

have been accomplished.

In conclusion, I want to thank my brother mud-diggers in the Oroville district for valuable information received from them and assistance rendered.

### The Barometer and Coal Mine Explosions.

The comparative infrequency of explosions in English coal mines as compared with those in American mines is noted by the Record Herald of Chicago, Ill., which says 600 lives were lost last year, and insists that one reason that reduces the number in England is the reliance that mine engineers place on the "colliery warnings," with reference to atmospheric pressure, which warnings they have been furnished for the past twenty-four years. These warnings have been based on the theory that explosions are more apt to occur at the time of a sudden fall in the barometer. A fall of 1 inch in the barometer is equal to a reduction of air pressure to the extent of about half a pound to the square inch. With this lessened pressure the gases from the coal issue into the workings of the mine and the danger of explosions becomes suddenly increased, so that extra attention is given to ventilation as a preventive. Warnings are given when the barometer is high and apt to fall suddenly in order that the danger may not be overlooked, and the comparative im-

coal is first hoisted 3000 feet by means of a steam engine and the other 1000 feet with an electric hoist. The coal is then trammed with an endless rope from the mouth of the slope to the tippie, a distance of 300 feet.

The slack is used for coking purposes. The lump coal is not put through the washer, but is shipped for commercial purposes. The production is from 1500 to 1600 tons per day. They have 189 coke ovens. The coal for the ovens is washed through six jigs. Here ninety-five ovens are pulled each day. The plant is equipped with machine shop, hoisting engine, generators and boilers. D. E. Davis is superintendent. This company is also operating at Delongha, a few miles above Hastings, where they have eighty ovens in operation and making preparations to add eighty new ovens. The ovens are recharged at these plants by an electric "larry" car. Each one of these cars will hold five tons of coal. The camps are connected with the main line of the railroad by their own track, which consists of about 12 miles.

The Northern Coal & Coke Co. has considerable property at Aguilar, but has not been operating to any extent since the fire several months ago, which destroyed their mine buildings.

## The Strength and Life of Mine Timbers.\*

NUMBER III.—CONCLUDED.

Written by W. H. STORMS.

E. Hampton, superintendent of the Oneida mine, Amador county, Cal., and who has had much experience elsewhere, has kindly contributed the following:

"The timbers used at the Oneida are yellow, bull and sugar pine, spruce, fir and cedar (native timbers, 50% of which is bull pine) and also some Oregon pine. There are only a few places in the mine that timber of any kind or dimensions has a chance for a natural life—that is, to stand long enough to slowly decay, the ground being very heavy, as nothing is left to tell the tale, but where conditions exist to determine the life of a timber I find that bull pine timbers, 20 inches in diameter, put in place in a well ventilated, dry drift four years ago, are now rotten clear through, without any perceptible fungous growth; that timbers will decay in the Oneida as readily in still air as in a current of air; that fungus will take hold of green as well as dry timbers; that green timbers will better resist fungous growth, and last longer, than dry timbers; that moisture in plenty, where pressure does not exist, continues the life of tim-

ber indefinitely, regardless of ventilation, especially spruce. We cleaned out an old drift in 1903 that was run in the '70s, and timbered with spruce, and found those that were not broken as solid as when first cut.

"For all around mining purposes I consider best: First, spruce; second, yellow pine; third, bull pine, and, in order, sugar pine, fir and cedar. In heavy ground there is but little use for the last three, but I believe cedar will resist decay longer than any other timber. Redwood I know nothing about.

"In February of 1896 the Oneida shaft was started and timbered with 12x12-inch Oregon pine. In July of this year (1904) it had to be retimbered from the collar to 50 feet below. Timbers were all rotten. Change of season and change of atmosphere must be the cause, as gases from the mine never get to the timber, the draft being a down cast. Seventy-five feet below the collar of the shaft, where moisture is a fixed quantity, there is no sign of decay. Oregon timber is a good all around timber, but not equal to California spruce. With pressure it splits too easily. Perhaps if the dealers in Oregon would send to the mines the same quality as they send to the University for testing purposes we might change our opinion."

Frank F. Weber, assistant superintendent of the New Almaden quicksilver mines, Santa Clara county, Cal., has kindly volunteered some valuable information from that section:

"During the last few years the timber used in our main stopes and gangways has been Oregon pine, although in the early history of the mine redwood timbers, either hewn or sawed, were universally employed, and the old workings remaining accessible offer good opportunities for observing the efficiency of this class of timber under various conditions.

"At the time of going into the mine the Oregon timber has been cut probably not longer than three or four months, so that, while it can hardly be classed as well seasoned, it is not as green as that used in some localities where timber, abundant in the vicinity, is cut, framed and ready for use almost immediately.

"Generally speaking, I believe that the condition most unfavorable to the life of any mine timber is one combining warmth with an abundance of moisture. In stopes where this condition is met with the effect on pine as observed here is rapid decay, the timber being attacked by fungus, occasionally, as early as from four to six months. Redwood under the same conditions does not seem to be attacked so readily by the fungus, and its life is considerably longer.

"In making a comparison of the relative enduring qualities of redwood and pine under favorable conditions—in an unusually cold and damp tunnel—the following facts were observed: Ten by ten-inch redwood timbers put in place over thirty-five years ago, while being sound at the center of the stick, showed a decided softening near the surface, although they are still serving their purpose satisfactorily.

"In the stopes requiring considerable timber to support the ground Oregon pine (Douglas spruce) has been employed, and is found to be the most satisfactory in every way. Especially is this true where the square set system is employed, for in taking

Framing of Shaft Set Viewed from the Side.

Placing a Cap on a Drift Set, Hayden Hill Mine, Cal.

Square Sets with Round Timbers, New Almaden Mine, Cal.

At Walsenburg the C. F. & I. Co. is operating the Walsen and Robinson mines. Considerable work is being done at Pictou, Sunnyside, Toltec and other points near Walsenburg.

## Electrolysis of Platinum.

Platinum is generally considered to be an ideal electrode for electrolytic processes in which the electrodes play no part, says the Electrical Review. It is a good conductor, it does not oxidize, and is generally thought to be unaffected by electrolysis. This is true so long as the current flowing from the electrode does not vary, but, if it vary, electrolysis may take place, although ordinarily there would be no reaction between the conducting solution and the metal. This phenomenon has been investigated recently by Messrs. A. Brochet and J. Tiet, the electrolyte in this case being sulphuric acid. The action took place whether an alternating current or a varying direct current was used. No explanation of this peculiar action is offered. It has been known for some time that metals could be dissolved electrolytically by means of an alternating current, the explanation offered being that, while the greater part of the metal dissolved during one-half of the wave was redeposited during the next half wave, some managed to get out of the reach of the electrode, as it were, and remained in solution; but the action of platinum is not similar to this, for platinum itself is not dissolved by a direct current, but dissolves only when the current varies.

weight this class of timber will stand a surprising amount of buckling and twisting before absolute failure. Redwood, on the other hand, will not support weight nearly as well. It is brittle, and will split and give way without warning—sometimes so quickly that timely repairs are often prevented—while pine shows at which place repairs are needed, and allows ample time in which to do such work.

"With regard to the effect of carbon dioxide gas on timber, I do not believe that it has any noticeable effect one way or the other. It is met with in considerable quantities in portions of this mine, and any particular effect would be noticed. On the other hand, foul gases arising from a pile of decaying timber will, in all probability, cause a favorable condition for like decay in adjacent timbers.

"It would be a hard matter to give an accurate estimate as to how long a stick of timber, such as you mention, would endure even under favorable conditions. However, I should judge that seasoned redwood, in a wet shaft or drift, such as the one heretofore mentioned, and coming in contact with a current of fresh air, should last for all practical purposes from thirty to forty years; Oregon pine, under like conditions, for from fifteen to twenty-five years.

"In my opinion, the best timber for all around mining work is well seasoned pine of the better varieties found throughout the Northwest. As a rule, it is a strong, safe timber to work with, and its life is sufficiently long for all practical purposes. Wherever possible, the class of timber employed should be that

\*Abstract Trans. Cal. Min. Assn.

which best suits the conditions met with, and an ideal state of affairs would be to use redwood in all shafts and main gangways, and timber the stopes and drifts of lesser importance with pine. The price of redwood, which in this locality is nearly twice that of pine, often prohibits its use."

From the notes of Mr. Weber it will be noticed that comparison is made only with Oregon pine (Douglas spruce) and redwood. It is a fact that large amounts of carbon dioxide issue from crevices in the rocks in some of the workings of the New Almaden mines, and it is known that some carbon dioxide also results from the decay of timber, and that it is found to a greater or less extent in all mines, but the fact that where this gas accumulates in excess, as at New Almaden, without having a noticeably bad effect on the timbers in the mine, suggests that there is some marked difference in these gases (the carbon dioxide issuing from fissures in the rocks and that emanating from decaying timber) not yet understood. Probably the latter consists largely of hydrocarbons.

There are various methods in use for preserving timbers for structural purposes, but these preparations mostly contain hydrocarbon compounds, and are not generally considered suitable for mine use underground.

In most cases the life of mine timber is determined by the amount of pressure it must sustain, and in many cases timbers are bent and crushed and split long before they have suffered great decay.

I regret that there is not more reliable data available upon this important subject, but hope that these few notes may result in a discussion which will give us more and much needed information on this practical and interesting matter.

### New Shaking Screen.

Herewith is illustrated the Wild shaking screen, which receives its motion from an eccentric placed

Wild's Shaking Screen.

on the drive shaft of the machine to impart a motion similar to that given to a screen or sieve in hand work—a thrust downward and forward at the same instant, the downward thrust to force the finished product through the screen, the forward movement to assist the oversize off the end into its receiving spout. The frame of the screen is made of bolted timbers; inside is the screen pan, supported by four hangers placed on the frame; the screen itself is tacked or screwed to a frame and held in place by wedges. New screens may be so placed. The thrust of the machine may be varied from a 1-inch throw to as small as desired, different points showing the throw being arranged on the eccentric.

The illustration shows the single wet screen with steel hopper. The screen for dry ores is furnished with dust-proof guard above screen and without lower hopper. The screen is also made double and triple, for both dry and wet work, screens being placed one above the other and all receiving the motion from the same eccentric.

The screen area is 9 square feet and the revolutions 325 per minute, giving 2925 square feet of contact per minute. A revolving trommel of the usual type and operating at the usual revolutions per minute, 36 inches diameter by 6 feet long, gives 1080 square feet of contact and requires 54 square feet of cloth.

The machine is asserted by the makers to have been in actual use for six months in various mills, and the stated results would seem to justify the manufacturers' claims of maintenance, capacity and durability. The capacity of the machine is stated by the manu-

facturers to be from fifty to seventy-five tons, according to the fineness of the mesh.

W. E. Wild is the inventor of the screen and it is manufactured and sold by The S. H. Supply Co. of Denver, Colo. Catalogues will be sent on request.

### The Central Eureka Mine, Amador County, Cal.\*

The deepest, and some of the most important, mines in California are in Amador county between Plymouth on the north and Jackson on the south. One of the latest mines to be developed in this section is the Central Eureka, the annual report of which was published herein in the issue of April 22. The mine was originally known as the Summit, and was successfully worked in the early history of mining on the Mother Lode. An ore shoot was discovered and worked at the north end of the property at that time through an old shaft. In 1895 the mine was reopened by the Central Eureka M. Co., under the direction of W. R. Thomas, who is still superintendent. Several shafts had already been sunk on the vein, the deepest being the most southerly one, which was down 700 feet when the new company commenced operations. This shaft was continued on the vein to a depth of 1000 feet, but until that depth was reached little ore of value was encountered. A drift on the 1000-foot level, however, cut three short and narrow shoots of pay rock. The shaft was continued downward and as level after level was opened at greater depth the three short shoots on the 1000-foot level were found to lengthen and get thicker, until the ends overlapped and formed practically a continuous shoot of ore over 600 feet long and, in places, 25 feet in thickness. At present the shaft is down 2300 feet with sinking in progress to the 2400-foot level. A connection was made with the South Eureka workings, adjoining on the south, at about the 1600-foot gear; it is then trammed to a 40-stamp mill which

day. There are twenty concentrators, and the concentrates are treated at the local chlorination works at Sutter Creek.

They use oil fuel for the boilers for the hoist, and electrical power for the mill and air compressor. The photographs and much of the accompanying information is furnished through the courtesy of Mr. P. L. Young of San Francisco, Cal.

This property has distributed forty-six dividends. During the past twelve months it has paid out \$320,000—or 80 cents per share in dividends.

### Mining Costs in British Columbia.

The annual report of the War Eagle Con. mine at Rossland, B. C., contains many items of interest to miners, as the manager has given to the stockholders of the company, and incidentally the public, the benefit of the itemized cost of mining at that property. The ore is chiefly iron and copper sulphide, with gold and silver values. The formation is greenstone schist, cut by intrusive dikes, and faults are numerous, which facts render development more expensive than in mines where the conditions are more regular.

The report contains a generalized statement for several years from 1897 to the close of 1904, but that for the year 1904 is of greatest interest, and is as follows:

DEVELOPMENT WORK.			
—January 1 to December 31—			
Work Done, Feet or Tons.	Total Cost.	Cost Per Ton.	
General work, stations, retimbering, etc.; machinery and equipment, re- pairs, maintenance, etc.	\$2,444 65		
Sinking main shaft.	6,344 33	\$36 15	
Sinking small shafts or winzes.	175 5	2,976 74	28 08
Raising.	105 0	34,442 69	17 77
Drifting.	1,938 0		
Total development work.	2,219 5	\$46,208 41	
ORE PRODUCTION.			
Ore from development work sold, tons	3,000		
Ore from dumps, storage, etc., sold, tons.	4,971	\$2,318 69	\$0 47
Stoped ore to mill.	4,304	10,381 03	2 41
Stoped ore sold.	48,780	123,879 60	2 54
Total ore sold.	61,064	\$136,579 32	\$3 24
SUMMARY.			
Expense of development per ton of ore sold.	61,064	\$46,208 41	\$0 76
Expense of production per ton of ore sold.	61,064	136,579 32	2 24
Total expenditure (per ton of ore sold).	61,064	\$182,787 73	\$3 00

TABLE OF COSTS, WAR EAGLE MINE, TWELVE MONTHS ENDING DEC. 31, 1904.

WHAT is claimed to be the record for windlass hoisting in the Klondike, and probably in the world, says the British Columbia Mining Record, was recently made in Gavin gulch, near Grand Forks. In the presence of fifteen other miners, who appointed judges and a timekeeper, Charles Cook, a man weighing about 140 pounds, is stated to have made good his boast that he could raise from a shaft on Gavin gulch fifty buckets in an hour, which work ordinarily takes from three hours and a half to half a day. In an hour, less fifteen seconds, Cook had hoisted fifty-five buckets of dirt, dragged the buckets to the edge of the dump, emptied them and returned them to the bottom of the shaft. Unfortunately, neither the depth of the shaft nor the size of the bucket used was given in the account published in one of the Dawson papers, but the test of strength and endurance was stated to have been thoroughly genuine and well authenticated.

It is not always the deepest mine with the great surface plant which is the most satisfactory to the owners. Some small properties, with comparatively small invested capital, have been highly remunerative to the discoverers or operators.

CONCRETE is growing in favor in construction and engineering work, and it has a very extended usefulness about mines in the building of foundations, walls, reservoirs, dams, and in many other ways.

\*See illustrations on front page.

# Mining and Metallurgical Patents.

PATENTS ISSUED APRIL 18, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

ROCK DRILL.—No. 787,376; J. M. Hamor, Philadelphia, Pa.

Combination, with cylinder, piston chamber and piston therein, and rotary valve and casing, of passage in valve casing adapted to be placed in constant communication with exhaust, channels in opposite sides of valve casing adapted to be placed in constant communication with supply, three channels in valve adapted in either position of valve to communicate with three channels in valve casing, respectively, and passages leading from ends of piston chamber to valve chamber, valve, in its two movements, causing exhaust channel in valve to connect with one or other of passages and causing one or other of supply channels in valve to connect with corresponding passage.

TUYERE.—No. 787,666; R. M. Downie, Beaver Falls, Pa.

Tuyere having air inlet, air outlet and open water outlet, means for introducing steam into tuyere and entraining air thereby through inlet, and means located in tuyere and path of movement of steam for condensing and collecting moisture thereof and directing same to outlet.

BRIQUET MACHINE.—No. 787,387; F. W. Meeker, Rye, N. Y.

Briquet machine comprising annular table supported vertically and laterally upon rollers mounted in eccentric bearings to allow vertical and radial adjustment of table, radial guide grooves in table, series of molds held within table, driving shaft, vertical shaft, intermediate gearing to transmit rotary motion from driving shaft to vertical shaft, horizontal

crank fastened to vertical shaft, crank pin at farther end of horizontal crank and sliding block mounted to turn on crank pin and engaging guide groove in annular table, whereby molds are successively presented to various operations; filling device; initial compression press; annular segmental plate beneath annular table; final compression press; dies fixed upon upper stationary head of final compression press; dies fixed upon platen of final compression press facing former dies and arranged to move with platen toward stationary dies during period of rest of annular table, and punching-out press for removing compressed material from mold.

SEPARATION OF METALS FROM THEIR ORES.—No. 787,814; J. D. Wolf, London, England.

Process of separating metals from ores, which consists in agitating pulps with oil until oil has taken up all metallic mineral contents with some gangue, separating mineral-bearing oils from pulps, removing suspended particles of gangue from oil by passing it through warm water and separating metallic minerals from oil.

FILTERING CELL FOR SEPARATING SLIMES IN ORE TREATMENT.—No. 787,736; G. A. Duncan, Deadwood, S. D.

In filtering cell, in combination with filtering bag closed upon all sides, frame within bag for extending same, comprising plurality of vertical spacing bars at relatively short intervals in length of bag; exterior check bars arranged in pairs, two of each pair being separate and locked opposite each other at opposite sides of bag, and slotted plates which receive corresponding ends of two bars of each pair for connecting them together at both ends for binding check bars against upper and lower side bars of frame.

PROCESS OF TREATING SLIMES IN ORE REDUCTION.—No. 787,878; G. A. Duncan, Deadwood, S. D.

Process of treating ore slimes which consists in accumulating slimes upon exterior of filtering cell im-

mersed in slime-bearing liquid, by suction from within cell and exhausting liquor from about such accumulated slimes, surrounding cell having slimes thus accumulated thereon with fresh metal solvent liquor, and drawing such liquor by suction within cell through slimes so accumulated on exterior, and subsequently detaching residual slimes from cell.

DRIVING DEVICE FOR PENDULUM MILLS.—No. 787,737; J. Durnholz, Kalk, Germany.

In driving device for pendulum mills, in combination, grinding pendulum *g h* resting on springs *c* by means of disk *b* in center over grinding surface and of single rolling body *n* inserted between disk *b* and another disk *m*, near periphery, disk *m* being rotated from outside and pendulum, being by springs pressed against rolling body, is moved thereby out of its perpendicular central position into inclined position with regard to grinding surface, which position is, in consequence of rotation of disk *m* and rolling around in circle of rolling body constantly changed.

AERIAL CABLEWAY.—No. 787,569; F. R. Freuch, San Francisco, Cal.

Hoisting and conveying apparatus, combination of hoist, trackway, carriage movable thereon, fall rope in two sections or units supported on carriage and at one end of trackway and extending to hoist, fall rope carriers and supporting means therefor, traction ropes, fall rope sections each supporting equal portion of load and means for operating fall rope sections and traction ropes correlatively.

PROCESS OF ROASTING ORES.—No. 787,540; S. B. Patterson, Phillipsburg, N. J.

Process for continuously roasting body of ore, intermittently feeding charges to top of body, intermittently subjecting body throughout its length to action of hot air, in intervals repeatedly subjecting lower portions of body that have been subjected to hot air to action of steam, and withdrawing roasted ores from base of body.

## Charters Towers District, Queensland, Australia.

Written for the MINING AND SCIENTIFIC PRESS BY C. M. NAYLOR.

Charters Towers, the premier goldfield of the State of Queensland, also the present leading goldfield of the eastern States of Australia, was discovered in 1872 by three prospectors, and since then has been one of the most consistent gold-producing centers that has been found in Australia. As usual with the majority of mining fields in their early history, the ore near the surface was rich and many hardy and deserving prospectors had their efforts of a lifetime rewarded.

The first mine which sprung into existence was the North Australian, which was worked out several years ago, but from which, in the early days, handsome dividends were distributed to its shareholders. Other mines were soon discovered and the same richness of ore continued near the surface. Since then the field has gone ahead by leaps and bounds, until to-day it carries a steady population of about 23,000 people, of whom over 5000 are directly employed in one or the other branches of the mining industry.

The principal reefs which have been worked for a number of years and have paid substantial dividends are the Brilliant, Day Dawn, Victoria and Queen, and the principal mines and dividends paid by each on the separate lines of reef are as follows:

Brilliant line—Brilliant P. C., \$3,400,000; Brilliant and St. George United, \$3,650,000; Brilliant Central, \$825,000; Brilliant Block, \$360,000; Kelly's Queen Block, \$700,000; Phobe, \$600,000; Brilliant Extended, \$90,000.

On the Day Dawn line are the Day Dawn Block & Wyndham, \$4,050,000; Day Dawn P. C., \$1,300,000; Mills' Day Dawn United, \$1,462,500; Day Dawn Gold Mines, \$300,000.

On the Victoria reef are the Victoria P. C., Victoria & Queen and the Victoria & Caledonia Block, which have paid a total of nearly \$2,500,000.

On the Queen reef are the Queen Cross Reef Co. with \$1,200,000 and the Band of Hope, New Queen and the Papuan, Brilliant and Victoria, which have a total dividend list of over \$1,000,000.

Another promising line of reef paying occasional dividends is the Ruby, and with the present prospects will in a few years, when properly developed, pay very substantial amounts to its shareholders.

The output of the field at present is about 25,000 tons per month, to which the Day Dawn Block and Wyndham contribute about 3000 tons, Brilliant Central, 3000; Brilliant and St. George, 2500; Queen Cross, 2000; Brilliant Extended, 3000; Brilliant Block, 1500; Mills' Day Dawn United, 1000, and several others with smaller outputs.

It is to be regretted that the total return of bullion for the year 1904 fell considerably below that of the record year of 1903, which was chiefly due to a falling off in the returns of the two principal gold producers, viz., the Queen Cross Reef mine and the Brilliant Central. In the case of the first, the mine was not worked as it should have been for the benefit of the field during the years 1902 and 1903, also part of 1904. During the latter part of 1901 a very rich vein of ore was discovered in the footwall workings and during the whole of the two years 1902-3 this shoot was the only one worked on, and was worked out regardless of the neglect in prospecting work from which other parts of the mine suffered. For the two years this ore was worth from \$50 to \$60 per ton, but during 1904 its value began to drop slowly but surely, until at the close of 1904 the value per ton of ore mined was from \$20 to \$25. Needless to say, during these halcyon days the shareholders' pockets swelled very visibly, but during the past few months the dividends have decreased over 50%.

In the Brilliant Central the value of the ore has decreased considerably during the past year. This is due to the quality of the ore in the footwall workings becoming poorer, which some time ago was unusually rich, and which when mined with the poorer quality from the hanging wall vein enabled dividends to be paid regularly, with an occasional extra.

Without doubt the prospects of the field generally are not as good as two years previous, but it is always a noticeable fact that at other times when prospects have been exceedingly poor something sensational has been struck and caused a general revival, and the case to-day is probably no exception to this rule. Two very rich prospects have been discovered in the vicinity of the town, one about 13 miles out, where an outcrop was found to be very rich, the first 100 tons being worth about \$100 per ton.

Another find, still richer, was discovered about 30 miles from town and the first crushing of fifteen tons of which gave a return of about \$200 per ton. This is also from an outcrop.

In the vicinity of both of these finds numerous claims have been taken up and the whole country will now be subjected to a good prospecting. One of the old-time large producers, Mills' Day Dawn United, which has been under a cloud for the past eight years, is again coming to the front on a newly discovered

vein of ore in their eastern ground, and this will soon probably be on the dividend list again.

The methods of work are somewhat similar to other fields when working on the same kind of reef. They are all incline reefs, the dip of which varies from 20° to about 60°, and taking a general view of the field the hanging wall country is very bad, chiefly composed of rotten diorite. This requires careful timbering which is carried out in the stopes on the "pig sty" or crib principal, and all the open spaces are filled with mullock (waste). Special large timber is very scarce in the vicinity, consequently expensive. The majority of the shafts are started vertical, and when the lode is intersected a curve is put in for the use of skips or a chamber is cut for a winch, driven by compressed air, to haul the ore up the incline shaft and the trucks transferred to a cage in the vertical shaft. There still remain a few incline shafts sunk from the surface, but they are now looked upon with disfavor, as the vertical shaft is always better for prospecting purposes. Ventilation is the one important thing which seems to give the mine managers an infinite amount of trouble. What with the small shafts that have been sunk from the surface, and the small workings in a large number of the mines, an insufficient amount of air for the men is the result, consequently the heat in some of them is almost unbearable, and the men can neither work anywhere near the whole time, nor do what is required when they are working. One advantage, however, is that the whole of the mines are practically connected with one another, which makes a large number of them much cooler, while in other cases it makes them warmer.

Development work with the rock drills, however, is the worst. In the larger number of cases the temperature is very high, and men work only with a pair of trousers and boots, and their garments are constantly saturated from perspiration. What is needed to-day in Charters Towers mining district more than anything else is a scientific method of working. I have no desire to rob the mine managers of the field of their just due, for, without doubt, they are as good practically as can be found anywhere, but mining is like every other business, and on that field they lack in scientific methods and proper organization. Until recently the idea of having a scientific man as manager of a mine was viewed with contempt among the greater number of miners, but since the appointment of W. A. McLeod as general manager of the Brilliant Extended gold mine that idea has been modified. The success with which this manager has met in his style of working is an "eye-opener" to the field, and I think the day is not far distant when men of his experience will be in demand there, and the sooner that technical men are given charge of the mines the better it will be, because the future of Charters Towers most assuredly lies in the successful handling of low-grade ore.

The metallurgical treatment of the ore is in a far worse condition than the mining, and the scientific man is far more needed here also. All the ore has to be transported some distance from the mines to the mills, as the latter have to be built where a plentiful supply of water can be obtained.

The Day Dawn Block and Wyndham companies have their batteries on the banks of the river Bendekin, some 10 miles from town, and branch lines are laid from the main line to the ore bins at the mine, and to the bins at the battery.

The Queen Cross Reef Co. have also a tram line  $\frac{1}{2}$  mile long to their battery.

In all the other cases the ore is carried in drays or wagons drawn by horses, which generally costs about 20 cents to 25 cents per ton for cartage.

Most of the batteries are fitted with rock breakers and elevators, but there are still a few who adhere to the primitive method of hand feeding—breaking the lumps with a hammer and throwing the ore into the mortars with a shovel. Happily, the latter is dying a natural death, and not too soon. The principal method of crushing is by stamps, and lately heavy stamps have been installed at most of the batteries.

At the Enterprise mill there are five Huntington mills, but there does not appear to be much difference in the work between these and the same amount of power in stamps. In these modern days of up-to-date methods in ore reduction it is surprising to see types of concentrating machinery long since recognized as inefficient, but here, until recently, they were in full swing, and such a thing as a modern concentrator was seldom heard of. In fact, the Enterprise mill was the only one that had them installed twelve months or so ago. During the last twelve months these things have been gradually changing for the better. Modern machines are now recognized as standard in the place of Berdan pans and other such devices, which ought to be on the scrap heap.

Cyanide plants are attached to every battery in the town, and it is here that one can see the technically trained man as "boss of the situation." There they have to have him, and consequently they are worked with every degree of success, and the amount of bullion which is lost after these men have treated it is of very little consequence.

I have tried to explain how much Charters Towers is in need of properly educated men in this branch of industry, and on him this town will now depend. With him there is every chance. The field will last for some generations, for as the time advances so

does the scientific man in the work. The untrained man, especially in mining matters, is too easy to sit down and let improvements and science go gaily on their way, but when the rich ore has all gone and his position depends upon the treatment of poorer quality ore, he finds himself supplanted by one who has followed and kept pace with the times, and that is what will happen some day on Queensland's premier goldfield.

Another great thing that deters this field is the want of necessary capital. Unfortunately, Queensland itself has fallen into the idea, politically, that she does not want the capitalist or moneyed man. Could a greater mistake be imagined for a young country to make, especially when in mining capital is of the greatest necessity?

Charters Towers is not the only sufferer. The whole of north Queensland is the same, for it is safe to say that no richer district in mineral wealth is known on the face of the earth than this. Mineral fields abound everywhere, and anybody who has been in the country will and must acknowledge the richness of such places as Cloncurry, The Etheredge, Croydon, Palmerville and numerous others, whose only difficulty is not being in railway communication with the rest of the world, thus rendering it impossible to have the ore sent to the smelters on account of the excessive charges for transportation. But the Queensland government has not the money to build the railways, and at the same time will not grant concessions to private syndicates to build them. If only this great Australian State would throw itself open to private enterprise in railway matters, its mineral wealth would be found to be greater than the imagination of the people who live in that country; but until the railways do open up all these fields the mineral wealth will lie there, a buried treasure.

An idea can be formed of the richness of the Cloncurry district when in 1871 this district and Arizona were looked upon as the great rivals for the copper production of the world. Arizona has gone ahead solely through railway communication, and Cloncurry would have been in the same place if such a railway policy had been pursued as is pursued in the United States.

As indicating the possibilities of Queensland as a field for the prospector, notwithstanding the fact that mining has been carried on here for many years, it may be said that new strikes are not of infrequent occurrence. Not long since a woodchopper discovered a vein while at work near Charters Towers. He had a quantity of the ore crushed in a custom battery and it returned over \$70 per ton. The gold-bearing rock is a dike of considerable size and longitudinal extent. The entire district about this discovery has been staked solidly for miles. A part of this vein or lode is described as a seam of kaolin stained black with iron and manganese oxide. Other discoveries are being made, and the general belief is that a new and valuable gold field has been discovered. About 150 miles from Charters Towers, on a stream known as Lucky creek, another strike is reported made by old prospectors, who have found a small vein 1 to 3 feet wide that runs about \$300 per ton in the mill. A rush to this latter place has also been made and hundreds of claims taken. At Lucky creek the water level has already been found at about 70 feet below the surface. The gold in these veins is worth about \$18 per ounce. The finds in these two districts have greatly stimulated prospecting in the country about for many miles.

## Diamonds in the Transvaal.

The extensive opening of the Premier diamond mine in the Transvaal brings to mind the discovery of numerous diamonds at various points in that State in its early history. A diamond weighing 4½ karats was found about 2½ miles from Pretoria, the capital, on the Hennessy farm in 1871, and several good sized diamonds were found in the gravels along Elands river. Two diamonds of value were found at Zoutpansberg, and in 1870 a diamond worth \$750 was found at Rustenburg.

In 1897 D. Draper of the Geological Society of South Africa made public the discovery of a diamond bearing pipe near Pretoria. Concerning this, Page's Weekly contains the following:

In 1897 Mr. Draper notified the members of the Geological Society that an interesting discovery of a diamondiferous pipe had been made in the vicinity of Pretoria. He had the permission of the owners to make public the fact that diamonds had been found in what appeared to be a small volcanic pipe, containing minerals closely resembling those in older known diamond mines. Garnets "carbon," olivine and other minerals associated with the diamond were there in abundance and eleven diamonds, one weighing 16 karats, and several smaller ones had been found in washing the blue. The interesting feature regarding this find of diamonds was that it was the first undoubted diamond mine found in the Transvaal, and as it was situated in the quartzites of the Magaliesberg, it was in a geological horizon much older than the Karoo shales of Kimberley, and also than the cave stones wherein the monastery diamond mine was situated.

### A Simple Stope Record.

Written for the MINING AND SCIENTIFIC PRESS  
by MATT. W. ALDERSON.

The readers of the leading mining journals are frequently advised of the value of good maps of underground development. Where a mine is fortunate enough to have an educated engineer in charge, or is developed to such a stage as to afford such a luxury on the staff, or as an occasional visitor to check up the record of development and make a map of it, this article may be of little if any value. It is only in recent years, however, that persons who think of following mining as a business or profession have considered the importance of a technical education in connection with their life work. In most sections it will be found that a majority of the mine operators have received the greater part of their education in the school of practical experience. Invaluable as

wishes to detail his work on a good-sized scale. For most map work the cross-section paper ruled in millimeter squares is preferable. This paper has larger squares of 5 centimeters, each centimeter being subdivided into four blocks 25 millimeters square. By letting each square on the paper represent a foot, we have in one paper 10 feet to the inch, and in the other a little more than 25 feet to the inch. Most mining engineers plat on a smaller scale, often 40 feet or more to the inch. This can be done easily, of course, with this paper, by making each square represent 2 or more feet instead of 1, but the beginner will find it easier to put in details he may wish on the larger scale.

The advantage of using the cross-section paper is that by making the map on a scale of 1 millimeter to the foot one may read at a glance each 5, 10 or 50 feet on the map, thus doing away with the necessity of measuring and figuring out distances according to the scale that may have been used.

Mining engineers would map several veins or

hole to mark the elevation and to save having to re-survey below that point. A 5-foot stick, with notches showing plainly each foot, is a handy measuring instrument.

The ground stope may be shown on the map by tinting in the squares. If shown by cross-hatching, the map will not present a neat appearance after a number of additions have been made. The tinting of the sections may be done with waterproof drawing ink, or, as an expedient and in getting practice, one may use an ordinary colored lead pencil. Thus, with simple tools, easily procured, one may make a map which will show plainly what has been done in the mine and what ground is untouched. With a little practice one may make a very neat map and show on it such details as are of particular interest in his property. As a matter of course such a map as here suggested could not be depended upon for the accurate location of certain underground points in the event of it becoming necessary to make an expensive connection with some distant point, but for

The Lucky Tiger Mines, Sonora, Mexico.

this experience has been, it nevertheless has its limitations. At the same time it is these practical men who are quick to see the value of suggestions for saving time or enabling one to do his work to better advantage.

It is possible that many persons neglect making maps of their work because they are not familiar with a way in which it may be done, and imagine it to be quite a complicated affair. But oftentimes that which we think must require long training is exceedingly simple when once understood.

The advantage of a map is that one may ascertain the exact location of work without having to enter the mine for the purpose. In fact one cannot have a clear and comprehensive idea of what work has been done in the mine and what ground may be available for stoping without a map.

The writer has found a very simple way of keeping his mine maps by the use of cross-section or profile paper—that is, paper with lines crossing it vertically and horizontally—obtainable of any stationer dealing in supplies for engineers. There are two kinds of this paper especially adapted for this work. The first is ruled in squares of 1 inch, with ten crosslines to the inch each way. This is convenient where one

branches of the same vein on one sheet, tinting the separate ore bodies with different colors. But it will be well for the beginner to map each vein by itself. The stope map is made to represent the vein as if the hanging wall were removed and we were looking down upon it from that side.

Commence the map by laying out the levels. In doing this never take account of their grade, but run the lines as if the levels were really level. Take no account of inches; for a few inches one way or another does not make any material difference. Thus the level may be mapped as 6 or 7 feet, regardless of its being 6 feet 2 inches, or 6 feet 10 inches. Map according to nearest height. Next map in the shafts, chutes and manways. Then map in the raises.

In the mine, in securing the data of the stopes for use on the map, it will be convenient to carry a small memorandum book, ruled with cross-section paper. Let each cross-section represent a foot and each page a raise above an ore chute. In mapping raises partly made, one may cut a notch in the last cap, or mark the wall so he may know the point to which he has finished his survey. A good way to do this is to drill a hole an inch in depth at each 10 feet. Sometimes I have placed Roman numerals alongside the

the purposes above set forth it will prove of great value to the practical mine superintendent.

### A Mexican Gold Mine.

In northern Sonora, Mexico, is a group of gold properties known as the Lucky Tiger Combination. The property is in the Moctezuma district, near the town of Opoto. The offices of the company are in Douglas, Ariz. The mine, when discovered, was far from public highways or railroads, and the first thing the company did upon coming into possession of the property was to build a good wagon road over which to transport supplies to the mines, and to take out ore. The accompanying engravings convey a good idea of the country through which the road was built, and also something of the nature of the mining work since done there. The ore bodies have been extensively developed since then, and it is said there is a large body of free milling ore in sight, beside which hundreds of tons of high-grade ore have been shipped to smelters. The veins are large and well defined, having heavy iron outcrops. Minerals present are gold, silver, silver sulphides, galena, zin

blende, wulfenite, and a variety of secondary products of the oxidation of the sulphide ores. Some of the ores offer difficulty in treatment, due to the presence of antimony. Manganese oxide and copper are also found in some parts of the mine. The wall rocks contain a great deal of finely disseminated pyrite, but this is usually low grade. There is an abundance of timber available, and the water supply is said to be sufficient for present needs.

### Place and Value of Small Scale Ore Tests.\*

NUMBER II—CONCLUDED.

Written by ERNEST H. SIMONDS.

In order that the results of laboratory tests may be reliable, it is necessary, of course, that the sample on which the tests are made should correctly represent the ore which is to be worked. The only proper way to take this sample is to take samples throughout the mine in exactly the way that would be done if the mine were being examined for sale. In quartering down the sample to get the assay pulps, two quarters are saved after the sample has been crushed to  $\frac{1}{4}$ -inch mesh. After the samples have been assayed, so that we know which represent ore and which waste, an amount of each one of the samples representing ore is weighed out which cor-

The work is checked by the values as shown by the assays of the ore being accounted for in the products; 30.75 grams of mercury were used in this test, and only 26.1 grams of amalgam recovered, the amount lost, about 15%, going into the concentrates. The amalgamation part of the test was, therefore, repeated; 30.20 grams of mercury were used, 29.95 grams of amalgam recovered and an extraction of 32.6% of the gold and 0.7% of the silver obtained. Allowing for the loss of amalgam in the first test, the extraction of the gold would be 33.6%. As a further check on the test, it may be mentioned that while the average assay of the mixed slimes and tailings in the test is 0.075 ounce gold and 7.15 ounces silver, the tailings from the fifty-ton mill, whose feed was accurately represented by the sample used for the above test, assayed at the same time 0.07 ounce gold and 7.15 ounces silver.

The above test shows, besides the assay values of all products and the percentage of total value in each product, that there will be an extraction of 88.75% of gold and 58.3% of the silver, and that the ore was crushed too fine, since the slimes assay higher and contain a larger percentage of the values than the sands.

In making the above test, the ore crushed to a size corresponding to the 35-mesh on the battery, was shaken hard for one-half hour with the mercury and water so as to flour the mercury through the ore well; the pulp was then diluted and the mercury sep-

slimes were separated, weighed and assayed, giving these results:

Product.	Gold Assay Value.	Per Cent by Weight.	Per Cent of Value.
Sands.....	\$2.80	77.25	64.7
Slimes.....	5.25	22.25	35.3
Total.....		99.50	

Hence both sands and slimes are valuable and will need to be worked. A test in a percolator showed that the tailings as received—the slimes and sands together—leach readily. Therefore, it would appear that amalgamation and concentration are extracting all that they can, but that the tailings may probably be treated without difficulty by cyanidization. As showing that small-scale tests agree with mill operations, I may mention that, on reporting as above, I was informed that they were already cyaniding the tailings with success, but had the test made in order to satisfy themselves that the mill was doing as well as it could before cyaniding.

To show what can be done in the investigation of sulphurets by small tests, I give the following results:

Test.....	1	2	3	4	5
Mesh.....	Conc.	Conc.	Slimes.	Slimes.	P. Tails
Weight of ore, grams.....	50	50	50	50	100
Strength solution, lbs., per ton.....	2	5	2	5	5
Volume solution, grams.....	200	200	200	200	100
Lime, per ton, lbs.....	5	5	5	5	5
Consumption, lbs., per ton ore.....	4.4	6.8	0.8	2.0	Lost
Assay tailings.....	\$4.55	\$3.30	\$2.96	\$2.05	\$0.30
Extraction, per cent.....	80.4	86	89	92	80

The results show conclusively that these slimes and

Lucky Tiger Mines, Sonora, Mexico.

responds to the stoping width at the point where the sample was taken. These samples are thoroughly mixed, and we have a sample for the tests which is an epitome of the mineable ore in the deposit as shown by the present state of development of the mine. Besides this average composite sample, on which all extraction tests will be made, specimens should be taken of varying aspects of the ore, showing the condition of the gold in rich specimens, the different sulphides in the mine and the character of the wall rocks. These are taken to show the form of the gold, silver, copper or lead minerals, and to make it possible to determine, by assays of different specimens, with which minerals the values are combined.

In order to exemplify the variety of information which may be obtained in regard to an ore by simple laboratory tests, I will outline the methods and state the results of a few such tests:

#### I.—LABORATORY MILL TEST.

Product.	Weight.		Assay.		Product Contained Per Cent of Values in Ore.	
	Grams.	Per Cent.	Ounce Gold.	Ounces Silver.	Per Cent of Gold.	Per Cent of Silver.
Ore.....	1000	100.0	0.50	13.75	100.0	100.0
Amalgam.....					29.25	0.7
Concentrates.....	322	22.2	1.34	35.70	59.5	57.6
Sands.....	418	41.8	0.035	2.25	3.0	6.9
Slimes.....	362	36.2	0.12	12.80	8.0	33.7
Totals.....	1002	100.2			99.75	98.9

\*Trans. Cal. Min. Assn.

arated by vanning, the sulphurets being then concentrated out by about a dozen washings on a batea 14 inches in diameter, washing back and forth from one disban to another, until it was seen that the tailings were about as free from sulphurets as vanners well run could be expected to leave them—say, not more than 5% of the mineral originally present. The concentrates were not allowed to have more than 15% of gangue. The slimes were separated from the sands by decanting the muddy water, adding clear water, agitating and decanting again, this being repeated until the water came off clear. Each product was then dried, weighed and assayed. The concentrates can be analyzed for copper, lead or anything likely to affect their further treatment, while the sand and slimes can be used for tests by cyanidization.

To show what can be done by small tests in showing how to reduce the values of the tailings in a mill already running, I will give the following results on a sample of tailings assaying \$2.95 per ton in gold. Exactly the same laboratory mill test as above outlined was made on the tailings as they came from the mill. Two thousand grams were used for the test. The amalgam contained only 0.10 milligram of gold, indicating a value of only 3 cents in free gold per ton of tailings. There were only a few specks of pyrite or heavy concentratable mineral of any kind—surely less than one-tenth of 1% of the ore by weight. The concentrates were, accordingly, not saved but allowed to go in with the tailings. The sands and

sulphurets, when ground fine, give a good extraction<sup>1</sup> with a small consumption of cyanide.

Another lot of sulphurets carrying fifty-six ounces of silver and one ounce of gold was tested in the same way and found to give an extraction of only 40% of the silver and 70% of the gold. Tests were then made by roasting the concentrates in a large, new muffle and smelting them together in a graphite crucible with ore from the same mine carrying 22% of sulphurets, using equal weights of roasted concentrates and raw siliceous, sulphide ore. Two thousand grams were used for the roasting test and 500 grams for the smelting test. It was found that there was no loss of either gold or silver in the roasting; that the smelting gave a matte fall of 14% of the weight of the charge, effecting a concentration of 7 into 1, the matte assaying 6.50 ounces gold and 285 ounces silver, and effecting a saving, even in the crude work done in the small crucible, of 96% of the gold and 91% of the silver.

There are certain general considerations which, it seems to me, have never been stated with sufficient clearness in the treatment of this subject, and I am glad to present them to you:

1. The purpose of any test, however made, is to get information and not to work ore.

2. Some things about an ore are just as well represented and just as evident or capable of being found out in a representative pound sample as in a mine full. For example, lots of one to several carloads are valued on the smelting, in assaying, of

a few ounces of ore more accurately than in any other way. Within my experience, lots of rich material worth \$10,000 to \$25,000 have repeatedly been valued with an agreement satisfactory to all concerned by a smelting of less than an ounce of the pulp. Just as the value of ore can be accurately determined by small scale tests, so can many of its other characteristics.

3. A very wide range of information can be obtained quickly and cheaply.

4. Ore tests are either mechanical, as concentration, or chemical, as smelting tests, in their nature; or they may partake of both, as in leaching tests.

5. The purpose of a laboratory test, either of ore or of mill products, should not be to parallel the mill, to determine how much some old machinery, perhaps insufficient in amount, deficient in design or unskillfully run, will extract, but to determine what percentage of the values in the ore can be extracted by the best possible plant.

6. Small scale tests have the advantage that all the details are under ready control, difficulties of sampling are obviated or minimized and the "clean-up" can be performed with an accuracy approaching that of chemical analysis. Only fifty pounds of a representative sample is sufficient for a large number and great variety of tests. The results serve, we might say, as a small scale or key map to indicate in what direction to make tests in greatest detail, where the correct solution is to be found.

In conclusion, we may say that the results of small scale tests chemically may be relied upon with confidence, but mechanically they need to be interpreted by one familiar with the work both in the mill and in the laboratory. While their results are not precise, they are approximately correct, if made with good judgment, care and skill on representative samples. They not only give a wide range of information as an aid in deciding upon the best general method of treatment, but they give the best help to be had in investigating difficulties and improving details of a method of treatment already in use.

### Vertical Boiler Feed Pump.

The Cameron vertical boiler feed pump is illustrated herewith. The photographic reproduction shows a

Vertical Boiler Feed Pump.

plain unassuming vertical piston pump on base. Its makers assert that it possesses every necessary attribute of a perfect direct-acting pump, occupying but little space and giving the maximum capacity. Although shown on a base plate, it is sometimes preferred for marine use to bolt the pump, by means of lugs cast on the back, to the bulkhead. This has been done in the case of pumps of this type furnished to the smaller gunboats and which have seen service in the United States navy. In common with all Cameron pumps, no working part is exposed except a small part of the rod, which may also be covered, if necessary. The makers say the steam end may be adapted to work any steam pressure, no matter how high, and the water end is fitted with Cameron patent priming valves, and a removable bushing or lining, which may be taken out and replaced with a new one in a few minutes, thus avoiding any delay when it becomes necessary to renew the working barrel of the cylinder on account of wear. Those

desirous of further facts relating to any type of pump made by the A. S. Cameron Steam Pump Works can address foot East Twenty-third street, New York City, N. Y., for pamphlet.

### The Bullfrog District, Nevada.

TO THE EDITOR:—Bullfrog district is situated in Nye county, in the southern portion of the State of Nevada. It can be reached via Tonopah and Goldfield, or from Los Vegas, a station on W. A. Clark's new railroad which runs from Los Angeles, California, to Salt Lake City, Utah.

The district is on a spur of the Grapevine range of mountains through which courses the Amargosa river, whose bed is dry for the greater part of its length. Water can easily be obtained, however, by digging down a few feet, and at intervals a small stream can be seen flowing, but it is soon swallowed up by the dry and greedy sands.

There are four so-called towns in the district—Bullfrog, Gold Center, Beatty (which is the post-office), and Rhyolite, near which are grouped the principal mines discovered up to the present.

The original Bullfrog mine, which gave its name to the district, is about 3 miles west of the town of Rhyolite; it is a "blow out" of quartz between limestone and porphyry rising up into a small knoll at the base of the main range having almost the appearance of a small butte rising directly out of the plain. It is apparently about 300 feet in length, 200 feet in width, and 75 feet in height above the surface at its base. A drift has been run into this little knoll of quartz 100 or more feet and four crosscuts from this main opening show the quartz body to be seamed with horizontal and vertical strata of a greenish, bluish-colored ore resembling both malachite and lapis lazuli. It is called by some bromide of silver, but regardless of its exact name there is no mistake to be made in calling it high grade ore. The purple-bluish mineral is fluorspar. The ore strata are from 1 inch to 6 inches in thickness, "criss-crossing" in many places and forming a network. Free gold is easily discernible to the naked eye in the greater portion of these greenish-colored streaks; the statement made by the management that a shipment of ten tons of assorted ore yielded in the neighborhood of \$1000 per ton in gold and silver can be readily believed, and the additional claim made that the ore body for 50 feet in width will average \$50 per ton does not seem unreasonable. The Denver, Montana-Bullfrog and Tonopah-Bullfrog, the National Bank and Shoshone mining claims, the latter owned by E. A. Montgomery, are within a stone's throw of the town of Rhyolite. All of these properties show high-grade gold and silver ore. The Shoshone or Montgomery claim, situated on the divide between the towns of Beatty and Rhyolite, is a porphyry dike between altered rhyolite and trachyte walls. The dike is fully 50 feet in width, as disclosed by a cross-cut tunnel driven into it, and shows good ore its entire length. A width of 27 feet of this ore is said to average \$200 per ton in gold and silver. Ore is being sacked and shipped to the smelter via Los Vegas as fast as teams can be engaged.

The miner who comes into this section to prospect for or to purchase mines must not expect to find "regular fissure veins." There are no croppings of pay quartz with regular walls, clay gouges, slickensides, etc. The base of the mountain chain here is limestone through which the rhyolite peaks have been pushed upwards; flanking these craggy crests and ridges, spires and minarets of black and chocolate hued rhyolite, are dikes and bands of white porphyry and altered trachyte, coursing north and dipping to the east. From a superficial point of view the geology of the district does not seem at all complex, and judging from the mines already discovered more will be found in the shape of ore chimneys capped over, but near the contact of the clay porphyries with dissimilar formations.

From the excellent showing so far made here it is surprising to find so little actual mining work going on. Not over fifty miners are employed in all the mines in this neighborhood and miners in search of employment will be disappointed if they come here expecting to find ready work at the present time.

The district has been staked solid for 9 miles in all directions from the sagebrush flats, including part of the desert, to the tip of every summit in sight. Some have located as many as 100 claims. According to the local laws, all locations must have their corners put up and assessment work done within ninety days after locating the ground. If honestly adhered to, this rule would call for much assessment work, but it is evaded by the wily land grabber, who finds it easier to relocate his ground before the expiration of the ninety days prescribed than to comply with the law. Of course this hoggish policy is keeping the district in the background, as very little development is being done away from locations contiguous to the few mines discovered which show pay rock. Locations in the neighborhood of mines that have a showing of ore sell readily whether they have anything in sight or not. Claims with nothing but sagebrush, greasewood and four stone monuments in sight, provided they are in the neighborhood of pro-

ducing claims, sell for \$500 to \$2000 in cash. Town lots sell for \$25 to \$1000. There are very few lumber buildings, nearly all the towns being made up of tents. Water is \$2 per barrel, hay \$100 per ton, lumber \$112 per M., freight \$80 per ton, flour \$8 per 100 pounds. Supplies of all kinds excepting lumber are here in fair quantities. As yet the weather is quite cold. Although warm in the middle of the day, three pairs of blankets are a necessity at night; thermometer ranges from 94° to 20° during each twenty-four hours. There is no sickness; every one seems happy, healthy and confident of the future.

Rhyolite, Nev., April 20. CHARLES L. LANO.

### THE PROSPECTOR.

The prospector can make a convenient set of instruments for testing the hardness of minerals by securing suitable small crystals or fragments of the harder minerals. These can be inserted in jewelers' cement set in the ends of penholders. This makes a convenient instrument for the purpose and not easily lost. The prospector should have all the minerals of the scale of hardness, except the diamond, which is not necessary. The minerals of the scale are as follows: 1. Talc (the steatite or French chalk of the tailor). 2. Gypsum (selenite, the transparent variety). 3. Calcite (crystallized, also called Iceland spar, and determined by its strong double refraction). 4. Fluorite (the fluorspar of the lead and zinc mines, also abundant in Cripple Creek, Colo., in the northern Black Hills, Castle Dome and elsewhere in Arizona, and recently found in the Bullfrog district of Nevada). 5. Apatite (a calcium phosphate). 6. Orthoclase (the common potash feldspar of granite, often pink in color). 7. Quartz (crystal). 8. Topaz. 9. Sapphire. 10. Diamond. Topaz is not usually easy for the prospector to get, nor is the sapphire; but for the latter corundum may be substituted. The diamond is unnecessary, as any mineral which corundum will not scratch is probably diamond. A small file and a good knife are useful in testing the hardness of the softer minerals, from talc to orthoclase. The relative hardness of these minerals is determined by the amount of pressure necessary to scratch it with a knife or file. The edge of a broken plate makes a good streak plate, but usually the streak can be determined by means of the knife or by pulverizing a small fragment and noting the color of the powder. A small magnet is also useful, as well as small bottles of nitric, sulphuric and hydrochloric acids and ammonia. All these must have glass stoppers. Hypo-sulphite of soda and sodium or calcium sulphide are useful to test silver chlorides and bromides.

The rocks from "W. B.," Challis, Idaho, are volcanic rocks and both are of the type known as amygdaloid. No. 1 contains abundant zeolites, both white and green, and also a smaller amount of chalcedonic quartz. No. 2 contains mostly chalcedonic quartz, with a few zeolites. The latter are decomposed by hydrochloric acid. These rocks were originally fluid lavas flowing on the surface and were filled with bubbles of air or gas. Subsequently, on cooling, these gas vesicles were filled by the infiltration of chalcedony and zeolites. The rocks contain no ores except those of iron—magnetite. The green color is probably due to iron silicate.

The rocks from Sberidan, Mont., are: No. 1, hornblende granite. It consists chiefly of hornblende, quartz and feldspar (orthoclase and plagioclase). No. 2 is similar to aplite in composition (quartz and orthoclase), but is coarser in grain than typical aplite. It also inclines to graphic granite, but is not typical. It is a micaless granite. No. 3 is augite granite, an unusual rock. No. 4 is a fine-grained biotite granite. No. 5 is chiefly limonite—iron oxide.

The three mineral specimens from Canyon Ferry, Mont., are hard hematite, an ore of iron, very common in nearly all placer mines. It resembles tinstone, perhaps, to the unpracticed eye, but it is softer and of a lower specific gravity than cassiterite and lacks the luster of the latter. Tinstone makes a pearly brownish to gray powder, hematite a red, earthy one.

The rich, deep azure blue found in ores is usually azurite (the blue copper carbonate). There is no silver bromide known having this deep-blue color. When silver bromide is so colored it is due to the presence of copper carbonate. Silver bromides and silver iodides are usually of a peculiar greenish yellow cast and can not be called blue by any one who is not color blind.

The mineral specimens from Isabella, Cal., are: No. 1. Zincblende, with quartz; a little yellow copper ore; chalcocopyrite. No. 2. Garnet.

THE Broken Hill mines of New South Wales were discovered and opened in 1884-85. They at first produced lead-silver ore in great quantity. The zinc and copper were developed in the deeper workings of the mine.

## Precipitation of Gold and Silver From Cyanide Solutions.\*

Written by W. J. SHARWOOD.

The cyanide process for extracting gold and silver from ores and tailings has now been practiced on a large scale for about fifteen years, though occasional attempts had been made long before to utilize the solvent action of alkaline cyanides on gold. When once established as a working process, numerous methods of increasing its efficiency suggested themselves, and many real and supposed improvements have been proposed, some dealing with the mechanical problems of handling the material, others with the dissolving of the precious metals, and others with the equally important question of getting them out of the solution again. In this paper I wish merely to treat of some of the details of the latter question—the recovery or precipitation of gold and silver from their cyanide solutions.

In considering this subject, one point is to be noted. Most other processes in metallurgy consist of a series of steps, in each of which the valuable contents of the original material are concentrated to a greater or less extent. Thus, in smelting a 15% copper ore we would get probably a 50% copper matte, or in chlorinating sulphurets worth \$100 per ton we would get a solution much richer in gold. In the cyanide process, on the other hand, the dissolving of the gold generally gives us a solution poorer in gold than the material originally treated, for the weight and volume of the gold-bearing solutions are usually considerably greater than those of the tailings or ore. Thus, at a slime plant using decantation, where from three to five tons of solution are obtained from one ton of slime, the average solutions are necessarily of very low grade. For instance, at one plant over a thousand tons of solution are precipitated daily, of an average value of less than 50 cents per ton in gold, or less than one part of gold in a million. From solutions so dilute as this it is not as easy to secure a high percentage of precipitation as from the rich solutions which are often used in laboratory tests.

Of the gold in a cyanide solution, the greater portion of it can be quite readily precipitated, but it is a more difficult matter to get out the last few per cents, and almost impossible to extract the last trace.

One often hears the expression, "Precipitation at this plant is practically perfect," when, as a matter of fact, 20 cents to 30 cents' worth of gold may be left in every ton of the solution. As the solution is to be used over again, this gold may not at first sight seem worth troubling about, but it must be remembered that it is impossible to recover all of the solution run upon a charge. Whether it is leached or agitated, a certain proportion is retained, no matter how thoroughly washed, and especially is this source of loss to be considered in the case of solution which is to be added just before the "wash water" of the leaching process, or in any of the later "washes" of a decantation system. The question as to how closely it pays to precipitate should be looked into carefully—a comparatively rich solution may be run with safety upon a free-leaching charge in its earlier stages, but solution added toward the end should have been precipitated as nearly perfect as possible. In the decantation process it is easy to calculate how large a proportion of any particular wash is going to be thrown away with the residues. Methods of precipitation may be classified into:

**CHEMICAL METHODS.**—That is, precipitation by addition of salts or acids, or by passing gases into the solutions. These methods, I believe, without exception, render the solution unfit for use in treating further quantities of ore, unless some further treatment is applied. Hence, as a rule, they are only available for solution which is to be run to waste.

**CHARCOAL PRECIPITATION.**—Filtration through charcoal is in use in certain parts of Australia, the material being revived by occasional reburning, while a cleanup is conducted by burning the coal and fluxing the ash.

**ELECTROLYTIC METHODS.**—Precipitation by a current from a dynamo or other outside source. This may be applied in two ways: First, to the clear solutions obtained by the leaching or decanting process; second, to the cyanide pulp itself while in course of agitation, as in the processes of the Pelatan-Clerici class.

Another electrolytic system now uses iron plates, covered on one side with a carbonaceous coating, the gold being deposited on the unprotected side. The tank is filled up with solution; this remains until practically all the gold is precipitated, when the solution is drawn off and a new batch is run in. The process is, therefore, an intermittent one.

**PRECIPITATION BY METALS IN A FINELY DIVIDED STATE.**—The more electro-positive metals or their alloys can be used. Aluminum, sodium amalgam and zinc are about the only ones economically possible, while only zinc and its alloys have so far stood the ordeal of practical work.

(TO BE CONTINUED.)

\* Abstract Trans. Cal. Min. Assn.

## MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

### ALASKA.

W. Scott has commenced work on the Vulcan M. Co.'s tunnel on Silver Creek mountain, near Windham.—E. Wisnom and A. Bergen are building a bridge for the Golden River M. Co. across the Shuck river near the Ten Mile canyon, near Windham.—E. E. Taylor is building a 1-stamp mill on the Jack Pot quartz claim, near Loch Mary.

The Apollo M. Co. is running a crosscut tunnel on Unga Island, in Behring sea, 800 miles west of Nome. Louis Schloss & Son of San Francisco are reported to have a 60-stamp mill on the property. F. R. Brown is superintendent.

### ARIZONA.

#### Gila County.

H. Strong, who is in charge of the Pinto Creek M. & S. Co.'s mine, the Yo Tamhien, in the absence of Superintendent D. P. Fuller, reports that good progress is being made in driving the lower tunnel, although the ground is very hard. Machine drills are being used.—F. Thompson is developing claims 12 miles south of Bowie.

#### Mohave County.

Work on the Elkhart mine, at Chloride, is expected to have the mine unwatered and sinking in progress within a month. It is reported that they will unwater and work the Tennessee and Schuylkill mines, which carry high-grade lead ores.—L. D. Godshall, manager of the Arizona-Mexican M. & S. Co., has let a contract to sink 100 feet on the Twins mine, Cerbat.—It is reported that rich ore has been found in the stope from the tunnel level of the New Jersey mine, near Chloride. T. B. Lamb has charge.—L. B. Davenport reports that in the bottom of the lower tunnel on the Eldorado mine, Gold Basin, a 10-inch streak of ore was recently cut that gave an average value of \$4 a ton.—The Blue Ridge M. Co., near Vivian, is running its mill on ore from the Hilly mines. It is reported that a larger saving of values is being made than at first expected and that for the present it is not intended to put in a cyaniding plant.—T. McMahon is opening a copper property below the Alpha mine, at Layne Springs.

#### Pinal County.

(Special Correspondence).—At the McCallum-Schillings property the mill has been started up. The Big Lead M. Co., operating this property, is opening up the 130-foot crosscut level.—For the Middy mine, 1½ mile from Kelvin, 300 feet of track and a car have been put in, to be used in running a 300-foot tunnel in the mine. Kelvin, April 24.

Superintendent W. B. Twitchell of the Big Lead M. Co., operating the McCallum-Schillings property at Ray, has started up the old Bobtail mill, on ore from the Big Lead. They are opening up the 130-foot crosscut level. They expect to put in a leaching plant as soon as the storms are over.

#### Yavapai County.

(Special Correspondence).—M. J. Brophy and F. S. Douglas have sold the Garfield mining claim at Junction for \$112,000. Junction, April 24.

#### Yuma County.

(Special Correspondence).—A Los Angeles company has been organized to work placer ground 10 miles from the Colorado river, in Yuma county. The company is known as the Gold Placer Prospecting Association and is planning to put in machinery and work the claims. Yuma, April 24.

### CALIFORNIA.

#### Amador County.

The Bunker Hill mill, near Amador City, has been temporarily hung up while more development work is being done in the mine.—The last payment on the Bay State, now a part of the Rbeta Con. M. Co. of Plymouth, has been made. The 10-stamp mill is running steadily. At the Bay State the shaft is down 1030 feet.

#### Calaveras County.

It is reported that the 3-stamp mill of the Red Bird mine, near Vallecito, owned by C. D. Smith, is to be replaced by one of greater capacity.

#### El Dorado County.

The Gold & Silver mine, between Placerville and Kelsey, is employing twenty men and a mill is to be built.—The New Highland G. & C. M. Co. is preparing to commence work on a tunnel to tap new ground on the Mameluque Hill, near Georgetown. The tunnel will be started in Illinois canyon. The mine will be operated by the hydraulic process and the debris will pass out through sluice boxes placed in the tunnel.

#### Fresno County.

It is reported that the Associated Oil Co. (the Southern Pacific Co.), which has no contracts in the Coalinga oil field, has taken advantage of the increased production in the district to cut the price of oil to 15 cents per barrel. The Coalinga Oil Transportation Co., which is the only important rival of the Associated in the local fuel-oil market, is shipping as much oil as the latter, its receipts being principally from holders of contracts at 19 and 20 cents. The Coalinga oil producers have completed plans for the construction of a pipe line from the oil field to Alviso, at the southern end of San Francisco bay.

#### Mariposa County.

H. L. Waste, assistant manager for the M. C. & M. Co., is running the ashes from the Mariposa mill, recently burned, through sluice boxes, as considerable gold and amalgam were in the floor and the troughs.

#### Mono County.

General Manager W. A. R. Loose of the Field of Gold M. Co. of Masonic and Bodie, Ed Loose of Utah, J. E. Twelves of Provo, Utah, and W. Hatfield have taken up 800 acres of land and a water right on the Walker river, 6 miles below Bridgeport. It is reported that they will put in an electric power plant to transmit power to Bodie, through Masonic and on to Tonopah. A flume 3 miles long, containing 2,000,000 feet of lumber, will be built to gain the power required. The old Syndicate mine in Bodie is under their control and the mill is being refitted preparatory to continuous work.

#### Nevada County.

The machinery on the Great Dane mine, at Selby Flat, is being moved to the Morning Star mine, at Badger hill, 6 miles from Nevada City. The Morning Star is being opened by P. Deidesheimer & Co., and the shaft is down 70 feet.—It is reported that rich rock has been found in the Ethel mine, near Gaston, which is being worked by Maltman, Humphrey, Myers & Goodwin, who intend to build a 10-stamp mill.—At the Star mine, near Gaston, the tunnel is being extended.—Over eighty men are employed at the Gaston mine and the big mill is kept running night and day, by Superintendent F. Miller.

It is reported that the North Star M. Co. is to build an electric road from the North Star mine to the Central mill and cyanide plant, replacing wagons now in use.—C. L. Canfield, head of the drift mining enterprises A. Blue Tent and Grizzly Hill, north of Nevada City, has secured 2700 acres of gravel mining land, beginning at the Blue Tent claim and extending along the main Red Dog and You Bet channel to Scott's Flat for 3 miles. Surveys are being made for roads and for the bedrock tunnel, which is to head in Sailor ravine, from which point it will have to run about 3000 feet to reach the channel. As soon as gravel is reached a 40-stamp mill is to be erected in Sailor Flat ravine, near the mouth of the tunnel.

#### Placer County.

(Special Correspondence).—The Belvue mine at Ophir, under the direction of P. Cozano and A. N. Buchanan, made a recent shipment of thirty-four tons which is reported as giving eighty-seven ounces free gold. Auburn, April 26.

The Cash Rock mine at Forest Hill has commenced work for the season under the supervision of R. Jones.

#### Plumas County.

The Northern placer mine, near Cromberg, has been bonded by P. Traynor to Long & Cronan of San Francisco. W. E. Ramsdell is superintendent at the mine and will start hydraulic mining.

#### Shasta County.

(Special Correspondence).—The smelter of the Great Western Gold Co. was shut down temporarily to repair a turbine pump, and not because of fault in the process. The construction of roasting stalls is contemplated to treat some of the ores more economically. H. Haas has charge of the reduction works. Ingot, April 25.

It is reported that a 700-ton smelter is to be put in at the Balaklava mine, near Kennett. P. L. Kimberley of 220 Bush street, San Francisco, Cal., is president.

Manager L. T. Wright of the Mountain Copper Co. says that the smelter at Keswick will be closed about May 5, so that a part of the machinery can be moved to the new smelter being built at Bull's Head Point, near Martinez, Cal.

#### Sierra County.

Superintendent W. D. Pinkston of the Sierra Buttes mine, at Sierra City, has made arrangements to put in a new 40-stamp mill and cyanide plant.

#### Siskiyou County.

The Yreka Creek Gold Dredging Co. has bonded land along Yreka creek and is building a modern dredger to be run by electricity. E. T. Wallace of Yreka is vice-president.—J. S. Beard, C. W. Nutting and F. G. Smith of Etna have bonded the Steamboat and the Accidental gravel mines on McAdams creek to W. A. Fish of Tehama, who proposes to dredge the gravel.—It is reported that the King Solomon Co., near Black Bear, have struck their ledge and will resume work under direction of W. H. Young.—The tunnel being run at the Black Bear mine to tap the lower works is in 150 feet.

It is reported that F. T. Marker, of Nevada City, has bonded the Jim Wayne, above Fall creek, near Thrall, to a San Francisco company of which C. W. Porterfield is superintendent. A small force is now at work and more will be put on later.

#### Trinity County.

G. W. Payne, manager of the dredger at Trinity Center, will soon start the season's run.

#### Tuolumne County.

The Mohican, near Tuolumne, has resumed operations after a shut-down of a month on account of lack of fuel. Extensive repairs were made and the mine and mill are now in first-class condition.—A company has been formed at Bangor, Me., to operate the Arrow mine, near Sonora, under the direction of G. Dean.—F. J. Gross has sold to W. R. Gillis of Tuttle town the New Year quartz claim, ½ mile north of Tuttle town.—Rich gravel has been struck in the Buckeye tunnel on Table Mt., at Mormon creek, near Tuttle town. The property is under bond from W. Stinchfield and is operated by T. A. Piper and associates.

#### Yuba County.

Drilling has been commenced at the Dunning ranch, near Marysville, by the Yuba Dam Gold Dredging Co. G. L. Proctor, of Rio Vista, has charge.

### COLORADO.

(Special Correspondence).—The U. S. Mint at Denver shows an increase of deposits over last year. The hullion is being held awaiting the completion of the coinage department. Since Jan. 1st this year there has been over \$8,000,000 in gold deposited at the mint. About 250

people will be employed at the new mint when they start coining.  
Denver, April 25.

#### Boulder County.

W. P. Marshall reports a rich strike in the Last Chance mine, in the Jamestown district. The property is owned by William Marr of North Park.

#### Clear Creek County

There are five sets of leasers working in the different veins recently opened in the Princess of India tunnel near Idaho Springs, which is being driven by Omaha capitalists. It is reported that the Torpedo tunnel on Springs gulch is to be started. This tunnel is owned by the Idaho Springs Gold Producing Co. and has been worked in a desultory manner the past winter. J. Hull of Idaho Springs is manager. The Torpedo tunnel is 1400 feet. The Lake mine in Virginia canyon is shipping ore to the Bonetta mill in Idaho Springs. The Roberts mill has put in a new 10x15 crusher.

#### El Paso County.

The Colorado City Oil & Gas Co. intends to sink a 3000-foot well near Colorado City to prospect for oil and gas. W. P. Epperson of Colorado City is manager.

#### Gilpin County.

A good strike is reported from the Boston lode on Stewart mountain, near Central City, by M. Kane, who has been driving a tunnel on this vein, which is now in 200 feet.

As a result of the experiments at the Petersen mill, in Lump Gulch, the Gold Dirt M. & M. Co., J. R. Anderson manager, is putting up a 50-ton plant in Gambell gulch, near Perigo. The mill is to be equipped with ten 1100-pound stamps and is expected to be finished by June 1. Sinking has been stopped in the Gold Dirt shaft for the present, at depth of 700 feet, and crosscutting to the south to cut the vein has been commenced. It is the intention of the company to convey the ores from their main property through the tunnel level, where an upraise is being made for a shaft, the ores to be hoisted through this shaft to the upper part of the mill. It is reported that the Perigo mill, in Gambell gulch, is to be started for a short run on Perigo ores. It is reported that the Blue Grass M. Co. will start work at Phoenix. The Mountain Monarch M. Co., in Gambell gulch, will extend their tunnel to the Seth Thomas vein. They may put up a 10-stamp mill. J. C. Barrows is manager. The Interstate Con. M. Co. has started work on their Happy Hollow group, near Gambell gulch. The new shaft is to be sunk 50 feet with windlass, after which the company intends to put in machinery for deeper operations. The Elk Park M. Co., west of Apex, will work the Annie H. under direction of Manager C. A. McNeil. The Imperial G. M. & M. Co., L. J. Mountz of Apex manager, will resume work on the Mackey mine.

#### Hinsdale County.

M. J. Elbert is working the Nelly Bly property, on the east side of the Lake Fork, near Lake City. G. H. Martin of the Hanna M. Co. has made arrangements with F. W. Sherman to remodel the mill at Capitol City. Manager Dryden has closed down the Pelican mine, near Lake City, during a trip to Boston, when he will arrange for an air compressor.

G. H. Martin, president of the Hanna M. Co., operating the Moro mine at Capitol City, contemplates remodeling the Hanna milling plant.

#### Lake County.

(Special Correspondence).—The smelter at Leadville was crippled for a few days on account of the weighing and wheeling gangs going out on a strike. It is understood that agitators have been at work in the district endeavoring to unionize the men. The new eight-hour law does not affect the men on strike and for this reason a strike was called to compel the smelter to grant them eight hours. The strike has been settled satisfactorily to all.

Leadville, April 25.

C. R. Osgood and associates of Leadville have a lease and option on the Ballard and President claims on Breece hill. The Ballard was the first mine in the camp in which hismith was found and for several months a streak 5 feet thick was mined and shipped to Europe. Both shafts will be sunk deeper in an effort to locate the ore channels. From the upper workings of both claims ore will be shipped that will more than meet the running expenses of the mine.

J. L. Craig of Twin Lakes has bought the holdings of the Mount Elbert Co., 2 miles from Twin Lakes.

#### La Plata County.

Rich discovery of gold is reported on the lower end of the Florida mesa, near Durango, on the ranch of H. N. Spinning.

#### Ouray County.

Work on the Blowout tunnel at Ouray is progressing at the rate of 2½ feet per day by hand work. The tunnel is 400 feet in length and 6x8½ feet cross section. It is proposed to put in power drills. Arps Bros. have acquired forty claims in Porphyry and Mineral basins, near Ouray, and have started work on a development tunnel which will be at least 4000 feet long. The purpose of running the tunnel is to cut a number of well-defined veins, among them being the Tomboy, Smuggler and other Marshall basin veins which apparently traverse this group. Where prospected on the surface the veins all show good gold and silver values.

#### San Juan County.

The Auburn Con. M. Co. on Tower mountain, near Middleton, has driven a 200-foot tunnel to cut the Auburn vein and intends to put in an 8-drill air compressor, drills and a new 80 H. P. hoiler.

A. J. Aurand is pushing work in the crosscut tunnel being driven to cut the Bullion King vein, Porphyry basin, near Silverton. The Shenandoah mine, King Solomon mountain, has commenced shipping copper-silver galena ore. Work is to be started on the Missouri Fred on the range between Boulder and Tower mountain.

The Gold Prince M. & M. Co. has made arrangements to build a 100-ton concentrating plant on the company's property in Mastodon gulch, above Animas Forks, 15 miles north of Silverton. A 2-mile tramway is to be built from the mine to the mill.

#### Sommit County.

The Union mill, near Breckenridge, has been completed. It is equipped with eight Wilfley tables, two Wilfley slimers, one crusher, two sets rolls, four Hartz jigs and three screens. Heavy machinery is being placed on the Reliance dredger, near Breckenridge, by E. Smith. The Summit county placer deposits occur in low flats and bars along the stream beds or in ridges or benches above the level, but adjacent to the streams, these latter being known as hench diggings. The beds are composed mainly of coarse gravel, some clay and a few large boulders. The gold is comparatively coarse, bright and clean.

#### Teller County.

(Special Correspondence).—The apex suit of the Morning Glory against the Mary McKinney has been compromised in the Cripple Creek district. It is understood that \$100,000 is the amount agreed upon.

#### Cripple Creek, April 25.

The jury in the Portland mining suit, in which James Doyle sought to recover \$1,000,000 which he alleged was due him for his interest in the Tidal Wave, Bobtail No. 2 and Devil's Own claims at Cripple Creek, now a part of the property of the Portland M. Co., have decided for the defendant. Suits for damages aggregating \$1,000,000 have been filed in the State and Federal Courts by the United States S. & R. Co. and a number of Cripple Creek mining companies against the Western Federation of Miners and its officers. The complaints are all of similar nature. They charge the defendants with unlawfully conspiring to injure the plaintiffs by preventing the mining and shipment of ore. The Vindicator G. M. Co. asks for \$20,000 damages for losses occasioned by the stoppage of its pumps. The suits are the outcome of the strike which was ordered in the Cripple Creek district on August 10, 1903, and has not been declared off, although all the mines are now operating with full forces.

Globe hill is to be worked through the Chicago and Cripple Creek tunnel by G. L. Keener. Operations on the Jo Dandy mine, at Cripple Creek, have completed additional ore house capacity and are now making a daily output of 100 tons. Manager G. D. Kilbourn of the Isabella Co. has men putting in machinery over the Empire State shaft at Cripple Creek and will start sinking the shaft another 500 feet. Bell and associates, operating on the Grace Arthur claim of the Jolly Jane Co. on Beacon hill, Cripple Creek, are driving a drift at a depth of 200 feet. A compressed air locomotive is to be put in at the El Paso Consolidated on Beacon hill, Cripple Creek, to haul cars on the third level. The shaft is almost to the 900-foot level, where laterals will be driven. The Longmont Leasing Co., in which Pullen and W. R. Foley of Cripple Creek are interested, are prospecting the bottom level, 350 feet, of the Sitting Bull on Bull hill, belonging to the Keystone M. & M. Co.

Hodges & Taubert have started work in the Ophelia tunnel to develop the Little Clara claim of the Work M. & M. Co., on Gold Hill. It is reported that Superintendent H. Starkweather of the Bayard Leasing Co., working the Trilby, Cripple Creek, has stopped development work and is cleaning up ore on hand, as the present lease expires May 1. A three weeks extension was given Harrison, Seaver & Co., lessees of the W. P. H. mine of the United Gold Mines Co., at Cripple Creek.

Austin and associates are drifting at the bottom level, 525 feet, of the Mary Alice, between the Portland and the Independence on Battle mountain. G. Wrockloff has leased a section of the Colorado Boss claim of the Cripple Creek Cons. Co., on Gold hill, and will put in an electric hoist. The Christmas shaft, on Bull hill, is to be sunk 200 feet deeper, giving a depth of 800 feet. A heavier hoisting plant will be put on by Lessee T. Vaine. It is reported that the Morning Glory Co. will sink the Aleen from the 250-foot level to the 650-foot point; and also drift at each 100-foot point.

R. L. Seaver intends sinking the 65-foot shaft of the Edith H., belonging to the Jean L. Co., on Beacon hill, to a depth of 150 feet. It is said that J. Wright, leasing the Hidden Treasure property of the Stratton Estate, will put in machinery and sink from the 400 to the 600-foot level. S. D. Crump, of Cripple Creek, has a three years lease on the Triumph on Battle mountain.

P. Penn and associates have an eighteen months lease on the Red Spruce property on Beacon hill. The new operators are required to do seventy-five shifts a month and to crosscut the property from the bottom of the shaft, which is at a depth of 375 feet. Lessees who have been working the Teutonic property on Iron-clad hill have resumed operations with two shifts on the sinking of the main shaft, which is down 305 feet will be continued to a depth of 350 feet before another station is cut.

The Work M. & M. Co.'s annual report for the year ending April, 1905, shows that the company shipped 1958 tons of ore, which gave an average value of \$34 to the ton. Of this amount the company received a total of \$12,146.48 in royalties. From Block G 150 tons were shipped and \$492.39 was the amount received as royalties. From Block D 1350 tons of ore were shipped, the company's royalties amounting to \$9959.33. From E, F and G blocks 243 tons of ore were shipped, netting the company \$821.37. From blocks H and J the royalties received amounted to \$833.39. During the twelve months 2500 feet of development work was accomplished. The lessees operating on this territory all pay 25% royalty, with the exception of those on the Little Clara claim. The gross receipts from all ore sent out by the lessees on this ground amounted to \$66,487.60. Of that amount \$36,477.47 was paid over to the lessees.

#### IDAHO.

##### Blaine County.

It is reported that the Sampson M. Co. will work in Sampson gulch, on Trail creek, 10 miles from Soldier, driving a tunnel 1200 feet to crosscut the three ledges at a depth of 600 to 1000 feet. F. R. Reed is manager. The Revis placer, on the Little Smoky, near Soldier, is being worked under direction of W. E. Pierce.

##### Boise County.

The Little Gem G. M. Co. of Pearl has put in a 25 H. P. hoist. J. C. Johnson is manager. C. E. Jackson, president of the Big Giant M. Co.'s

claims, 12 miles from Boise, says that tests will be made to determine the proper treatment for the ore, and a mill will be built.

#### Idaho County.

The Vendetta & Oro Grande M. Co. intends to build a 2½-mile flume from the south fork of Crooked river and put in a 400-ton crushing and cyanide plant at the Vendetta mine, near Oro Grande.

The Gott M. Co., near Resort, of which J. J. Toler is manager, are working Grouse Creek placers. J. W. Beckett and F. Clark of Spokane and S. Hilliard of Uniontown, Wash., have bonded a placer mine at Florence of W. Darrah, and will work it during the summer.

C. L. Hathaway, manager of the Portland & Idaho M. Co., reports that during the summer the company will operate a 50-foot Bucyrus dredge with a daily capacity of 300 cubic yards on Secesh creek, near Resort.

#### Owyhee County.

Track is to be relaid in the mill level tunnel at the De Lamar mine, at De Lamar. The upraise to connect the tunnel with the upper workings in the mines is to be made, and the ore brought to the mill through the tunnel. The gravity tramway will eventually be discarded. The Addie group on War Eagle mountain has increased its working force.

#### Shoshone County.

On Bear Top mountain, northeast of Wallace, on the north side of Pritchard creek, the Bear Top M. Co. has a mill completed, is building a flume to operate the mill by water power, and will soon be concentrating and shipping ore. The Great Western Co., at the junction of Military gulch with Canyon creek, 2 miles east of Burke, is running a crosscut tunnel to open their copper ledge.

Across Military gulch from the Great Western, the Reno group, located by T. Ryan and financed by W. R. Newport of Spokane, Wash., is being opened by a drift from a 300-foot crosscut tunnel. The company intends to start a second crosscut tunnel below the present workings. The Echo mine, between French and Hummel gulches, on Canyon creek, which has been idle for several months, has resumed work. At Mullan there are 325 men on the payroll at the Morning mine. At the Hunter there are at the mine and mill 100 men. At the upper workings of the Snowstorm 75 men are at work, and these, with the employees at the lower workings, make 100 in all. The Silver Cliff employs 6, Snowshoe 4, Gullen and San Quentin 4, Copper King 4, and the Idaho Giant 4 men. The Montana Standard M. Co. of Burke will run a 1200-foot tunnel to tap the lead. A flume is to be built to convey water for power for a new compressor to be put in.

#### Washington County.

The Ford mill at Black lake is reported to have been closed temporarily because of breakage of crusher caused by a sledge hammer in the ore.

#### MICHIGAN.

(Special Correspondence).—Work has been started on the Keweenaw Central Railway from Calumet to Lac La Belle, in Keweenaw county. F. L. Van Orden, superintendent of the Wyandot Copper Co., and W. R. Wallace are exploring with diamond drill near the Bohemian Range M. Co.'s property in Keweenaw county. Repairs to the Osceola Con. M. Co.'s stamp mill on Torch lake are progressing rapidly. At the Tamarack Co.'s stamp mill the remodeling of one simple stamp has been completed. After remaining idle for two weeks, the trammers and other underground employees at the Wolverine mine have returned to work. There were only 100 men out on strike, but they prevented 300 other employees from working. Inasmuch as the strikers at the Wolverine, Franklin, Osceola, Quincy and Franklin Junior mines were forced to return to work without their demands being granted, it is believed there will be an early settlement of the trouble at the North and South Kearsarge branches of the Osceola Con. Co. Improved results are being secured by the Isle Royale Con. Co. Rock shipments average 600 tons daily. The opening of a permanent shaft on Section 11 and exploration of the southern end of the property with the diamond drill will be pushed.

Calumet, April 22.

#### MISSOURI.

##### Jasper County.

(Special Correspondence).—The Hancock M. Co.'s new electric mill on the Murphy land, near Joplin, is enclosed and will be started soon. The Lillie M. Co., on the Amazon land at Sherwood, owned by C. M. Wilson, has contracted for a new 100-ton mill. The company has two shafts in ore. Basha, Starr & Meese of Joplin have opened up a good prospect near Four Corners. Brooks & Co., on the Panama lease in the Chitwood district, are sinking another shaft 800 feet south of the prospect and have found lead and jack at a depth of 36 feet. A company composed of Mrs. J. J. Funk of Webb City, Brogg, Brookshire & Murphy of Duenweg and J. W. Walker of Joplin has opened up a prospect on the Kirk land, 1½ mile south of Duenweg. A shaft has been sunk 76 feet. The company has put in hand jigs for cleaning the ore. The Fort Scott M. Co. is sinking a shaft on the Highball lease at Duenweg. T. N. Cheneweth of Joplin and E. J. Messall, J. H. Cline and J. H. McCue, all of Concordia, Kan., will move the Olympia No. 1 mill to Chitwood, and expect to have it running in a few weeks. They have formed the La Grande M. Co.

Joplin, April 24.

The Cold Day M. Co. has struck lead at 90 feet on the Regan land, near Joplin. The Searcher D. Co. is drilling on the Cunningham land near Myrick station, between Galena and Joplin. The Tin Button M. Co. has struck a good prospect on the Regan land. They are cribbing the shaft and preparing to run a drift. The Sexton mine, owned by the Empire M. Co., in Joplin, is sinking a new shaft to open up ore. N. P. Rood and R. Root, of Joplin, and J. Montgomery and P. H. Puckett, of Galena, owners of the Deborah M. mine in West Hollow, have put in a 10-inch lift pump.

#### Lawrence County.

A new derrick is being built at the shaft being put down on the Federal land by Superintendent G. Stratton of Aurora.

## MONTANA.

## Fergus County.

G. Bollis of Malden has sold to A. P. Morgan of New York City the Bells group, near Malden, together with the Marshall tunnel and tunnel site. It is understood that the buyer will organize a company to develop the property.

## Silver Bow County.

(Special Correspondence).—The decision of the Supreme Court awarding the Minnie Healey mine to F. A. Heinze does not alter the position of the Amalgamated C. Co. and Mr. Heinze, parties to the eight-year mining litigation in which more than 100 suits are now pending. Mr. Heinze has been in possession of the Minnie Healey and has been working it ever since the litigation over that property was begun. The case did not involve any of the numerous disputes over ore bodies, extralateral rights, or the application of mining laws. The only question involved in the Minnie Healey case was whether or not Miles Finlen, the predecessor in interest of the Amalgamated Co., agreed to sell his interest in the property to Mr. Heinze and actually placed the latter in possession of the mine before he changed his mind and sold out to the Boston & Montana Co., an Amalgamated corporation. Two district courts and the Supreme Court have found that Finlen did dispose of his interests to Heinze and had nothing left to sell to the Boston & Montana Co. The shaft of the Belmont mine, being developed by the Belmont M. Co., a United copper concern, has reached a depth of nearly 1000 feet, but no ore has yet been found, although several crosscuts have been made from various levels. The Belmont has no apex vein, but it is known that there are rich ore bodies in the ground and that some other companies, owning adjoining claims, are working on them. About 500 tons of ore a day are being mined from the Corra mine by the Corra-Rock Island Co. A new hoisting plant is being put up, the foundation for which has been completed. As soon as the new engine is put in the old one will be moved to the Lexington mine which F. A. Heinze is to explore and develop. The Butte Copper & Zinc Co., which purchased the Emma mine, has drawn plans for a concentrator to be built in South Butte for the treatment of the silver-zinc ores of the Emma. The Columbia and Emmerson gold mines in the Lowland district have been handed to John Ray of Butte for \$65,000, the bond to run for one year.

Butte, April 25.

## NEVADA.

The Nevada Legislature has passed a bill, making it unlawful for any person, company or corporation after July 1, 1905, to sink or work through any vertical shaft at a greater depth than 450 feet unless the shaft is provided with an iron-hoist safety cage, to be used in the lowering and hoisting of the employees; also any shaft less than 450 feet deep, where no safety cage is used, and where a cross head or cross heads are used, platforms for employees to ride upon while coming up or going down the shaft shall be placed above the cross heads. The provisions of the act require the placing of these platforms on the cross heads not later than July 1, 1905.

The Bullfrog Miner, of Beatty, regarding the mines of this district, says that Montgomery-Shoshone mine, M. Hoveck, superintendent, employs fourteen men; shipping rich ore. Original Bullfrog, G. Perce, superintendent, employs fourteen men; sacking good ore. National Bank, W. Smith, superintendent, employs thirteen men. Bullfrog M. Co., Ladd & Benson; J. Simpson, superintendent, employs twelve men. The Denver, O. B. Kemp, superintendent, employs four men. McCalliard & Dyer, on Denver lease, have three men sacking ore. Eclipse mine, on Denver mountain, R. Sutherland, manager, employs five men on shaft and surface work. Montana Bullfrog, on west slope of Ladd mountain, M. Walsh, superintendent, employs six men. The Yankee Girl, J. Robinson, superintendent, employs four men doing development work on flat to catch Ladd mountain ledge. Colorado Bullfrog, T. Kilker, superintendent, employs four men doing development work on flat near Ladd mountain. The Hazeltine or Gold Bar, Mr. Reinhart, superintendent, employs six men on development work. Bullfrog Extension, near Original Bullfrog, T. C. Tridel, superintendent, employs four men. The Bullfrog Annex, Montgomery Mountain M. Co., and Amethyst employ small forces. Tramps mine, on Denver hill, M. Whitelaw, superintendent, employs four men. Amargosa M. Co., Mr. Gracey, superintendent, employs four men sinking shaft on flat south of Ladd mountain; will put in gasoline hoist. Big Bullfrog, near the Original, T. McCahe, superintendent, employs four men sinking shaft. The Bullfrog Winner, near Hazeltine, J. Meighan, superintendent, employs three men. Lumber is \$130 per 1000, wood \$30 per cord, coal \$80 per ton, hay \$90 per ton, flour \$7.50 per cwt., eggs 60c per dozen, bacon 25c, ham 25c, good steak 30c per pound, potatoes 8c per pound, butter 40c per pound, sugar eight pounds for \$1, tea per pound 60c, coffee per pound 40c, meals 75c, heds \$1 per night, beer per bottle 75c, whiskey or beer per drink 15c, saddle horse per day \$4, shave 25c, hair cut 50c, freight per pound from railroad 3 to 4 cents per pound.

## Lincoln County.

O. B. Landon and A. B. Day have sold their holdings in the Searchlight M. & M. Co. to H. E. Carter and Mr. Lichtenberger. G. I. Meyers is manager at Searchlight. A 15 H. P. gasoline hoist and a roller mill are to be put in. The main shaft is to be deepened. At the Cyrus Noble cyanide plant the filtering by vacuum process has not been a success on account of the large quantity of slimes. Two settling tanks are being set up and in future the decantation process will be used. The plant is experimental and has a capacity of fifteen tons a day.

Searchlight is 10 miles east of the California line and 14 miles from the Colorado river. The companies now operating in Searchlight are: Quartette M. Co., Duplex M. Co., Good Hope M. Co., Searchlight M. & M. Co., Southern Nevada M. Co., Pompeii M. & M. Co., Boulder M. & M. Co., Saturn M. Co., Mondamon M. Co., Peerless M. Co., Enterprise M. Co., Cyrus Noble M. Co. and Santa Fe M. Co. The Quartette is operating a 20-stamp mill continuously. F. J. Harrington is superintendent.

The Duplex and Good Hope properties are operated by F. Colton and A. L. Glassell. The Searchlight M. & M. Co., of which G. Meyers is president, is taking out \$15,000 per month hullion. The Boulder M. & M. Co. is sinking entirely through the wash on the flat at the foot of the range. They have struck some very high values and at 120 feet have opened up two ore bodies. There are now in the district one 20-stamp and three 10-stamp mills, all of which are operating continuously.

Callente reports say that the Twin Pines group, south of the Virgin river, has been sold by Morris & Henley to McCulloch, Rice & Borden of Kansas City, Mo., who intend to build a mill.

## Nye County.

The Boston-Tonopah M. Co. has started work at Tonopah. J. F. McCambridge is superintendent.

In a recent report of the U. S. Geological Survey, J. E. Spurr says that the general conditions for mining and profitable production of ores at Tonopah are decidedly better than they were a year ago. The greatest advance has been in the building of a railroad to Tonopah, connecting with the Carson & Colorado Railroad at Rhodes, near Sodaville. This has lessened the cost of transportation, so that supplies have become cheaper and ores can be profitably marketed which are of lower grade than what was regarded as "shipping" ore during the period when a 60-mile haul in wagons was necessary. The roads are inadequate, however, for the needs of the district. The supply of water for the town seems to be somewhat more abundant than last year, though there is still much to be desired. Part of the supply still comes from the wells of the Crystal Water Co., 4 miles north of the town, while another portion is derived from the Rescue shaft, within the town. Until recently there have been only three principal producing mines in the Tonopah district, although a number of others have shipped small quantities of ore. These producers have been the consolidated Mizpah and Valley View mines (Tonopah M. Co.), the Montana Tonopah, near by, and the Belmont Co., whose properties are operated through the Desert Queen shaft. Recently, however, the Tonopah Extension has been discovered and developed, and from this new mine shipments of considerable amounts of ore have already been made. The success of Tonopah brought to the region an army of prospectors, who have been searching the desert for other ore deposits. The most notable result of this prospecting is seen in the new camp of Goldfield, 28 miles south of Tonopah. Already this camp equals or exceeds in population and far exceeds in activity the parent camp of Tonopah. The prediction made in Mr. Spurr's report of last year that new veins belonging to the productive period of the earlier andesite would probably be discovered underneath the later overlying lavas has been fulfilled during the past year by the discovery of several such veins. Large bodies of rhyolite dacite have also been encountered which frequently contain quartz veins. On account of the resemblance of these veins to those in the earlier andesite veins, they have been the object of a good deal of exploration and development work, whose average results have been unprofitable. The productive area has been slightly enlarged. The complicated faulting, characteristic of the district, has entailed serious hindrance to mining operations.

## White Pine County.

A. Jackson, superintendent of the Rocco-Homestake mine, near Hamilton, reports that they are sinking a winze off the shaft level to strike the lead vein. E. L. Whittle has been examining the Ne Plus Ultra mine, near Hamilton, in the interest of W. C. Rose. It is reported that J. Fairvina has struck good ore in the Julia mine on Treasure hill. A. Muir and W. Read are working the Protection mine, south of the Homestake.

## NEW MEXICO.

## Doña Ana County.

The Stephenson-Bennett Con. M. Co. of Las Cruces has resumed work on the new shaft which is to be sunk 700 feet. W. N. Crummer of Spokane, Wash., is the superintendent. The company intends to build a tramway from Organ to the El Paso smelter. N. Rose is developing the Mormon in Gold Camp. C. Anthony is opening up copper ore on the Memphis at Organ.

## Grant County.

At Santa Rita, C. P. Crawford will build a concentrating plant to treat low grade ore, the result of last year's work in Chino Canyon. The Comanche M. Co. will make improvements to its 150-ton smelter at Silver City this summer. A new 250-ton furnace has been ordered and a new 200 H. P. engine will be installed. A steel building will be built to cover the furnace plant.

## OREGON.

The Oregon Legislature has passed a bill remitting the law fixing an arbitrary license of \$10 a year on all companies owning properties that have not produced \$1000 in the preceding year. The bill providing that the date of manufacture of blasting explosives be labeled on the original package has gone into effect. Such a measure as this has never been tried in Oregon, but similar ones have been enforced by other mining States, and miners assert that they add materially to the safety of workmen underground. Mining companies may be organized in Oregon and have a board of directors resident elsewhere.

## Baker County.

Geo. Fry, manager of the Chicken Creek diggings, Weatherly, is ready for another season's run. M. Vohrer is working in Quartz and Hogback gulches, near Weatherly. M. N. Thompson, manager of the Granite mountain, near Weatherly, is crosscutting Granite mountain, and has driven 200 feet since January. F. Canaday of Warren, Ind., has arranged for the resumption of work on the Independent property adjoining the Granite mountain. W. A. Thompson, superintendent of the Indiana & Oregon G. M. & M. Co., of Covington, Ind., has received instructions through S. O. Trescott, the general manager, at Richmond, Ind., to begin work at the Gold Cliff, near Weatherly.

## Grant County.

Manager Gulgan of the Alamo group, at Alamo, is expected to commence operations on the mine. It is re-

ported work will be started on the Oro Fino group, at Alamo.

## Jackson County.

The Blue Jay mine and 10-stamp quartz mill, near Coles, has been sold to Los Angeles parties, who will operate it. Five stamps are crushing eight tons of ore daily at the Homestake mine, in Evans Creek district, near Woodville, and five more will be added to the mill. An air compressor is to be put in. F. Trowbridge has charge. Foster & Gunell of Grants Pass, operating the Oregon Belle mine, near Jacksonville, will place a 10-stamp quartz mill on the property to replace the small Huntington mill.

A \$3700 gold brick is result of a recent run at the Sturgis mine, of Forest Creek, 6 miles from Medford. The Sturgis is worked by L. A. Vanco and associates of Los Angeles. W. E. Olmstead has charge.

## Josephine County.

(Special Correspondence).—Manager J. R. Harvey is cleaning up at the Royal diggings, after the first half of the season's run. Only one giant was used. Supplies have been hauled to the Golden Eagle. Twelve miners will work during the summer months. Galice, April 24.

Superintendent L. B. Wickersham has returned to the Granite Hill mine, in Louse Creek district, near Grants Pass. Five machine drills are in the workings of the Granite Hill and one is being run in Red Jacket. The mill's ten stamps are dropping constantly.

## Lane County.

(Special Correspondence).—At Blue River, the Great Northern stamp mill has resumed. An aerial tramway will be erected this summer. The Lucky Boy 40-stamp mill will be started next month. Mr. Parks of the Treasure has ordered a 12-stamp mill. Bohemia, April 26.

C. C. Mathews, superintendent of the Oregon Securities M. Co. at Bohemia, reports that the Oregon Securities mill is dropping twenty stamps and that the full thirty will be started soon.

## Marion County.

(Special Correspondence).—In the Santiam district, there are six incorporated companies. The first mill will be built this summer. Santiam, April 25.

## SOUTH DAKOTA.

## Lawrence County.

The Imperial G. M. & M. Co. is building an addition to its tank room at its cyanide plant in Deadwood, by which it is proposed to increase the capacity to 150 tons daily. The present steam equipment is to be replaced with electric motors.

## Pennington County.

(Special Correspondence).—The Extreme M. Co., 3 miles northwest of Custer, contemplates extensive improvements the coming summer, including an addition to the mill and a cyanide plant. The ore is quartz, with mispickel and pyrite. The process is essentially one of amalgamation, concentration and cyanidation, the latter probably the bromo-cyanide process. The concentrates contain about 25% arsenic, which, as yet, they have not attempted to treat. Custer, April 20.

## UTAH.

## Plute County.

Treasurer A. A. Ball of the Annie Laurie M. Co. of the Gold Mountain district, Kimberly, reports that the new No. 5 tunnel will go into commission May 1. Manager Levy has men timbering the raise connecting with the tunnel above. As soon as the timbering is finished the new adit will be ready for use.

## Salt Lake County.

At Bingham another shift has been added at the Teck tunnel, which is in 350 feet. A flow of water has been encountered amounting to eighty gallons per minute, and at present the face is in soft ground, which necessitates timbering, but this is not expected to continue far. Manager W. C. Orem of the Utah-Apex M. Co. of Bingham has ordered a 4-drill air compressor. The adit, when completed, will be 3000 feet in length and will tap the ore bodies on the dip at a depth of 2500 feet from the surface and will open reserves 500 feet below the present lowest workings, vertical depth. The tunnel will be 7 feet high and 6 feet wide in the clear and will allow the laying of a double track. Eventually this new tunnel will be the main avenue for the exit of all ores from the mine. The upper levels will be connected with it and ore from them will be dropped into chutes, from which it will be loaded automatically in mine cars and thence taken out to the mouth of the tunnel, where it will be taken up and conveyed to the smelters over the Copper Belt tracks.

Manager W. G. Craig of the Kennebec mines, Alta, has decided to drive an intermediate tunnel 400 feet long midway between the upper and lower one. With this he will connect with the lode at a station 50 feet below the old stopes. An electric generator is to be put in and run with water from the tunnel.

## Utah County.

The Signet M. Co., in American Fork canyon, has resumed operations. It is reported that the Hot Stuff, owned and operated by the Goodsell M. Co., will be started. C. D. Hanks of American Fork is working the Wish Bone mine, near the Dutchman mine; the Geneva and May Blossom, near the Silver lake at the head of Deer creek; the Boley mine, on Millar hill, and the old Waterfall, in the head of the canyon.

Woodward Bros., who are working the Buckley mine in Rock canyon, near Provo, on a lease, have shipped two carloads to the smelter at Murray. This will be the first ore shipped from the Provo district.

## WASHINGTON.

## Ferry County.

C. E. Hoffman, manager of the Globe G. & C. M. Co., has resumed work on the company's property on Toulou mountain, 3 miles southeast of Orient. The tunnel, which is now in 136 feet, will be driven ahead to tap the ledge.

## FOREIGN.

## AFRICA.

Success is attending the prospecting of the Lower Witwatersrand reefs, near Roodpoort, and near Rhenosterspruit in the Klerksdorp district. There is marked activity in connection with the older reefs, especially in the Heidelberg district and in the Western Rand, and the experience gained in a good many instances seems to show that the reefs improve in depth. Their gold contents are not as consistent as those of the Main Reef series—the country is more broken and irregular, and mining may be expected to be somewhat costly—but with all the Main Reef ground taken up at a reasonable depth capitalists are finding it advisable to bestow some attention on these lower series of reefs, now proved to extend over many miles north of the outcropping Main Reef series. Columbus country, between Johannesburg and Pretoria, has been shown to possess these lower reefs, but their value proved so far seems to be too low to admit of successful working.

Two thousand Chinamen employed at the North Randfontein mine, near Krugersdorp, recently struck, expressing dissatisfaction with their wages. The trouble was caused by their refusing to drill more than 12 inches per day, and then stopping work until they came to the surface. Other coolies who drilled more were intimidated and ill treated by members of a Chinese secret society. The Chinese have now resumed work and are drilling satisfactorily. They have informed the gangers that they now intend drilling 3 feet.

## CANADA.

## BRITISH COLUMBIA.

## Boundary District.

Boundary ore shipments for week ending April 22 were as follows, each district smelter having some furnaces out of commission for repairs. Granby mines to Granby smelter, 9850 tons; Mother Lode to British Columbia copper smelter, 3500 tons; Brooklyn to Montreal & Boston smelter, 315 tons; Rawhide to Montreal & Boston smelter, 180 tons; Mountain Rose to British Columbia copper smelter, 231 tons; Dominion C. Co.'s Stemwinder dump to Trail smelter, 70 tons; Oro Denoro to Granby smelter, 70 tons. Total for week, 17,051 tons. Total for year, 284,164 tons. The treatment by the Boundary smelters for the past week was as follows: Granby smelter, 12,018 tons; British Columbia copper smelter, 3818 tons; Montreal & Boston smelter, 3350 tons. Total for week, 19,166 tons. Total for year to date, 290,807 tons.

At Skylark the Tip Top has been bonded for W. S. Macy of Phoenix by R. Stuart and J. C. Haas of Greenwood.

## Nelson District.

It is announced from Nelson that the amalgamation of the LeRoi, War Eagle, Center Star and Snow Shoe mines and Trail smelters has been completed. The new company has a capitalization of \$10,500,000.

## Rossland District.

It is reported that the Cliff mine near Rossland is to be started under the direction of C. E. Simpson.—The shipments for the week ending April 22 were: Le Roi, 2525 tons; Center Star, 2080 tons; War Eagle, 1170 tons; Le Roi No. 2, 150 tons; Jumbo, 200 tons; Spitsee, 270 tons. Total for week, 6395 tons, and for the year, 108,952 tons.

## Slocan District.

B. P. Little, lessee of the Payne concentrator, is turning out some high-grade zinc and almost pure iron ore from the magnetic separator.—G. F. Ranson, manager of the Payne, will start up to the Sovereign mine.

## Vancouver Island.

The British Columbia Mining Record says the great coal measures of Vancouver Island extend from Ladysmith north to Union, 75 miles. The Extension mines, 11 miles from Ladysmith, from which high grade coal for domestic purposes on the Pacific coast is shipped, are known by borings and prospecting to extend nearly to Ladysmith. The coal shipped from the island to date amounts to 19,940,587 tons, with a value of \$60,203,285, and the coke to 149,556 tons, with a value of \$947,780; a total of \$61,151,065. On the west coast of the island, beginning at East Sooke, mineral has been found and small shipments made from San Juan, Port Renfrew, Alhemi, Uchucklesit, Clayoquot, Kennedy Lake, Taferno Inlet (Deer Creek), Bedwell Sound (Bear River), Trout River, Clayoquot Sound, Sidney Inlet, Ahousat, Ahat-lasett, Nootka, Kyuquot and Quatsino, while in the middle of the island at Central Lake a large deposit of mineral has recently been discovered. The schist beds lying to the south of the coal measures, known as the Mt. Sicker schist belt, extend from Mt. Sicker up to the Nanaimo lakes. These have been opened and worked along 40 miles at Mt. Sicker, Mt. Brenton, Chemainus, Majuba, Rhinehardt, Nanaimo lakes and Englishman's river. Owing to the fact that the land is heavily timbered, prospecting is slow and expensive. The total quantity and value of the metallic mineral product to date of Vancouver Island and vicinity is given by the Provincial Mineralogist, W. F. Robertson, as 275,322 tons, of a value of \$4,378,370.

## Yale District.

Greenwood reports says F. L. Underwood of New York, president of the British Columbia Copper Co., and W. H. Thomas, consulting engineer, are on a trip through the Kettle river and the Similkameen districts, accompanied by W. N. Merrill and J. Killer Schon of Duluth, to find the facts of the proposed smelter at Midway and the probable tonnage which could be secured from these localities.

## MEXICO.

Mining men of Mexico are interested in the situation which has resulted from the destruction of part of the plant of the National Dynamite & Explosives Co. in the State of Durango. This company was recently given a monopoly of the Mexican field by the government placing in effect a high tariff on the importation and consumption of foreign dynamite. The explosions wrecked the mixing departments of the plant, completely shutting off the output and making it a matter of months

before dynamite can be again manufactured. The company claims to have on hand supplies sufficient for the Mexican demand for three months, but it will be impossible to repair the damage and install new machinery within that period. It is evident that foreign dynamite will have to be imported, and the concessions held by the company gives it the right to bring in dynamite from abroad at one-seventh of the prevailing tariff. French dynamite companies are principally interested in the Mexican company, and any importations made by that concern will be undoubtedly made from France.

## Durango.

It is reported that the American-Mexico M. & Dev. Co. has blown in its lead smelter at its property near San Lorenzo. The company's pyritic plant was blown in the last of March and is now in successful operation. The capacity of the latter is 60 tons, and that of the former 100 tons, with arrangements for increasing to 500 tons.

## Sonora.

(Special Correspondence).—At the Hidalgo mine at Nacozari men are sinking a shaft and running a tunnel. This property is owned by the Hidalgo M. Co. and is being worked under bond by A. Adamson.

Nacozari, April 24.

(Special Correspondence).—The Calumet & Sonora M. Co., which owns the San Antonio, San Juan and Buena Vista mines, 5 miles south of Cananea, has purchased \$60,000 worth of machinery. Superintendent A. C. Daugherty states that development work will be pushed rapidly.—J. B. Tomlinson, general manager of the Swansea mine, near Cananea, says that his company is putting in additional machinery as rapidly as weather will permit. A new vein of malachite ore running high grade copper and silver has been found.—F. L. Proctor, G. McMillan and D. McMillan have sold the Dos Naciones mines, adjoining the Cobre Grande mine near Cananea, to Duluth, Minn., parties.—J. W. Hardy has sold his copper property, 6 miles from Cananea, to Northern capitalists, who will begin active operations at once.—P. E. Murray, superintendent of the Lindsay Cananea Central M. Co., reports good progress.

Cananea, April 24.

The Sandoval concession of the Boludo gold placer mines, 2½ miles northwest of El Tiro, in Altar district, has been taken over by L. Lindsay of Los Angeles, Cal. Crushers and rolls are to be put in and water is to be brought to the ground.

## SOUTH AMERICA.

## Bolivia.

W. Hooker, in the Mining Journal, says that, in addition to gold, silver, copper and tin, bismuth, mercury, platinum, lead, iron, zinc, nickel, aluminum and sulphur are found in Bolivia. Coal has also been discovered near Lake Titicaca. Most of the metalliferous deposits exist on the eastern slopes of the Andes, at considerable heights above sea level, and their nature of occurrence generally renders it most convenient to work them by adit. But, notwithstanding that mining is traditional throughout the country, practice is crude to a degree and what is even a greater drawback—the country is so entirely without means of communication that each district is practically self-dependent, and economical co-operation between the agricultural and mining communities is impossible. On the southwest a highly mountainous tract, commencing with the district of Potosi, which adjoins the Chilean boundary, terminates northward 120 miles beyond La Paz. The only railway runs in from Antofagasta, through Uyuni, and terminates at Oruro. It enables the nitrate and borax deposits to be worked cheaply and serves one or two mines. The Huanchaca mines built their own branch line on to the main track. The Colquechaca mine, five days' march from the railroad, has a plant including two Cornish pumps and two tubular boilers. Hoisting is done with a steam capstan. The heavier machinery was taken up in parts over a specially constructed cart track, but most of the material goes up on the backs of mules. Their old reduction works was 10 miles down the valley at La Palca, and the ore was carried down by llamas and mules. Now they have a reduction plant close to the mine, and the concentrates are frequently sent down to the coast for shipment. The works at La Palca have been taken over by an American firm, who work a lixiviation plant, purchasing the ores from the different mines. At Colquechaca there would be sufficient water power for a proper electrical installation by water wheel. At the present time they are pumping up hundreds of gallons of water per hour, while there are two small streams running on each side of the property. There are at present some twenty-four tin mines in operation, all worked in a very crude manner, besides innumerable stream workings. The ore, which is cassiterite, is picked, crushed, concentrated and shipped. Hand picking is done on a large scale and frequently the stone is practically pure tin. A mine in Llallagua, belonging to Don Pastor Sainz, is on the slope of a mountain, 4700 meters above the sea level. The vein is close to the face of the mountain, and to reach it they drive in adits. The concentrated ore goes 62% tin, and the loss in tailings is from 10% to 12%. Between Colquechaca and Sucre there is much tin washing done in the rivers and large quantities of tin are produced.

## Obituary.

RICHARD MURLEY, an old-time miner of Gilpin county, Colo., died at Edgewater, near Denver, April 21, of miner's consumption.

J. E. KEARNS, one of the pioneers of Kawich, Nev., and owner of fifty-four claims in that district, died April 17 in Kawich of pneumonia.

W. G. TIFFANY died April 23 in New York City. Tiffany was 63 years old. Most of his business life was spent in the West and Southwest, where he was engaged in many mining ventures.

## Personal.

F. E. WADE is manager Glohe M. Co. of Deadwood, S. D.

D. C. TOBIN is superintendent Continental mines at Vulcan, Colo.

J. M. BURKE has returned to Spokane, Wash., from a visit to Utah.

P. BEARDSLEY of Chicago, Ill., is mining at Tanticaro, Michoacan, Mexico.

JOHN GRAY, manager Wasp No. 2 M. Co., has returned to Deadwood, S. D.

J. H. EMERY, manager Gold Coin M. Co., has returned to Idaho City, Idaho.

L. LANE is superintendent Victor & Virgin mine, near Vivian, Mohave county, Ariz.

G. A. WRIGHT will take the management Totok mines, Celebes, Dutch East India.

J. D. SPARGO has resigned as superintendent Gold Road M. Co., near Vivian, Ariz.

A. M. ROCKWELL has resigned as superintendent White G. M. Co. at Tucson, Ariz.

W. J. KEOUGH has been appointed superintendent Minerva M. Co. at Atlanta, Idaho.

J. E. NIHILL, superintendent Mayflower mine, Forest Hill, Cal., has been in San Francisco.

F. H. NETTLETON of Spokane, Wash., has been examining mines in Mohave county, Ariz.

E. E. RODGERS, president Black Pearl M. Co., has returned to Pearl, Idaho, from Chicago, Ill.

E. F. SPARROW has succeeded E. I. Leach as superintendent Gold Treasure M. Co. at Naco, Ariz.

M. J. MAHER, president Montana Standard M. Co., has left Burke, Idaho, for a short Eastern trip.

T. G. DAVEY, consulting engineer to the Northern Copper Co., has returned to Rhodesia from London.

T. MANION of Ouray, Colo., has been appointed superintendent Flying Dutchman M. Co. at Eureka, Utah.

L. W. TRUMBULL has taken position as consulting engineer with Strong Copper M. Co. of Leslie, Wyo.

J. C. BARROWS of Centerville, Iowa, is manager Mountain Monarch M. Co. at Rollinsville, Gilpin county, Colo.

E. GUARINI of Brussels, Belgium, has been appointed to a professorship in the school of engineering at Lima, Peru.

W. A. HOLT AND A. C. SEIBOTH of Globe, Ariz., are at Superior, Mich., inspecting the Lake Superior & Arizona mine.

C. GREEN, president Idaho Placer M. Co., near Olds Ferry, Washington county, Idaho, has returned from a trip East.

M. BROWNING, formerly superintendent Enterprise mine at Slocan, B.C., is now superintendent Rustler M. Co., Libby, Mont.

E. F. GORDON, general manager Hillside M. & M. Co., has been at the company's mines at Big Creek and Orgrande, Idaho.

T. E. LUDLAM of Sea Isle, N. J., president Union Pass G. M. Co., has been examining the company's mines near Kingman, Ariz.

F. W. HOAR, of El Paso, Texas, has succeeded J. H. Knowles as superintendent Chiricahua Development Co., at Paradise, Arizona.

M. BOUERY will be retained as manager La Grange mine on Oregon Gulch mountain, 6 miles west of Weaverville, Trinity county, Cal.

C. W. WILLIAMS has been appointed superintendent Mountain Iron and Stevens mines of the Oliver M. Co. at Mountain Iron, Duluth, Mich.

P. T. BAIRD has resigned as superintendent Hidden Treasure G. M. Co., at Lead City, S. D., to take the superintendency of Big Four M. Co., at Lead City.

A. E. DRUCKER, E. M., has taken a position with the Oriental M. Co. in Korea, as superintendent of their cyanide department, and leaves San Francisco, Cal., for his field of duty May 12.

## Books Received.

"Proceedings of the American Institute of Electrical Engineers," 95 Liberty street, New York City.

"Underground Waters of Eastern United States," by M. L. Fuller, Bulletin 114 of "Water Supply and Irrigation Papers" of the United States Geological Survey.

"Martin's Mining Cases of British Columbia," Vol. II, Part I, has been issued from the press. The rapid development of the mineral resources of British Columbia the past few years has resulted in a largely increased population in that province, and incidentally a great deal of mining litigation, and court decisions on the legislative acts of the Dominion Parliament. The author has collected the numerous reports and decisions which heretofore have been scattered through numerous volumes of legal matter, and has embodied these in compact volumes, and including numerous unreported cases, so that these books, Vol. I and Vol. II, now form the beginning of a series of statutes and valuable decisions on the mining law of British Columbia. These volumes bring the subject down to Jan. 1, 1905. It is the intention to issue these "Mining Cases" regularly, and they cannot fail to be of great value to practicing attorneys and to mine managers in that province. A notable feature of these cases is the head and foot notes prepared by the author, Mr. Justice Martin. These are written with unmistakable completeness and clearness. All who in any way come in contact with mining legislation in

British Columbia will find "Martin's Mining Cases" of great value. The book is published by The Carswell Co., Ltd., Toronto, Ontario, Canada, for \$5, and will be sent postpaid by the MINING AND SCIENTIFIC PRESS upon receipt of price.

## Trade Treatises.

The Foss Gas Engine Co., Springfield, Ohio, catalogue portrays a portable engine with steel truck.

The No. 15 Keller assay balance is finely portrayed in a series of slips sent out by the manufacturers, the Salt Lake Hardware Co., Salt Lake City, Utah.

A 138-page catalogue from the Rawson & Morrison Mfg. Co., 31 Main St., Cambridgeport, Mass., describes their bolting and automatic coal handling machinery.

"Crushing Rolls" for wet or dry crushing is the title of a handsome 12-page pamphlet illustrating and describing the crushing rolls manufactured by the Fulton Iron Works, San Francisco, Cal.

The second edition of Catalogue No. 6-B, "Stamp Milling Machinery," from the Colorado Iron Works Co., Denver, Colo., has considerable illustrated description of modern appliances in stamp milling and ore reduction plants of manifest interest.

The most pretentious publication of the kind received this week is the 250-page quarto, substantially bound, entitled "Stirling: a Book on Steam for Engineers," and which goes into the entire subject in all its details in an elaborate manner. There are several formulae of technical value and the work is worth examination by any one having to do in any capacity with the operation of a steam boiler. It is from the Stirling Boiler Co., Pullman Bldg., Chicago, Ill.

## Commercial Paragraphs.

THE S. H. Supply Co. of Denver, Colo., are furnishing a 15-drill compressor plant for shipment to Mexico, a 5-stamp mill to Hailey, Idaho, and a 10-stamp mill to California.

THE Fulton Iron Works, San Francisco, Cal., have closed a contract with the Sierra Buttes mines, Cal., W. D. Pinkston, superintendent, for furnishing them a complete 40-stamp mill to be driven by water power, and a complete cyanide plant having twelve 30-foot diameter by 6-foot deep leaching tanks with all accessories for both mill and cyanide plant.

THE Brown Corliss Engine Co. of Corliss, Wis., have an order from the National Tube Co. to furnish the McKeesport plant with two 38-inch & 70x60-inch tandem compound rolling mill engines for special heavy work. They have shipped a 32-inch & 60x48-inch combined vertical and horizontal condensing engine for the Illinois Steel Co. Joliet plant.

THE Compressed Air Machinery Co. of San Francisco, manufacturers of the Word Bros.' drill maker and sharpener, have shipped three machines to the Oliver Iron Mining Co., Duluth, Minn.; one to the Cleveland Cliffs Iron Co., Ishpeming, Mich.; one to the Gold King Mines Co., Silverton, Colo., and one to the Yak Mining, Milling & Tunnel Co., Leadville, Colo.

THE Cyclone Drilling Machine Co. of Orrville, Ohio, reports that the Economy blast hole loaders, formerly manufactured by Cope & Cornelius, are now manufactured by them, and that orders for loaders are coming in rapidly from the United States, Mexico and Canada. They also report having many orders for Cyclone contractors drills and coal and water well machines.

J. W. DUNTLEY, president Chicago Pneumatic Tool Co., sailed on the 18th inst. on the Kaiser Wilhelm II for a five weeks' trip to Europe in the interest of the pneumatic tool business, taking with him five styles and sizes of electric drills. Tests and orders await Mr. Duntley's arrival for the purpose of having him demonstrate these tools before the orders are placed elsewhere, as was contemplated previous to the announcement of his expected trip, and he has reason to believe he will secure the business.

STEPHENSON BAR BELT DRESSING is for use where a belt transmits power. Put up in stick or solid form, it can be carried in the tool box. There is no waste, as friction effects an even distribution. Stephenson dressing is carried in stock by the Mine & Smelter Supply Co., Denver, Colo., Alex. Helms Belting Co., L. P. Degen Belting Co. and E. C. Atkins & Co., San Francisco, Cal., and by the latter concern at Portland and Seattle. The Stephenson Mfg. Co. at Albany, N. Y., will send, postage prepaid, a free sample of their Red Label brand for leather belts, or Green Label brand for rubber or canvas belts, to any address in the world.

THE A. S. Cameron Steam Pump Works of New York City write that they have transferred their agencies to and are now represented by Cary & Fielding, 1711 Tremont street, Denver, Colo.; Utah Mining, Machinery & Supply Co., 228 South West Temple street, Salt Lake, Utah; Ingersoll-Sergeant Drill Co., El Paso, Texas; Victor M. Braschi & Co., Cadonast street, No. 2, Mexico City, Mexico. These firms will carry a full line of the Cameron pumps and repair parts in stock, and doubtless will be able to fill all orders on shortest notice. In addition to the stock transferred, three carloads of pumps and parts have been received by Cary & Fielding and a carload each by the Utah Mining, Machinery & Supply Co., the Ingersoll-Sergeant Drill Co. and Messrs. Victor M. Braschi & Co., so that they are all equipped and ready for business.

## Latest Market Reports.

SAN FRANCISCO, April 28, 1905.

### METALS

SILVER.—Per oz., Troy: London, 26½d (standard ounce, 925 fine); New York, bar silver, 57c, refined (1000 fine); San Francisco, 57c; Mexican dollars, 46c, San Francisco; 44½c, New York.

The customs value of the Mexican dollar on goods invoiced from Mexico on and after May 1st will be 49.8 cents, this being the gold standard value in Mexico.

On all goods from other countries invoiced in Mexican dollars the value of the latter will be computed at 47.7 cents, the bullion value of the Mexican dollar.

This is in accordance with a circular of instructions from Secretary Shaw.

COPPER.—New York: Standard, \$15.25; Lake, 1 to 3 casks, \$15@15.25; Electrolytic, 1 to 3 casks, \$15.75; Casting, 1 to 3 casks, \$15.00. San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18@24c. London: £66 5s spot per ton.

LEAD.—New York, \$4.50; Salt Lake City, \$3.50; St. Louis, \$4.12½; San Francisco, \$3.70, carload lots; 4½c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5½c; pig, \$4.85. London: £12 6s per long ton.

SPELTZ.—New York, \$6.00; St. Louis, \$6.15; London, £24 per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

TIN.—New York, pig, \$30.20@30.50; San Francisco, ton lots, 31½c; 500 lbs., 32c; 200 lbs., 32½c; less, 33½c; bar tin, 35@37½c. London, £139.

PLATINUM.—San Francisco, crude, \$18.50 per oz.; New York, ingot, \$19.50 per Troy oz. Platinum ware, 75@82c per gram.

QUICKSILVER.—New York, \$40.00@41.00, large lots; London, £7 12s 6d; San Francisco, local, \$38.00 per flask of 75 lbs.; Denver, \$45.00.

BABBITT METAL.—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c.

SOLDER.—Half-and-half, 100-lb. lots, 20.50c; San Francisco, Plumbers', 100-lb. lots, 17.25c.

ZINC.—Metallic, chemically pure, 50c; dust, 40c; sulphate, 30c.

NICKEL.—New York, 55@60c per lb.; ton lots, 40@47c.

ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

ALUMINUM.—No. 1, 99%, small lots, 37c per lb.; 100 lbs., 35c; 1000 lbs. 34c; ton lots and over, 33c, Pittsburg. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburg.

### STRUCTURAL MATERIALS.

IRON.—Pittsburg, Bessemer pig, \$16.35@16.85; gray forge, \$16.65; San Francisco, bar, 3c per lb., 3½c in small quantities.

STEEL.—Bessemer billets, Pittsburg, \$23.00@27.00; open hearth billets, \$23.00@27.00; San Francisco, bar, 7c to 12c per lb.

WHITE LEAD.—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, ½c per lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, ½c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c.

LIME.—Santa Cruz, \$1.25 country, \$1.25 city per bbl.

CEMENT.—Imported, \$2.15@2.65 per bbl.; California, carload lots, \$1.90 f. o. b. at works; small lots, \$2.20 per bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

NAILS.—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.55; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d, Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4d and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

LUMBER.—(Retail): Pine, ordinary sizes, \$24.00@5.00; extra sizes higher; redwood, \$28.00@30.00; lath, 4 feet, \$4.50@5.00; pickets, \$21.00@shingles, \$2.50 for No. 1 and \$2.25 for No. 2; shakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00@35.00.

### GENERAL SUPPLIES.

ANTIMONY.—New York, Cookson's, 7½c; Hallett's, 7c; San Francisco, 1000-lb. lots, 9c; 300@500-lb. 9½c; 100-lb. lots, 10½c.

COAL.—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lot, Eastern and foreign: Wallend, \$7.50; Brymbo, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8.00; Cumberland, \$13.00; Cannel, \$8.50; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13.00 in sacks; Sunnyside, \$8.50, long ton.

POWDER.—F. o. h. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1\*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1\*\*, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg.

CAPS.—3x, \$5.50@6 per 1000; 4x, \$6.50@7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

FUSE.—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

CANDLES.—Granite 6s, 16 oz., 40s., 11c per set; 14 oz., 40s., 9½c.

CHEMICALS.—Cyanide of potassium, 98%—99%, jobbing, 23@24c per lb.; carloads, 23@23½c; in tins, 30c; soda ash, \$2.00 per 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c per lb.; Cal. s. soda, bbls., \$1.10@1.20 per 100 lbs.; sks., 90c@1.10; chlorate of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2½c; powdered sulphur, 2½@2½c; flour sulphur, French, 2½@—c; alum, \$2.00@2.25; California refined, 1½@2c; sulphide of iron, 8c per lb.; copper sulphate, 5½@5½c; chloride of lime, spot,

\$2.50@2.75; sulphuric acid, in carboys, 66% B, 1¼@2c per lb.; nitric acid, carboys, 8c per lb.

OILS.—Linseed, boiled, bbl., 60c; cs., 65c; raw, bbl., 58c; cs., 63c; Lucol oil, boiled, bbl., 51c; cs., 56c; raw, bbl., 49c; cs., 54c. Kerosene—Pearl, per gal., 19c; As; tral, 19c; Star, 19c; Extra Star, 22c; Ecocene, 21c; Elaine, 25c; Water White, in bulk, 12½c; Mineral Seal Iron bbls., 18c; wooden bbls., 20½c; cs., 24c; Minera; Sperm, cs., 26½c; Deodorized Stove Gasoline, bulk, 16c; do., cs., 22½c; 8½c Gasoline, bulk, 25c; do., cs., 31c; 8½c Naptha or Benzine, deodorized, in bulk, per gal., 13c; do., in cs., 19½c; Lard Oil, E. W. S., bbl., 75c; cs., 80c; Neats-foot Oil, pure, bbl., 63c; cs., 78c; Sperm, crude, 63@68c; Natural White, 63c; Bleached, do., 57c; Whale Oil, cs., 52@57c.

BORAX.—Concentrated, 6@7c per lb.; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

BONE ASH.—Extra No. 1, 5@6c per lb.; No. 1, 4@5c.

LITHARGE.—Pure, in 25-lb. bags, 8@9c per lb.

MOLYBDENUM.—Best, \$2.75 per lb.

CHROMIUM.—90% and over, 80c.

PHOSPHORUS.—American, 70c.

SODIUM.—Metal, 50c.

BISMUTH.—Subnitrate, 80c.

URANIUM.—Oxide, 80c.

MERCURY.—Bichloride, 75c.

TUNGSTEN.—Best, 125c.

SILVER.—Chloride, 90c per oz., 90c@1.00; nitrate, 55c.

RED LEAD.—500 lbs. and over at one purchase, 7c; less than 500 lbs., 7½c.

MANGANESE.—Black oxide, 2½@4c.

MAGNESIUM.—Pure, N. Y., \$1.60.

FIRE BRICK.—Domestic, carloads per 1000, f. o. b., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skewback, \$30.00; circle, \$32.00.

FIRE CLAY.—Domestic, per ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, \$8.50.

## New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast inventors:

FOR THE WEEK ENDING APRIL 18, 1905.

787,654.—LUBRICATOR—C. H. Almond, Seattle, Wash.  
787,713.—TRACE FASTENER—C. R. Austin, Lind, Wash.  
787,432.—FURNACE—Brett & Benton, Los Angeles, Cal.  
787,696.—SHOVEL—M. Cahill, San Francisco.  
787,532.—CARP HOLDER—M. E. & W. O. Carley, Colfax, Wash.  
787,662.—RIBBON PAPER FEEDER—E. D. Castorline, San Francisco.  
787,568.—AERIAL CABLEWAY—F. R. French, San Francisco.  
787,621.—SUCKER ROD—E. R. Graham, Bakersfield, Cal.  
787,515.—TOY—L. H. Hunter, San Francisco.  
787,450.—MATTRESS—Eva K. Jacobs, Everett, Wash.  
787,516.—GAME—P. W. Jannoch, Pasadena, Cal.  
787,452.—CARP HOLDER—L. Johnson, Seattle, Wash.  
787,531.—ROTARY ENGINE—P. Magee, Los Angeles, Cal.  
787,783.—GLASS BEVELING MACHINE—J. H. McBride, Lompoc, Cal.  
787,388.—CARPET CLEANER—A. E. Moorhead, Oakland, Cal.  
787,884.—CARPET CLEANER—A. E. Moorhead, Oakland, Cal.  
787,461.—SHOW CASE—C. F. Murray, Los Angeles, Cal.  
787,635.—OIL BURNER—A. Phinney, San Francisco.  
787,799.—GLOBE SUPPORT—L. L. Smith, San Francisco.  
787,787.—SPRING LAUNCHER—E. T. Turner, Sacramento, Cal.  
787,811.—CURRENT WHEEL—P. M. Warren, Nyssa, Or.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

GAS LIGHTING DEVICE.—No. 786,928. April 11, 1905. A. F. Williams, Berkeley, Cal. The object of this invention is to provide a means for holding matches, tapers or like lighters so that they may be extended to ignite gas from burners or apparatus which is otherwise beyond the reach of an ordinary person. The device consists of a long handle having ferrules at the ends and an intermediate portion provided with an adherent friction strip spirally wound thereon, whereby its edges meet to form a substantially smooth and flush surface, and a match holder fixed to the end of the handle and extending in the direction of the length thereof, said holder composed of spring wire bent upon itself to form two members, one standing parallel with the other, one of said members being also bent upon itself to form a third portion which extends substantially parallel with the other members and beyond the first named bend and is fitted to the ferrule end of the handle, and other details of construction adapted to bring about a new and useful result.

ADJUSTOR FOR DEEP WELL SUCKER RODS.—No. 787,621. April 18, 1905. Edwin R. Graham, Santa Barbara, Cal. The object of this invention is to provide a convenient and practical means for adjusting pump valves without the necessity of uncoupling the sucker rods from the walking beam and then having to pull up or lower the rods by a cumbersome mechanism of rope and tackle. In oil and other deep wells it is necessary from time to time to effect a readjustment of the pump valves according to the nature of the well and other causes. Various types of adjusters are in use, but they generally employ a form of friction grip on the exposed part of the sucker rod, and trouble from slippage is of frequent occurrence, since the sucker rod may be several hundred feet in length and very heavy. It consists in the combination of a walking beam, a sucker rod, a pump rod, and the pump valves of the well, and a lower valve of the well unit connected to the sucker rod, a threaded rod connected to the union, and a yoke from which the threaded rod is suspended, said yoke consisting of a single piece of metal folded upon itself and with its light spread or open to receive and embrace the end of the walking beam, and having its side arms converging downwardly, and opposing clamp members on said arms and adapted to clamp the threaded rod, said yoke and clamp members consisting of a unitary structure.

SHOVEL OR SPADE.—No. 787,660. April 18, 1905. Michael Cahill, San Francisco, Cal. The object of this invention is to provide a serviceable, practical implement of this character especially suitable for operating in heavy mud, such as "adobe," or in plastic soils where it is often difficult to detach the soil and load from the soil and to unload the soil. The invention encompasses the peculiar perforations of the blade of the shovel or spade to prevent the dirt sticking to the blade and providing a removable attachment for the top of the blade which will afford a broad resilient support for the foot in pressing the implement into the ground and which will protect the foot from injury in case it slips off the blade. It consists of a pressure plate for spades and shovels, having means of attachment with the blade thereof and a roller disposed at the end of and transverse to the plate.

AERIAL CABLEWAYS.—No. 787,569. April 18, 1905. Frederick R. French, San Francisco, Cal. This invention relates to apparatus for the movement of a burden or burden carrier in either a horizontal or a vertical direction by means of cables suspended between two supports and adapted automatically to dump a burden in midair from the containing burden carrier at the will of the operator. The object of this invention is to provide a suitable support for the fall lines and a safe method of dumping in midair. It consists in a hoisting and conveying apparatus, the combination with an overhead trackway and a carriage thereon, of two fall line sections supported from the carriage, a block carried by each section, a flexible connection between said blocks, a burden carrier on said flexible connection, and means operatively for the movement of one block relative to the other to effect the dump.

# MINE TELEPHONES

## OFTEN SAVE LIFE.

Serious accidents would be much less frequent if prompt communication could be had with the above-ground authorities of a mine.

Many a father could be saved to his family if he could receive prompt aid from experienced hands. If a premature explosion should occur, and men torn and disabled, the foreman could immediately send a hurry call for the ambulance, and by the time the hoist had raised its half-alive burdens to the surface, experienced hands could begin at once to keep them alive.

## Stromberg-Carlson Mine-a-Phone Systems

are readily installed, are remarkably durable under all the trying atmospheric conditions peculiar to a mine. They are protected from dampness, oxidation and loss of current by our exclusive processes. They are warranted to convey a clear, "strong" message without rumble or buzz, and always ready for business.

A STROMBERG-CARLSON MINE-A-PHONE is never an expense—it's a dividend-paying investment. No regrets are registered of those who once install them. Send for Bulletin No. 10-M telling all the vital reasons.

**STROMBERG-CARLSON TEL. MFG. CO.**  
ROCHESTER, N. Y. CHICAGO, ILL.  
ADDRESS NEAREST OFFICE.

**SURFACED PROTECTED**

## PROTECT YOUR ROOF!

**UNSURFACED UNPROTECTED**

When you do, buy **H&H Marble Faced Roofing**. Never buy an unsurfaced roofing when you can get a surfaced roofing (**H&H MARBLE FACED**) at about the same price.

**H&H MARBLE FACED ROOFING** won't wear out, crack or melt. **LIGHTEST—STRONGEST—BEST.** Not affected by vapors, steam or acid. Any workman can lay it. Requires no painting or patching. *Samples and prices by mail.*

## PIONEER ROLL PAPER CO.

LOS ANGELES, CAL.  
H. R. WILLIAR, Sales Agent for San Francisco, 214 Pine Street.  
R. B. TOLSON & CO., Seattle, Wash. A. J. CAPRON, Portland, Or.

## The Pierce Gold Separator and Amalgamator

—FOR—  
Mills, Cyanide Works, Dredges and Placers.

These Rifles will save more gold than plates. Can be dressed and cleaned up without stopping the mill. Will save slimes that float on top of the water. Takes only from 2 to 8 square feet of space in mill and has nearly 12 feet amalgamating surface in length. Capacity up to 50 tons each in 24 hours.

Write for Catalogue 10.

**L. S. PIERCE, Patentee and Manufacturer,**

1653 WELTON STREET, DENVER, COLO.

**Selling Agents**

Mines & Smelter Supply Co., Denver, Colo. Aills-Chalmers Co., Chicago, Ill.  
Fairbanks, Morse & Co., Denver, Colo. Colorado Iron Works Co., Denver, Colo.

523 Market St., San Francisco, Cal.

Wholesale and Retail Dealers In

**HIGH GRADE Gas and Oil Engines and Centrifugal Pumps,**

MOTOR AND BELT DRIVEN,

for Irrigation, Drainage, Dredging, Cyanide Plants and for Water Works.

OUR PLANTS SUCCEED WHERE OTHERS FAIL.

Send for Circulars.

## LUFKIN Steel Tapes

ARE INDISPENSABLE FOR ACCURATE WORK.

MADE BY **The Lufkin Rule Co., - - Saginaw, Mich.**

For Sale Everywhere. Send for Catalogue.

## Water Wheel Governors

For Impulse Water Wheels of all descriptions; Electric Light, Power, Railway Stations, and all Mine Work.

We Are Now Prepared to

**GUARANTEE ABSOLUTE SATISFACTION.**

Write for References in Your Locality.

**The Replogle Governor Works,**

455 High Street, AKRON, OHIO.

## DELINQUENT SALE NOTICE.

**GOLDEN WEST MINING COMPANY.**—Location of principal place of business, San Francisco, California; location of works, Tuolumne County, California.

Notice—There are delinquent upon the following described stock on account of assessment (No. 4) levied on the 11th day of March, 1905, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Cert.	Shares.	Am't.
Geo. F. Buck .....	31	2000	\$20 00
F. O. Gardiner.....	60	625	6 25
J. J. Kelly.....	70	100	1 00
Catherine Kelly.....	71	100	1 00
S. E. Hughes.....	72	100	1 00
Mrs. Ellen Kuhns.....	82	1200	12 00
E. Gentili.....	83	500	5 00
Geo. Chas. Berg.....	100	1000	10 00
Geo. Marks.....	101	250	2 50
R. V. Hanks.....	117	100	1 00

And in accordance with law and an order from the Board of Directors, made on the 11th day of March, 1905, so many shares of each parcel of such stock as may be necessary, will be sold at public auction at the office of the company, 207 Battery street, Room 15, San Francisco, California, on SATURDAY, the 13th day of May, 1905, at the hour of 2 o'clock P. M. of said day, to pay said delinquent assessment thereon, together with costs of advertising and expenses of sale.

CHAS. BOVONE, Secretary.

Office—207 Battery street, Room 15, San Francisco, California.

## DELINQUENT SALE NOTICE.

**ALTA SIERRA GOLD MINING COMPANY.**—Location of principal place of business, Room 620, Kohi (formerly Hayward) Building, 406 Montgomery street, San Francisco, California; location of works, Sierra County, California.

Notice—There are delinquent upon the following described stock on account of assessment of thirty (30) cents per share, levied on January 28th, 1905, the several amounts set opposite the names of the respective shareholders, as follows:

Names.	No. Cert.	Shares.	Am't.
H. A. Keller.....	42	2809	\$ 842 70
M. H. Mead.....	27	100	150 00
M. H. Mead.....	28	500	150 00
M. H. Mead.....	29	556	166 80
Wm. H. Mead.....	48	6000	1800 00
Thomas C. Pedlar.....	3	5	1 50

And in accordance with law and an order from the Board of Directors, made on the 26th day of April, 1905, so many shares of each parcel of such stock as may be necessary, will be sold at the office of the company, Room 620, Kohi (formerly Hayward) Building, 406 Montgomery street, San Francisco, California, on WEDNESDAY, May 17th, 1905, at 12 o'clock M. of said day, to pay the delinquent assessment thereon, together with costs of advertising and expenses of sale.

SAM. W. CHEYNEY, Secretary.

Office—Room 620, Kohi (formerly Hayward) Building, 406 Montgomery street, San Francisco, California.

**THE CALIFORNIA DEBRIS COMMISSION** having received application to mine by hydraulic process from E. H. Wakeman, N. H. Lang and J. B. Cronan, in Alturas and Ramona Mine, near Cromberg, Plumas County, Cal., draining into tributary of Long Valley Creek which reaches Middle Fork of Feather River, gives notice that a meeting to receive any protests will be held at Room 68, Flood Building, San Francisco, Cal., May 1, 1905, at 1:30 P. M.

THE disastrous explosion which recently wrecked the Mexican dynamite factory was probably anticipated by most Americans who were familiar with conditions there, but the disaster was delayed somewhat longer than had been expected. The making of nitro explosives is always attended with extreme danger, for there are certain peculiarities of the fickle compound which are not understood by those who make it, or deal in it, or who are thoroughly familiar with the chemistry of the process. One mystery which baffles all attempts at solution is why there is an interval of some seconds' duration between explosions at the time of the destruction of powder works. This is a phenomenon which has been frequently noted and commented upon, but as yet without satisfactory explanation. In one instance in California there was an interval of fully ten seconds between the explosion of the mixing house and that of the magazine, 600 feet distant. These two structures were connected in no way by pipe, flume, wire or otherwise. On this occasion there were a series of explosions, great and small, lasting over a period of twenty seconds or more.

THE recent decision of the Supreme Court of Montana, in giving to F. A. Heinze the Minnie Healey mine at Butte, is important in that it establishes the validity of a verbal agreement to transfer mining property. Miles Finlan, formerly owner of the Minnie Healey mine, expended something over \$50,000 in its equipment and development. It is claimed that he offered the property to Heinze for about what he had expended upon it, which offer, upon examination, Mr. Heinze accepted. Mr. Finlan left at once for the East, and Heinze took possession of the mine and began a crosscut into the hanging wall. Owing to the sudden departure of Mr. Finlan, no papers were drawn up nor was official record of the transaction made. A few days later the miners employed by Heinze ran into a body of rich copper ore, and the story is that upon learning of this Mr. Finlan attempted to repudiate the transaction and claimed the property.

## Important Mining Decision.

The mining law, or, rather, its interpretation, is constantly undergoing changes by reason of the decisions of the higher courts. One of the most important of these recent phases of judicial legislation is the decision of the United States Supreme Court in the case of the Creede & Cripple Creek Mining & Milling Co. v. the Uinta Tunnel Mining & Transportation Co. In this case the former company owned a mine in the Cripple Creek district of Colorado and had applied for and received a United States patent for their claim. The latter company is the owner of a tunnel right, located prior to the issue of patent to plaintiff, and had driven a tunnel several hundred feet to the line of the former company's property, through their claim and beyond to veins not apexing at the surface (not an uncommon occurrence in the Cripple Creek district of Colorado). The Cripple Creek Company then sought to restrain the tunnel company from passing through the property owned by plaintiff, by means of the tunnel, the action being also for the possession of certain mining claims and for damages. On motion of defendant the action was removed to the United States Circuit Court for the district of Colorado, where also, on its motion, the pleadings were reformed and the action made one for the possession of the property and for damages. The plaintiff, in an amended complaint, alleged ownership of certain lode claims for which it had obtained patent without adverse from the tunnel company, and claimed that the patent related back and took effect of the date of alleged discovery of the vein, for all purposes given and provided by the laws of the United States and the State of Colorado concerning mining claims. One of the important matters decided was the relative rights of the owners of unpatented and patented claims. Without here going into details of the several contentions of the parties to this suit, it may be stated, for brevity, that the Circuit Court of Appeals reversed the decision of the lower court and decided for the defendant, the tunnel company. The Supreme Court of the United States, being called upon to review the judgment of the Circuit Court of Appeals, the higher court rendered a decision which can not fail to be far reaching in its effect and to entirely change the aspect of the rights of tunnel and other claimants to pass through the country rock under the unpatented surface of their neighbors, in order to reach unknown veins and deposits lying beyond. Heretofore this right had been uniformly denied, but the opinion of the Supreme Court, written by Mr. Justice Brewer, now, under certain conditions, permits this privilege. In the original opinion, handed down January 30, 1905, the court said, quoting from the statutes, section 2322: "The \* \* \* locators shall have exclusive right of possession and enjoyment of all the surface included within the lines of their locations, and of all veins, lodes and ledges throughout their entire depth, the top or apex of which lies within such surface lines extended downward vertically, although such veins, lodes or ledges may so far depart from the perpendicular in their course downward as to extend outside the vertical side lines of such surface locations." Continuing, the court used the following language: "So that the vested property right of the locator is limited to the surface and the veins apexing within its boundaries. Undoubtedly, therefore, until the entry (for patent) of the plaintiff's lode claims, and possibly until the issue of the patent, the defendant had the right to drive its tunnel through the subsurface of the plaintiff's lode claim. That ground still remained the property of the Government, and was free and open to exploration." To this decision considerable dissatisfaction was expressed, and the Cripple Creek company strenuously urged upon the Federal Supreme Court the advisability of a modification of recession from its position. The application for rehearing, however, failed of any result beyond the elimination of the doubt under the opinion as first written, as to the right of subsurface exploration between the time of final entry and payment and the time of issuance of patent. The doubt was clarified by the insertion, in place of the foregoing excerpt, of the following:

"The express grant to the locator made by this section (2322 R. S.) includes only the surface and the

veins apexing within the boundaries of the location. Until, therefore, by entry and payment to the Government, the equitable title to the ground passes to the locator, he is in no position to question any rights of exploration which are granted by the other provisions of the statute. The fee still remains with the Government."

## Mining Taxes in Mexico.

Mining conditions in Mexico are undergoing many important changes, particularly in the relations of the industry to the Government, which has recently made important concessions to the mine operators. Under existing laws, the mine operator never gets title to his mine, but holds it by paying taxes on the area claimed, the unit being the pertenencia, which is 100 meters square (10,000 square meters). No matter how many years the owner may have been paying taxes on his property, he is owner in name only, and should he fail in the prompt payment of these taxes, no matter how valuable or extensive the mine, or the length of time it has been in continuous operation, the property is seized by the Government for such default in payment of Federal taxes. The taxes are payable in advance every four months, or, at the option of the operator, may be paid in advance annually. The mine owners are making an effort to have such legislation passed as will give the mine owner a title in fee to mining claims upon which the tax has been paid for a stipulated number of years, this being as yet an undetermined period. The recent concessions made in the discontinuance of the levy of certain taxes will, it is estimated, make a difference of about \$4,000,000 annually to mine owners, which is a very substantial concession, and one which had been earnestly sought. The industry in Mexico has grown to such relatively stupendous proportions within the past decade that the Government could afford to make this concession, and wisely concluded, evidently, that it would stimulate mining investment still further, and that eventually the State will derive a greater benefit than under the previously existing conditions.

## Iron Anvil Blocks.

Managers of stamp mills on the Rand, South Africa, are endeavoring to increase the capacity of their hatteries, and in some instances have put in heavy iron anvils below the mortars, an idea derived from recent American practice. One of the first mills to install the iron anvil was the Village Deep at Johannesburg, where 14-ton blocks have been put in, resting on a cushion of heavy timbers which are placed on a concrete foundation, presumably in fear of the disintegration of the concrete, if the anvil blocks were placed directly on the concrete. If the concrete is made from suitable materials, in proper proportion, there should be no difficulty on this score, particularly in a region where extreme cold is unknown. It is true the vibration of a stamp battery is very great, but this vibration is largely absorbed by an iron block of fourteen tons weight. In the experience with the heavy steam stamps in the Lake Superior mills, it was at one time thought necessary to place heavy timbers beneath mortars, to avoid the rigidity now sought in stamp mill construction; but it was found that the iron anvil block gave an increased capacity and the "spring" timbers were abandoned. It is not unlikely that the greater number of stamp mills built in the future will be constructed with this idea of great rigidity in mind, and heavy anvils beneath the mortars become as common as wooden mortar blocks have been heretofore.

NOTWITHSTANDING the fact that iron making in blast furnaces of various types has been carried on for centuries, and the art has reached a high degree of perfection, there is comparatively little known of the reactions which take place in the furnace. The various improved steps in the perfection of iron blast furnace practice have been the result of previous experience and observation, rather than of scientific knowledge; in fact, the great progress that has been made has been the result of experiments, and often these have proven both expensive and unsatisfactory. This must continue to be the case until some more definite knowledge is gained, by which further experiment and improvement may be gauged and directed.

## CONCENTRATES.

TROY WEIGHT is used to measure gold, silver and precious stones. An avoirdupois pound (16 ounces) equals 14.58 troy ounces.

LITTLE good can be accomplished by filing the piston of a machine drill or of an engine of any description with a rasp or other type of coarse file.

BAILING SKIPS should be so constructed that they will not strike the surface of the water squarely, as this is likely to damage the skip and throw it off the track, if not held by guide rails.

THE beds of bituminous sand found in California and elsewhere are supposed by geologists to be petroleum-bearing strata, from which the volatile constituents have to a great extent disappeared.

DRY WASHING placer machines are successfully used where the gold-bearing material is light, dry and not cemented in any manner by lime, iron, clay or other minerals. These machines are usually of limited capacity.

CALCIUM SULPHATE has the property of retarding the setting of hydraulic cement. Up to a certain percentage the gypsum increases the strength of cement, but too large an amount has a tendency to cause disintegration.

IN making tests of mercury in the presence of salt (NaCl) and bluestone ( $\text{CuSO}_4$ ), it is important as to the relative amount of each of the substances used, for the reactions obtained with varying quantities of bluestone are widely different.

THE losses by chlorination process are ascribed by some metallurgists to the presence of lead in the charge, which is present in the ore, or concentrates in the form of galena which in roasting is reduced to metallic lead, occasioning a loss of gold.

STULLS may be safely employed up to a length of 20 feet, if the weight to be supported is not too great. Sometimes where long stulls are used it is a good idea for safety to place sprags at the centers reaching from stull to stull, thus securing greater rigidity.

THE Washoe smelter at Anaconda, Mont., is 25 miles from the mines, which are at Butte. The ore is transported in 50-ton steel cars. About 5000 tons of ore are treated at that plant daily, and the sulphurous fumes, if all converted into sulphuric acid, would produce over 2000 tons daily.

IT is a difficult thing to represent a plan and section of mine workings and also the geography and topography in a single sketch, as many attempt to do. It is only by long association with those who practice this method of description that the meaning of the person making such drawings can be comprehended.

THE occurrence of native sulphur in veins is due in most instances, if not always, to the oxidation of pyrite or other base metal sulphides. Instances of the occurrence of native sulphur rich in gold have been mentioned herein in the past, one notable occurrence being that at Cedros Island, off the coast of Lower California.

THE only safe device to attach a windlass rope to the bucket is a safety hook, which may be quickly detached when desired, but which will not release when the bucket strikes the walls or timbers of the shaft going either up or down. "Pigtail" hooks, looped ropes and other make-shift arrangements are dangerous and should not be used.

IT is not common to find alkaline sulphides in working cyanide solutions, though small amounts frequently occur in commercial KCy. Where precipitation is accomplished by means of zinc, it is generally thought that the zinc double cyanide in the solution precipitates as zinc sulphide any small amount of sulphide which may have been present in the solution.

THE length of time required to leach a charge in a cyanide vat varies from twenty-four hours to six days. This can only be determined by experiment, and experiments should be made on as large a scale as possible. Sometimes slow leaching is the result of too deep a charge, and better results are obtainable by working more shallow charges, and a greater number of them in a given time.

PECTOLITE, a silicate of soda and lime, often gives out a light when struck or broken in the dark. This is one of the well-known properties of zinc blende, that of emitting a phosphorescent-like light upon being broken or scratched. The property is of no known value. Some diamonds emit light in the dark after having been exposed to the strong light of the sun. Phosphorescence is a property of fluorite.

THE speed with which machine drilling may be accomplished depends to a great extent upon the superficial

area of the hole being drilled, as well as on the area of piston and air pressure. For this reason a small piston drill will often make as rapid progress in cutting, using a small bit, as a large machine using broad bits. In easy ground, or even "middling hard" ground, small drills— $\frac{1}{4}$ -inch to  $\frac{3}{4}$ -inch pistons—will often prove more economical than large machines using heavier steel and wider bits.

THE occurrence of native mercury in a cinnabar mine is not viewed with any particular satisfaction by the management, as it has been found that the native metal usually occurs near the bottom of an ore deposit, and its appearance has come to be considered by some as an indication of the "petering out" of that particular deposit in depth. Quicksilver in the form of cinnabar occurs in many different kinds of rocks, but is found in commercial quantities mostly associated with sandstone and serpentine.

THE State Legislature of California several years ago passed a law fixing a code of bell signals for use in mines of that State. While the State law does not plainly make it compulsory to use this State code, it clearly places the responsibility of any accident occurring through failure to use the code upon the management of the mine where such accident occurs. The code is in use throughout the State of California, with a few exceptions, and all who have used it agree that it is the best code thus far suggested by any State or body of miners.

A "TUNNEL LOCATION," as contemplated by the United States statutes, entitles the owner of such tunnel to only such veins cut by it that have not been previously discovered and located by others. As there is sometimes doubt as to the identity of a vein intersected by a tunnel or other workings at depth, it is occasionally necessary for the apex claimant of a vein to raise or sink on his vein from the level of the tunnel to the surface in order to prove the identity of his vein from the outcrop to the point at which an adverse claimant has undertaken to claim it.

THE report of the United States Naval "Liquid Fuel" Board, issued the past year, states that the supply of oil which is available for fuel in the United States is, first, the small percentage (probably not over 2% or 3%) of the total production of the Ohio and Pennsylvania oil—the residuum from the process of refining; second, the crude oil from the Indiana and Ohio fields, wherever the price of oil makes the burning of oil profitable at 95 cents to \$1 per barrel (plus freight); third, those portions of the California oil which are not best suited to refining; fourth, practically the entire output of the Texas field.

THE converting of sulphide copper-iron ores into sulphates is not always an easy operation. It occurs by natural decomposition of the ores, and to some extent is accomplished by roasting, but it is an easy matter to carry the roasting too far. It must be done slowly, and is usually attempted only with those ores containing a large amount of iron sulphide and a relatively small amount of copper sulphide. The roasting is usually done in heaps when a portion of the copper in the ore becomes sulphate and a portion is turned to oxide. If the roasting is preliminary to smelting there is little need of so much care, but if the process is preliminary to leaching the formation of large amounts of oxide, insoluble in water, should be guarded against.

THE occurrence of sulphides in modern volcanic lavas, such as basalt, is very rare. Pyrites and other base metal sulphides are not essential constituents of recent volcanic rocks, but at Sulphur Bank, Cal., cinnabar (sulphide of mercury) is found impregnating basalt, as the result of deposition of this mineral from hot springs immediately underneath the lava flow. Pyrite and other sulphides are abundant under proper conditions in many Tertiary lavas, such as the andesites and trachytes, as the result of infiltration from fissures in which mineral solutions were passing. Many valuable veins and ore deposits occur in rocks of this character.

ALL mining claims in Alaska are held under federal laws. The laws concerning liability of lease and bondholders of mines are not really mining laws. In some of the several States there are laws governing the liability of lease and bondholders, and in most of these the property holder may protect himself by posting a notice disclaiming any responsibility for debts contracted by those working the claim under lease or bond. An unpatented mining claim is recognized as "property" in the strictest sense of the term, and in the absence of any legislation on the subject it is presumable that a claim owner must protect himself against debts contracted by a leaser or bondholder on his property by posting a notice to this effect.

THE advisability of using machine drills in place of hand work in stopes must be determined by existing conditions. In ore bodies of large size, where the ore and walls are hard, large machines—3-inch to 3½-inch cylinders—are certainly advisable, but in stopes where the ore is much shattered or crumbling, small machines—2-inch or 2½-inch—should be employed, or hand work substituted for machine work altogether. In small veins where there is a liability to mix the waste from the walls with the ore the rock must be broken so as to

keep the ore and wall rock separate, and generally this can be best accomplished by first breaking the wall on one side or the other—stripping the ore—and after cleaning up the waste, to shoot down the ore separately. If either wall breaks more freely from the walls than the other, it is on this side that the stripping should be done. It is usually best to strip the hanging wall if possible, as this involves less danger of the vein falling after the support of the wall is removed.

THE strain on a cable hauling on an incline is not as great as winding in a vertical shaft. The less the degree of inclination the less the strain, and consequently the less power required to haul a given load. This weight of load on inclines is directly proportional to the sine of the angle of inclination. Thus: If a load of ten tons is to be hoisted from a shaft having an inclination of 60°, the effective weight of the load is as ten tons is to the sine of 60°, or 8.66 tons. If an engine can hoist a load of five tons from a vertical shaft, this engine will hoist a ten-ton load up an incline of 30°. In this case the relation is as the cosecant of the angle. These are theoretical computations, to which must be added the friction of the wheels on axles and rails. This friction is usually figured from 30 to 100 pounds per ton, and is of greater importance on shafts of low angle than those of steep pitch, and the friction will vary more or less, also, according to the condition of the shaft. Where a change in dip occurs, the friction is greatly increased, as is also the case in very deep inclines, where the rope sags to such an extent as to drag on the timbers or run on idlers placed in the shaft. Under such conditions the friction factor may be as high as 10%.

BAUXITE is an oxide of alumina, containing alumina 73.9 and water 26.1. The bauxite of France, near Baux, occurs mostly in the form of grains in compact limestone. Other and more extensive deposits are found in old lake beds. Well-known American localities in the United States are Saline and Pulaski counties, Arkansas; Cherokee and Calhoun counties, Alabama, and Floyd, Barton and Walker counties, Georgia. The deposits in Arkansas are the most extensively worked and occur associated with eolite-syenite, a portion being due to replacement of the eolite and another part being due to decomposition of the feldspar and eolite and the precipitation of the aluminum mineral as a hydrate. The first form usually preserves the form of the eolite and is in place in bunches; the second forms beds about 20 feet in thickness which lie along the slopes of the ridges of eolite-syenite and extend some distance out into the valley as flat sheets. The ore is mined by a system of open cuts. In these deposits the successive stages of deposition are marked by layers of iron oxide, which must be hand-picked from the bauxite. The mineral is earthy and clay-like, sometimes colored pink, red and violet from presence of iron oxide. Gibbsite is very similar to bauxite in composition, but has a gray to greenish color and is usually crystallized, incrusting, or in rounded concretions. It has a smooth surface and often a faint fibrous structure within.

THERE is no material difference in the method of formation of a vein fissure and a fissure in which no mineral has been deposited. A fault fissure is one in which the walls have been subjected to a greater or less movement—the hanging wall having been shifted up or down or laterally with reference to the foot wall. A simple fissure may exist as a crack or fracture in the rock, no perceptible movement of the walls having taken place. Either of these types of fissure may occur between rocks of unlike character, as limestone and porphyry or quartzite and shale, or the fissure may cut across the stratification of the rocks both in strike and dip, or may occur wholly within one kind of rock. The only material difference between a vein and a fissure without ore is one contains ore and the other does not, and that portion of a fissure in which no ore occurs—that part between the pay shoots, for instance—is in all essential particulars the same thing as a fissure entirely destitute of ore. The most important distinction between fissures is in the comparison of those occurring in the same mine and having different strike and dip, the one intersecting the other. Miners usually refer to the later fissure as a cross-head or cross-course. Often both the older and the younger of such intersecting fissures contain ore, but usually one is much more valuable than the other. Fissures often occur cutting veins and which are simply fractures or fissures filled with broken country rock ground from the walls by movement, part of which is coarse and part is fine, all the fragments being angular; but in the fissure no ore deposition has taken place. The illustration submitted by A. E. R., from Bald Butte, Mont., indicates that there was probably first formed a fissure in which there was sufficient movement to crush the country rock between the two planes or walls of the fissure and that this crushed material was infiltrated with silica, which to a greater or less extent replaced the crushed material. Later the rock masses were again subjected to further movement, and the hanging wall slates were crushed between the main quartz vein and the subsidiary planes of displacement formed by the pressure and movement in the hanging wall. These processes are of very common occurrence, and often in some part of the vein the mineralization of this zone of later fissuring on the hanging wall—and sometimes on the foot wall—is sufficient to constitute a good body of pay rock.

## A Large Gold Dredger.\*

The Folsom Development Co. of Folsom, Cal., have recently put in commission the largest placer mining dredger that has yet been constructed in this country and what is said to be the largest placer mining dredger in the world. A great deal has been written on the subject of dredger mining, and the progress of the art has had considerable attention in this journal.

The Folsom Development Co. owns a considerable acreage on the American river just below the town of Folsom, Cal. They are at present operating two placer mining dredgers of the Bucyrus type, built by the Western Engineering & Construction Co. of San Francisco, and which have given excellent and satisfactory results. These two dredgers, one of which is shown in illustration No. 1, were put in commission about February 1, 1904, about which time the Folsom Machine Co. started work on the design and construction of the third dredger which is known as No. 3. There was much to be said on both sides of the question as to whether the larger capacity and heavier machinery of a dredger of the proposed size would prove economical and efficient, or whether the increased size of the dredger and its parts would prove a detriment rather than an advantage. The matter was, however, settled by a decision to try the experiment, it being evident that such a question could only be proven by time and the actual operation of the larger machine under conditions similar to those under which smaller machines were in general use.

The dredger design was started February 1, 1904, and power was turned on and the machine started during the earlier part of December of the same year. This is believed to be a remarkably short period for the design and construction of a dredger of this size.

Technically, the dredger is of the single lift type with continuous buckets, flat screens and rubber belt stacker. It is electrically driven and is provided with a head line anchorage, as well as spuds.

Fig. 2 shows the start of the actual work of construction of the hull. A pit has been excavated alongside the railroad, and false work put up, on which the frames of the hull are being erected. Fig. 3 shows a more advanced stage of construction, some of the superstructure, for supporting the machinery, being in place, and the hull being partially planked. This hull is 120 feet long, 43 feet wide on the water line, and 10 feet deep over all. It is built of the best quality of Oregon pine obtainable, upwards of 300 M. feet of lumber being used in its construction, and weighing when complete, ready for the machinery, about 750,000 pounds. The hull has a displacement of 24,440 pounds per inch of immersion.

To an Eastern reader the timbers used in constructing a dredger of this size may appear enormous. Large quantities of timber surfaced on all sides and ranging from 8"x10"x42' long, to 18"x24"x40' to 60' long are used, and a wooden spud, for use as a swinging spud, is used and is constructed from a single stick 30"x42" about 55 feet long. When the hull is complete and caulked, water is turned into the pit from an irrigating ditch and the hull is floated off from the false work ready for the erection of the machinery. Fig. 4 shows the condition of the hull at this time.

Fig. 5 shows the start of the work of erecting the machinery. The ladder frame has been put in place and the buckets are being strung. This ladder frame is a deep plate girder of structural steel weighing upwards of 80,000 pounds; it is suspended from a nickel steel, hollow-forged shaft 13 inches in diameter resting in heavy cast steel bearings. The lower end of the frame is provided with a heavy bail and blocks, corresponding with a tackle block, on the top of the front gantry by which the frame may be raised and lowered. The top side of the ladder frame is provided with chilled iron rollers 16 inches in diameter for supporting the chain of buckets. The bucket chain consists of eighty-two buckets of about 9 cubic feet capacity each, built to form a continuous chain, the articulations of which are forged nickel steel pins 6 inches in diameter. A bucket complete weighs 2550 pounds and consists of a massive cast steel back or link, a sheet steel hood and a cutting lip of manganese steel, all securely riveted together. At normal speed this immense chain is driven at a rate of about 45 feet to 50 feet per minute, delivering the contents of twenty buckets per minute to the hopper from which the excavated material passes to the screens.

The chain is driven by a 150 H. P. variable speed induction motor through heavy gearing, all of the shafts employed in the transmission being forged from nickel steel and all of the gears being cast steel with machined teeth. The size of the parts of this main drive may be approximated by reference to Fig. 12, the main gears being slightly over 12 feet 8 inches in diameter, the shaft on which they are mounted being 15½ inches in diameter at the center and nearly 12 feet long, weighing almost 7000 pounds. Figs. 10 and 11 show the lower end of the excavating machinery submerged and the buckets coming up

out of the water, passing up the ladder frame to deliver their contents to the hopper; No. 10 being taken from the bank nearly in front of the dredger and No. 11 taken from the heavy timbers forming the frame from which the ladder is raised and lowered, and showing the buckets passing the pilot house. The pilot house contains the switch board for distribution of the electric current to the various motors and lights, and the levers for manipulating the various clutches, brakes, etc., used in the operation of the dredger. From his windows the winchman can see his work, watch the buckets to see that he is filling them properly, and, by the shifting of levers, he can control the speed of the buckets, and, in fact, all of the operations of the dredger. An annunciator on the wall in front of him serves to notify him if any of the machinery on the lower deck should go wrong

Fig. 5.—Stringing Buckets.

and at the same time shows which of the various machines it is that may be giving trouble.

The material that is delivered by the buckets to the hopper is fed by it to a pair of huge, flat screens arranged tandem and driven by a cranked shaft at 130 strokes of 4 inches each per minute; over these screens are perforated pipes from which some 5000 gallons of water per minute is sprayed over the gravel, washing the finer portion and the values through the screens to the mercury tables below

One of the Early Dredgers.

where the values are concentrated and saved, the fine sands being washed astern of the dredger through steel sluices.

The coarse material, which passes over the screens, is delivered to a 42-inch rubber belt conveyor mounted on a steel truss which overhangs the stern of the dredger and carries the tailings astern and stacks them up to such a height that they will not interfere with the further manipulation of the dredger.

The driving end of this conveyor is illustrated in Fig. 7, the framework and idlers without the belt in Fig. 8 and the conveyor with belt in place in Fig. 9.

The electrical equipment of this dredger comprises a 150 H. P. variable speed motor for driving the buckets; a 30 H. P. var. speed motor for the main winch; 100 H. P. constant speed motor for main

pumps; 7½ H. P. for hilge pump; two 40 H. P. for sand pumps; a 40 H. P. for the screens; 15 H. P. for the stacker and over 200 16 C. P. lights. The motors are all alternating current induction motors, and all of them of 50 H. P. and over are on a 2200-volt circuit; the smaller motors are on 440-volt circuits. The current is brought on board through a heavy, insulated cable containing three No. 0 conductors. The cable may be attached to any one of three

Fig. 14.—Side View—Just Started.

Fig. 15.—Side View—With Tailings.

terminal panels, one of which is located on the front of the pilot house for use when working on a head line, the other two being placed on opposite sides of the rear end of the screen house and from these terminals it is led to the main switch and circuit breaker on the switchboard in the pilot house. The switchboard is of blue Vermont marble in three panels and is provided with the usual lamps and instruments and also with oil switches which control every circuit on the dredger. Three 30 K. W., O. D.

type transformers, 2200 to 440 volt, are provided on the lower deck for supplying the lower voltage current used by the smaller motors. These transformers are placed in a special compartment opening only to the outside of the dredger, each transformer being placed in a sheet steel tank and the compartment being lined with asbestos covered with galvanized iron for protection against possible fire. The transformers are shown in place in Fig. 13.

Fig. 14 shows the side view of the completed dredger very shortly after it commenced actual work and Fig. 15 was taken through the piles of tailings after the dredger had been in operation about a month. The theoretical capacity of a dredger of this size should be nearly 8000 yards bank measure per day, but such theoretical capacity is not attained in

\* See illustrations on front page.

actual work, 50% to 55% of the theoretical capacity being the average in actual work.

This dredger therefore may be expected to handle from 125,000 to 140,000 cubic yards per month on an average, and the problem to be worked out on this machine is whether the larger machine, with its proportionally greater capacity, will so reduce the cost of handling the material that lower grade ground, that has heretofore been considered unprofitable, may be made available.

This dredger was designed by and constructed under the supervision of George L. Holmes, formerly in

As a rule, the pay gravel is not cemented, but in some places bordering on the foot of the hills it is slightly so. The conglomerations of gravel occasionally encountered are not very hard and are easily broken with hammers. The bedrock is brown slate and diorite, lying in parallel bands, having a trend N.-N.W. and S.-S.E. and dipping to the east 25°. The average depth of the pay gravel, which is next to bedrock, is about 4 feet. The whole depth of overlying gravel and loam to be removed by stripping is about 26 feet. The pay gravel is subsequently sluiced and the bedrock swept. All of the material

tend with about 40 miner's inches of water daily. In the winter time, during floods, about 500 and sometimes 600 inches are encountered. In the pay gravel in places or "spots" a great many coarse flat rocks, water-worn, but not large, round boulders, are encountered.

A full crew, night and day, consists of twenty-five to thirty white men, employed in running the machinery, in superintending washing pits, and watchmen for watching and bossing the Chinese. White men receive from \$1.25 to \$3 per day, with board and lodging. The wages of Chinese are \$1.25 per day, without board. The machinery has never been in full operation until this summer. It is now working to entire satisfaction. The gross production is from \$6000 to \$12,000 per month.

Altitude.....	330 feet
Course of lead.....	N.-N.W. and S.-S.E.
Nature of pay gravel.....	Loose bluish wash gravel
Nature of bedrock.....	Slate and diorite
Depth of overlying gravel and loam.....	23 feet
Depth of pay gravel.....	4 feet
Length of time worked.....	4 years
Number of men worked.....	25 to 30 white men; 80 Chinese
Gross monthly product.....	\$6,000 to \$12,000
Gold fineness.....	852 to 872

The gold, 872 fine, comes from the north side of the creek, showing that there are two sources of gold—one, probably, from the gold belt higher in the mountains, the other from the country on each side of the ravine. The gold is what is termed fine gold and in character is flattened. It is sometimes attached to small fragments of quartz which do not seem to have come from the mother lode, along which Dry creek runs, some 7 or 8 miles higher up the mountain.

Large excavations are made by mechanical removal of the gravel. In the last two months one excavation, having a length of 800 feet and an average width of 60 feet and depth of 30 feet, has been made. The material overlying the pay gravel is gripped by automatic grappling buckets, self-filling and self-dumping (engravings of which are shown), swung by machinery to the required distance and dumped. The usual load of the buckets is two cubic yards. One cubic yard of the gravel weighs 1080 pounds; one cubic yard of the loam and gravel weighs 775 pounds. Commencing at the foot of the hill at any desired point, the gravel is seized and transported to any point within a radius of the capacity of the machine. The present derricks can pile it to a height of 45 feet. The buckets are swung by a boom, which is 114 feet long and describes a semi-circle in the air of 220 feet. The bucket rises from the ground, the arm of the derrick swings toward the point designated, dumps its load and returns to refill itself, consuming from three-quarters of a minute to two minutes on the trip, according to the height it is raised and the distance swung.

At one end of the claim in the bed of the creek is a pump pit, 36 feet deep, 10 feet wide and 25 feet long, housed, in which are two centrifugal pumps for handling the water encountered in the mine. From the bottom of this pit culverts are extended in all directions as work advances. In the fall of the year a penstock is built at the heads of the culverts, and in the spring the culverts are again extended. Several important improvements in this pumping machinery have been made by Mr. Lambing, the superintendent, in the matter of annular casings and in rests for the vertical shaft of the pumps. A tappet, having a steel face on the underside and secured to the shaft by set screws, rests on two cast iron pulleys, revolving on a horizontal shaft in opposite directions. In this way the wear of the rest is reduced to a minimum. These pumps are each driven by a 16 inch Knight's wheel with turbine attachment, having twelve nozzles with apertures 2½ inches by 1 inch. The head of water above the wheel is 68 feet. A 22-inch pipe conveys water for power to drive the pumps, and there is at command 500 inches of water, with pressure of about twenty-nine pounds to the square inch. One pump is kept running at a time.

From the bottom of the pump pit, directly under the pump house and 33 feet below the surface of the ground, the culvert is started in the bedrock, to get the proper grade, and is carried along as work progresses with a grade of ¼ inch in 12 feet. The pumps are submerged and placed on the bedrock in the bottom of the pit. The culvert, 14x20 inches, is laid as fast as work goes on right up to the face of the excavation. By this means all water is drained from the ground, being worked to the pump pit. Above this culvert another similar one is laid, which carries the sluice water also to the pump pit. The bedrock culvert is kept open with a screen over the upper end. The water which is pumped to the surface is carried off by sluices. If water for sluicing becomes scarce, a portion of this water is conveyed back in pipes to use in sluicing. The culverts have branches at right angles, running to the face being worked or running in all directions where work is being carried on. The sluices in which the gold is saved have a grade of 7 inches to 12 feet; they are of a common style, with slats 3x2 inches laid flat through their entire length.

Quicksilver is sprinkled in the sluices according to the grade of the gravel, an ounce or two every two to four hours. The loss of quicksilver does not exceed twenty-five pounds per annum. The greatest loss is occasioned by retorting in the open air. Two derricks are employed; the weight of each, including accompanying machinery, is from seventy-five to eighty

Dredgers at Work in Arroyo Seco, Near Ione, Cal.

charge of the dredger department of The Link-Belt Machinery Co. of Chicago, to whom we are indebted for the illustrations and description.

In 1886 dredging operations were successfully carried on in New Zealand and the proposition of dredging California rivers began to be discussed about that time. One of the first types of dredging boat was the Ball or suction dredger, and, while dredgers of this kind have been successfully operated in harbors, handling silt and mud, they have never given satisfactory results when applied to gravel mining.

The early history of dredging in California is interesting, particularly when the machines in use in the

deposited above the pay gravel is removed mechanically by devices which are the outgrowth of working this mine. A description of the mechanical contrivances used and the methods employed at the mine, now in successful operation, after other processes were found unremunerative, is given at some length,

The Dredger Bucket Open.

The Bucket Closed.

earlier days and the methods then employed are contrasted with those of the present time. One of the first dredging operations in California was carried on at the Arroyo Seco mine, near Ione, Amador county. The following description of the remarkable machine used there in 1887 and the methods of working are thus described in the eighth annual report of the State Mineralogist of California:

This mine, also known as the Lambing, is situated in the Irish Hill district, 3 miles north of Ione, on what is called the A. D. Ranch. It is worked under a lease, purchased in 1883 from the railroad company. The original term of the lease was for fifteen years and it calls for forty-five acres, more or less. The claim is 2700 feet long, with an average width of 700 feet. It follows the bed of Dry creek in its course and extends from hill to hill on either side.

not so much for the purpose of representing a local mining plant, as to call attention to a novel way of handling a gravel mine, which undoubtedly is applicable to numerous other sections in this State, though ground has never been worked in this manner elsewhere. The mining operations are carried on principally in the dry season, and in the bed of a creek and on its sides, with the water of the creek turned from its course. The claim has been worked for four years. During this time the machinery here employed was invented and built as its adaptability was ascertained. The width of the pay channel varies. It is supposed that it pays for about 700 feet in width. The creek has apparently changed from every point, from hill to hill, from time to time in years gone by. Under the present system of working no timbering is required. In the dry season the mine has to con-

tons. The length of the boom, the outer end of which is elevated 58 feet, is 114 feet; it is capable of carrying a load of seven tons, but usually lifts about two cubic yards of gravel. The boom is made of Oregon pine, 12x18 inches at the foot, 12x24 inches in the middle and 12x12 inches at the outer end, where a 4-foot sheave is located, which carries the hoisting cable, a flexible steel wire rope, 1 inch in diameter. Before using tar, two ropes per annum were required. After using tar occasionally, one rope only was needed yearly. By tarring every three or four days, the rope has kept in good condition for the last two years. The machine is handled by an operator, called a lever tender, who stands about 50 feet above the foot of the mast, in a little house near the top of the mast, where levers are attached by gaspipe to the machinery below. All is under the management of this man, who, owing to his elevated position, has full view of the surroundings and perfect control of the entire operation.

The steam cylinder is located on top of the bucket; the steam passes through inch gaspipes of various lengths, connected with globe and socket joints for flexibility.

Carbolized steam hose, which was at first used, was found to be insufficiently durable to be effective.

The pipe connects the cylinder with the steam drum of the boiler of the derrick. As soon as the bucket on descending has reached the gravel, steam is turned into the cylinder by means of a five-way valve below the piston head. This causes the piston rod to rise and draw together the clamping parts of the bucket which enfold the load; by turning the valve still farther, the steam enters above the piston head, forces the rod down and empties the bucket; turned still farther, the steam escapes. Each derrick has two boilers and two engines provided with link motion. Two of the engines have 9x12-inch and the two others 8x12-inch cylinder and stroke respectively. In order to furnish dry steam for greater effectiveness, a large steam drum has been placed over each of the two drums on the boilers of each derrick. Each of these derricks consume about 4½ tons of lone coal in twenty-four hours, an equivalent of about 4½ cords of pine wood.

The cost of the coal delivered at the derricks is \$2 50 per ton of 2000 pounds. The derricks are easily moved forward and backward by the same engines that hoist the buckets. By throwing a clutch in gear, they become locomotives and run forward or backward at will. The machine rests on a solid railroad track, with 16-foot gauge, and the heaviest rails are employed. The track is laid on heavy Oregon pine timbers 12x16 inches in size. Twice as much track is laid as the derrick covers. As the derrick advances, the length of timber behind is removed to the front. If the movement is backward, the track in front is removed and laid in the rear. The cost of a single derrick has been about \$10,000.

In 1888 a dredger was placed on the Carson river near Dayton, Nev., to work for quicksilver and amalgam which had come down the river from the various mills working Comstock ores, but this enterprise was not a success.

One of the early dredgers in California was of the steam shovel type, with a single scoop or bucket. This was in operation on the Sacramento river near Redding, and was known as the Diestleborst dredger.

### Effect of Salt and Bluestone on Mercury in Pan Amalgamation.

TO THE EDITOR:—Practical experiments such as those described by A. E. Drucker in his interesting article on "Pan Amalgamation" in your issue of April 15 are always of value, yet I have lately heard of several mills in Sonora where the traditional salt and bluestone process has failed to give satisfactory results, and I know of one mill where a great gain has come from leaving out the bluestone from the pans altogether. At the same place experiments are now being made to determine whether it will be best to leave out the salt also. So many pan amalgamation mills are in use that it seems to be important to once more reopen the question of the use of bluestone.

It recently became necessary for me to inquire why there was such a large loss of mercury in a certain mill where the salt and bluestone process was used. Being away from all but a few reagents I could only make a few simple experiments, as follows.

Mr. Drucker notes that when quicksilver, salt and bluestone are boiled in water in a test tube the mercury soon divides into small particles which are coated with a gray substance which he assumes to be calomel. My first experiment was to boil bright, clean mercury in a solution of common salt. The mercury remained clean and bright. Hence, if a chloride of mercury was being formed it must have been the soluble corrosive sublimate ( $\text{HgCl}_2$ ) and not calomel ( $\text{Hg}_2\text{Cl}_2$ ). Of course the result might have been different if the mercury had been boiled for a very long time or had remained in the salt solution for days or weeks.

Next, clean mercury was boiled in a solution of bluestone. In a few minutes the mercury had been reduced to gray granules, many of them being microscopically small. They had no metallic luster. Next, clean mercury was boiled in a solution of salt

and bluestone mixed. Then followed what Mr. Drucker describes—the mercury was soon divided into gray granules, and the eye could not distinguish them from those formed when the mercury was boiled in the solution of bluestone alone. In other words, the quicksilver had not only been "floured" (reduced to fine globules of metallic luster), it had been "sickened" (coated with a substance having a non-metallic luster and resisting amalgamation). It thus appeared that mercury can be decomposed by copper sulphate, but I had no means of analyzing the gray coating. It cannot be calomel, for there was no chlorine in the solution. Probably one of the sulphates of mercury is formed, and if so the copper will naturally be left as a soluble sub-sulphate or as a part of the gray coating in the form of an insoluble oxide or other compound.

Of course such incomplete experiments do not warrant theories. But on the face of it the role of copper sulphate seems to consist in sickening or decomposing the quicksilver. The addition of the salt does not prevent the sickening. At this point many chemical questions naturally arise. For instance: Is the gray coating that forms on the mercury when it is boiled in the solution of bluestone the same as that which forms when it is boiled in the solution of both salt and bluestone? Is this coating a chloride or (in part, at least) a sulphate? Does zinc amalgam in the pan have any other mission than to undo a mischief already wrought by the bluestone? Is zinc chloride or zinc sulphate the result? What ores will prevent the solution of mixed salt and bluestone from attacking the metallic iron scales from the stamps, thus forming iron sulphate and metallic copper, the latter then becoming a part of the amalgam? If, in the case mentioned by Mr. Drucker, there was no copper in the amalgam, was this due to the copper having become a soluble chloride, or did it exist in some other non-amalgamable form, perhaps because of the presence of the zinc blende, the galena, etc.? What class of ores does the bluestone help to amalgamate, etc.?

If we are to use the bluestone in spite of the fact that its first effect is to decompose the quicksilver, why? If it is of use in amalgamation, the fact can be proved scientifically by exact chemical analysis and practical experiment. Has any one done so?

G. H. STONE.

The Babicanora Mine, Arizpe, Sonora, Mexico, April 23.

### The Lead Fields of Laurium, Greece.

Laurion, or Laurium, is a promontory in southwest Attica, Greece, projecting into the Egean sea, and is celebrated for its lead mines, which have been worked since prehistoric times.

The mines are supposed to have been operated first by the Pœnicians in the sixth century B. C., and,

The largest company in this field is the Compagnie Française de Mines du Laurium, whose output in 1904 was over 250,000 tons.

The mixed sulphide ores of this district resemble those of Leadville, Colo. An average of this ore would be about 10% lead, 12% zinc and 15% iron in the form of pyrite in a gangue of quartz and calcite, which is generally mixed more or less with siderite and carbonates of manganese. The Soureza ores are chiefly galena (with some lead carbonate) and zinc carbonate in a gangue of calc spar and fluor spar—sometimes as much as 30% of the latter, with very little iron or silica. In bulk they run about 10% to 12% lead, with probably ten or twelve ounces silver to the ton.

The accompanying cut shows the latest type of large modern silver-lead furnace, recently ordered for this district. This furnace is 48x160 inches internal dimensions, and was built by the Colorado Iron Works Co. at their plant in Denver, Colo. It has a capacity of about 200 tons per day.

The mines of Laurium are about 50 miles from Athens, with which they are connected by rail through the port of Laurium or Ergasteria, and has a good harbor and a population of about 20,000.

## THE PROSPECTOR.

The samples from Jefferson county, Wash., are determined as follows: No. 1. The red ore is hematite (iron oxide). No. 2. The black ore is a siliceous rock containing considerable black oxide of manganese. No. 3 is a copper ore consisting of a granular rock containing several per cent of bornite (copper sulphide) and malachite, green copper carbonate. As these minerals occur in separate and distinct layers, but in the same vein or fissure, they apparently have some relation. The iron oxide is a common occurrence in the outcrop of copper veins and so also is manganese. Often where the latter is found associated with copper ores, silver, and sometimes gold, is also present.

The ore from Bisbee, Ariz., marked J. M. M., is bismuthinite (bismuth glance). When pure it contains sulphur 18.8%, bismuth 81.2%. The specimen contains considerable disseminated iron and copper sulphide, and in the gangue, silica, calcium carbonate and magnesia.

The mineral from Patagonia, Ariz., is pyrite (iron sulphides) and marcasite, with a few very small grains of copper sulphide. Arsenic is also present and shows in the yellowish stain along one side of the specimen, where the ore is slightly oxidized. There is some disseminated quartz. The ore may contain

Large Modern Silver-Lead Furnace.

with the growth of Athenian supremacy, they were of the greatest commercial value to the State. The chief product of the mines in the earlier periods of their working was silver, although large quantities of lead were obtained, and the yield of minium (red oxide of lead) was of appreciable value.

In 1860 a Marseilles company bought the right to work over the heaps of refuse, from which much lead was extracted. In 1869 a dispute arose over limitations imposed by the contract, and after a protracted lawsuit the company, in 1873, purchased a large tract of land.

Since then several companies have occupied the territory, and carry on profitable operations in the production of lead and kindred metals. Silver, the most important metal in ancient times, is, however, of little value at present.

gold and silver. The presence of the former should be detected by careful roasting, grinding in a mortar and panning, unless the gold is very fine. The best way is to have a sample assayed. It may be shipping ore for all that can be told by looking at it, while on the other hand such ore is often too low grade in precious metals to make its treatment profitable.

The white mineral specimen from El Dorado county, Cal., is a siliceous talc schist. It is probably the result of the alteration of a basic rock of some kind, impossible from the specimen to determine.

The rocks from Salt Lake City, Utah, marked E. C. D. M., are: 1. Garnet rock. 2. Dolomite. 3. Greenstone. 4. Calcium carbonate.

## Vertical Shaft Sinking on the Rand.

Written by H. FRASER ROCHE.

Shaft sinking by hand has fallen somewhat into disuse since the war, and this, I think, can be safely attributed to our labor troubles. The best sinking by hand labor was done at the Jupiter East shaft, prior to the war and the figures from there may be cited as an example of this method of sinking. This shaft was 28x8 feet, and was worked in three shifts of eight hours each, the number of boys employed on each shift being from forty to fifty. Each shift, when going on, cleaned out the ground broken by the one preceding it, and then commenced drilling double handed. The ground was carried in as many benches as possible, the top bench being often 20 feet above the sump, which was composed of a four-holed cut. When an average of 3 feet was reached in most of the holes, they were charged up and fired in the usual manner, the cut coming first. In one month 211 feet were sunk in this manner with buckets, and an average taken over ten months gave 165 feet per month. The conditions under which this sinking was accomplished were nearly perfect, the shaft being absolutely dry, the boys (Basutos) excellent, and the three contractors among the best miners to be found in this country. The timbering was done in the usual manner, and always kept within at least 30 feet of the bottom of the shaft. The total cost averaged approximately £20 per foot. The great influx of unskilled labor may probably cause many of our engineers to revert to hand labor wherever possible, as this is here the cheapest and most rapid

suitable and regular intervals. The proximity of the timber to the bottom of the shaft is of great value in rapidly removing the smoke and gas after blasting, since ventilating pipes can be carried down to the bottom set and connected with a fan at the bank-head. Till October, 1904, the South Nourse held the record for shaft sinking with machines.

Another method is that employed at the Village Deep, in the Western shaft. A double direct-acting engine, 250 H. P., is used with buckets. This engine has been augmented by a smaller geared hoist and bucket. The buckets run in crossheads with steel shoes on wooden runners. The tipping process with these buckets is far inferior to the skip method. The three center compartments are used for hoisting, the Eastern one for pump, air main and ladder way, and the remaining one kept clear. The sinking is carried on as follows:

Four bars are rigged—two of them 1 to 3 feet from the end of the shaft, and the other two 7 feet from each of these. Three 34-inch Ingersoll-Sergeant machines were used on each bar, each side machine drilling three holes, the center ones drilling three also, but sometimes one of these was omitted when the ground allowed. These were tended by eight white men with native helpers. The cut holes are drilled 10 feet deep, and the side 8 to 9 feet, all being started with star bits and completed with a succession of chisels, the average time taken during October for drilling being eight hours. All were then charged and blasted together, this blast generally breaking 4 feet of ground. Cleaning down the timbers could not be started for fully an hour afterwards, owing to the bad ventilation, and an hour and

bottom of the shaft. This gear was designed to carry 4-ton skips on 60-pound rails, 4 feet 4 inch gauge, with guide rails of same weight, 2 feet gauge. These rails are riveted on cast iron brackets, 6 feet centers and through bolted to the dividers. The distance pieces used were 9 inches by 2 inches. These rails have been placed in the Village Deep No. 1 shaft, and have been found highly satisfactory. Ten thousand three hundred feet of rails were placed in position in nine days.

On several occasions strong feeders of water were passed through and gave rise to a lot of trouble. These were dealt with by placing water rugs at the first timber set below the feeder, and then blocking the set as closely as possible to the sides of the shaft. Good strong clay was then tamped into the crevices, thus making a water-tight joint with the sides of the shaft. If necessary, the spaces between the studdles were raised 3 inches by means of closely fitting slats. The whole ring was then surfaced out and tamped with clay, and given a slight fall towards the pumping compartment, where a 2-inch pipe was placed in the ring, leading to a 600-gallon tank, which formed the sump for a suitably sized pump. A good deal of water was encountered in this shaft, it being found necessary to ring it at the 300, 600 and 800-foot levels, and air pumps were used in connection with tank sumps at these points, with a sinking pump always at the bottom. A big break with north and south strike dipping 80° east was met with 400 feet down, but left at 700 feet, and this gave rise to most of the water. At the 1000-foot level a big pumping station and sump were cut, the excavation amounting to over 700 cubic yards. The break was again encountered in the excavation and a strong timber and clay dam was built forming a sump of 50,000-gallon capacity. A Riedler air pump, 25 H. P., with reheater, was put down, with an electrical pump as a stand-by, and an 8-inch column takes all the water from here to the surface. At 1200 feet another large feeder of water was cut and successfully ringed, and led into a 600-gallon tank, which formed the sump of a 16-inch by 8-inch pump. At 2120 feet a similar station to that at 1000 feet is being cut for the reception of pumps. During the last six months an average of 3500 gallons of water per hour has been brought to the surface.

There are some interesting facts to be learned from the Cinderella Deep shaft. This was sunk mostly by machines, four only being used at one time, and the average monthly sinking during 1903 was 96½ feet. This shaft has been remarkable for the low consumption of dynamite, 0.602 pound per ton of rock hoisted, and the very low cost during that period, viz., £20 per foot. As this is the only shaft on the property, no other, I believe, being contemplated at present, a brattice wall is being carried down to overcome the difficulty of ventilation when developing and stoping commence. An excellent job is being made of this with pitch pine boards 1½ inch, tongued and grooved. The effect even now is highly satisfactory, all smoke and gas being out a quarter of an hour or twenty minutes after blasting.

An ideal method and gear for the sinking of future deep level vertical shafts I submit as follows: First, the permanent steel or wooden headgear to be used should be erected on suitable foundations. The first 100 to 150 feet of sinking would of necessity be slow, until the solid formation is properly entered. A few feet more according to its nature should be excavated in this, and the collar set definitely placed in position, and the first bearer set fixed in deeply seated hitches in the solid at the bottom, and the timber from the collar set to the bearers hung, close-lagged and blocked up.

One of the most important matters to my mind coming next is the tamping in of 20 to 30 feet good solid clay directly above the first set of bearers, and this should stop all surface water entering the shaft. In the meantime the permanent winding engines should have been laid down to be used in future sinking operations; and then we come to a vital question, whether skips or buckets are to be used. I think every one will agree with me in deciding at once for the former. They undoubtedly afford greater safety, quicker hauling, and better facilities for helping the pumps with the water, and I can confidently affirm that 20 feet more a month can be done with skips. The second and fourth compartments should be used for hauling, the first for a winch if necessary, the third kept idle, and the fifth for ladders, air and pump mains. The method of sinking will greatly depend on the quantity of water encountered. For a dry shaft hand labor, I believe, is the quickest, cheapest, and generally the most suitable. For a system, that employed at the Jupiter is excellent, but I would suggest the blasting of some of the end and side holes first, as I have found that the sump and easers will blast better and break more effectively when slightly loaded with the ground from the blasting of these holes. When water enters into the question I am sure machines will sink faster, as it is no longer possible to sink in benches.

Another matter which causes great difference of opinion is the number of machines which can be successfully and economically employed in a shaft of this size. The various experiments tried at the Village Deep make me a strong advocate of twelve. Over a period of a month we found a net gain of one hour per shift in the time of drilling by using twelve

Distribution of Drill Holes in Shaft on the Rand.

means of sinking, but to obtain a footage anything like the Jupiter it would be necessary to have picked hammer boys or Chinamen, and also fairly good ground and no water.

The sinking of vertical shafts by machines has many different phases, and my purpose is to try and strike an ideal system, in the hope that it may lead to beneficial discussion. Many different methods have been employed with varying success, and it will be best to take actual cases to demonstrate these.

The equipment of the South Nourse shaft is probably the best in use here to-day, their permanent winding engines and headgears having been erected. The engines are 1000 H. P. Whiting hoists, equipped with drums. The size of the shafts is 32x8 feet, divided into five compartments, three of which (the two end and center ones) are not used for hauling ground. The remaining two, Nos. 2 and 4, are fitted with 2-ton self-tipping skips, with steel shoes on wooden runners. One end compartment is used for pumps, air main, and ladder way, and the center one, being kept entirely free, greatly adds to the convenience of timbering, since it can always be staged.

Sinking operations are conducted as follows: Six small machines of 2½-inch diameter, on six bars, are in use, each tended by one white miner, with native or Chinese helpers. Forty to fifty holes from 4 to 5 feet in depth are drilled over the bottom of the shaft, their position, of course, depending on the state of the ground to be broken. These are then blasted, and cleaning begins as soon after as possible, the first skip of ground being hauled in from thirty to forty-five minutes. From ten to fourteen muckers are employed per shift, which varies in duration with the ground broken, but two shifts are usually sufficient for each round. The timber is similar to that ordinarily used in deep level shafts, viz., wall plates, dividers, end plates and studdles. The wall plates are mortised to receive the studdles and dividers, each divider effectually blocking two studdles at each end. The sets are blocked in the ordinary way with the sides of the shaft. The use of skips necessitates the timber being kept within 30 feet, or thereabouts, of the bottom of the shaft. The bottom wall plates are cleated with sheet iron to protect them against the blasting, but these are capable of rapid adjustment and removal.

Two sets of wall plates are lowered in quick succession beneath the skips, and the hanging is operated from the last blocked set and the bottom of the shaft. The runners (guides) are kept as close as possible to the bottom set in position, and below this temporary runners in 6-foot lengths are used, thus allowing the skips to reach the bottom without the shoes leaving the runners. Bearers are placed at

a half generally elapsed before the first bucket of ground was hauled. Eighteen muckers were employed per shift, and three shifts per round.

When the 4 feet referred to was cleaned up, the sumps of the old holes from the first blast were cleaned out by compressed air, and all charged again and blasted, after which similar cleaning operations were proceeded with. The average depth per round cleaned during October was 7.5 feet, twenty such rounds being drilled, blasted and cleaned up during the month. The average time per round during the month was 37.4 hours, 4200 tons of ground were hauled, and 0.96 pound of dynamite was used per ton of ground hauled. In all, 150 feet was sunk and timbered during October.

The Village Deep shaft was laid out to consist of a pump and ladderway compartment 6 feet 6 inches by 6 feet 6 inches, and four hoisting compartments 5 feet by 6 feet 6 inches inside timbers. The timber consisted of the usual wall plates 30 feet 4 inches by 9 inches by 9 inches, end plates 8 feet by 9 inches by 9 inches, sets 6 feet vertical centers, corner studdles 8 inches by 8 inches, other studdles 9 inches by 6 inches, and dividers 9 inches by 7 inches. All timber was pitch pine.

Owing to three center compartments being used for hauling, the blocking and fixing of dividers in position had mostly to be done while drilling operations were going on. Thirty feet of wall plates were hung on each side at a time—that is, ten wall plates were hung in succession. All wall plates were suspended from the rope of the center compartment (the bucket being first removed), lowered and swung in position by a rope at each end, and hung on four 1½-inch hanging bolts from the set above. The actual hanging of wall plates seems at first a difficult and dangerous operation, but with skilled timbermen great speed is attained, the average time per wall plate being five minutes. The hanging of the wall plates was always arranged to take place after the second blast, for the machines, bars and gear for drilling were lowered before the second cleanup was actually finished. The blocking of the sets, and placing studdles and dividers in position followed as soon as possible, and as the last timber set was completed, new wall plates were lowered. Wooden runners 8 inches by 4 inches in 30-foot lengths were used in the three winding compartments and were kept as close as possible to the bottom of the timbers. Sets of six single bearers were placed in suitable positions, at fairly regular intervals, of 80 feet, in deeply seated hitches, the end bearers being 14 inches by 9 inches, and the center 14 inches by 7 inches.

These being in position and sets blocked, the hanging bolts above the bearers were taken out. The timber was on an average 60 feet from the

machines instead of eight. Six white miners and twenty-four native helpers can successfully manipulate these and the plan of drilling should be somewhat as follows:

Holes Nos. 5, 13, 15, 22, 24, 32, may often be dispensed with, but that will entirely depend on the ground to be broken. In elevation the sumps of holes 16, 17, 18, should practically reach sumps of holes 19, 20, 21, and the sump of a hole such as 14 should be within 3 feet of the sump 17. If this is carried out no trouble will be experienced as regards blasting the timber. The blasting, cleaning, and timbering cannot be bettered at Village Deep. In almost all deep level mines of to-day water will probably be met with, if not in the shaft, in the future mining operations, and I would advocate at the time of sinking a Cornish pump being carried down as sinking operations are extended. The size of the pump would depend on the quantity of water estimated by the surrounding conditions and data from outcrop mines. It will be necessary to cut sumps about 300 feet vertically, and place balance bobs about every 500 feet. In conjunction with this pump a sinking pump of sufficient size to deal with the water encountered would be carried down with the sinking.

The lighting of a sinking shaft should be done as at

### The Bessemerizing of Copper Mattes.

Sulphide copper ores were concentrated into mattes for many years before the refining of the matte was undertaken in converters. Metallurgists had already conceived the idea of desulphurizing mattes by blowing air into the molten mass long before Mr. Bessemer's idea became a success. The conversion of mattes was first suggested in 1866 in Germany. In the same year a patent was taken out in the United States to convert copper matte by the Bessemer process of steel making. In the early experiments there was no trouble with the process until a large percentage of sulphur was oxidized and copper began to separate, when the tuyeres became clogged. Improvements were made, and step by step the process was perfected. It is stated that the Japanese metallurgists have for centuries made a good grade of copper in two operations—first, smelting to matte; second, blowing to a good grade of copper in a converter. This process is described in a report of the Director of the Mining Bureau of Japan, issued 1893. As the success of the idea developed, the necessary changes were made in the form and size of converters. The air was introduced at a higher point in the side through a hollow trun-

and protects the matte, may explain the anomaly.

Though it is difficult to see why finely divided silica ascending through the charge should not be attacked in preference to silica embedded in the lining, nevertheless results of experiments prove that the silica, whose specific gravity is so much less than that of the matte, does in great measure escape unaltered, and that the lining is the only economical menstruum for its supply. The practice has generally been to make the lining as siliceous as possible, using a pure quartz or quartzite mixed with only clay sufficient to make a plastic mass capable of being hand-moulded into lumps, which are generally pounded, also by hand, into the converter. Where the lining is not mechanically pressed into the converters, and the grade of the matte not above 50%, about one-half, often somewhat more, of the weight of lining is consumed to the weight of copper pigs made. At the Great Falls plant the lining is mechanically pounded into place by a steel tamper around a steel templet, which is expanded by a wedge while the lining is being inserted, and can be made to collapse sufficiently for extraction by the removal of the wedge after the lining is thoroughly set. The converter during the tamping rests on a revolving table. In this way the mass is more uniformly compacted, leakage of blast between the lining and the shell, or through

Copper Converters at Cananea, Mexico.

Cinderella and Village Deeps—that is, by two clusters of electric lamps 32 C. P., four to six lamps in each cluster, and suspended from the timbers.

I do not care for ventilating pipes, but would rather have a brattice wall as put in at Cinderella Deep. The cost of such is approximately 10s. per foot.

The matter of comparing costs of different shafts is a very difficult one, owing to the many diverse ways in which the various items of expenditure are grouped, and I cannot remember having ever come across the costs of two shafts which had been kept in exactly the same way, and gave the same information. The cost of a shaft sunk by hand should be somewhere in the region of £20 and by machines about £30 per foot, but these figures must naturally vary very much, as the whole matter practically depends on what amount of water has to be dealt with.

THE discovery of a vein or ore deposit gives the discoverer no right to the mineral so discovered if no steps are taken to appropriate the same as required by law. The reverse is often the case—that is, the locator claims ground and stakes it before a bona fide discovery has actually been made. In some instances this is done from necessity, as in a case where the mineral is buried under debris or a later geological formation.

nion instead of at the bottom. A wind box was provided through which the tuyeres could be punched and kept clear. The several steps in blowing matte into metallic copper are as follows: The lining of the converter with silica and clay. This is done to protect the walls of the converter, and also to supply the necessary silica to combine with the iron to aid in the operation. Charging the converter from the blast furnace. First blow, followed by skimming of the charge; second blow, with frequent punching; final skimming; pouring of the separated metal; repairing the lining; disposal of the slag.

As no practical method has been devised for adding silica to the charge, except through the medium of the lining, the constitution of the lining and the mode of building it into the shell are matters of extreme importance. Attempts have been made to blow the silica into the charge through the tuyeres, and to satisfy the matte by throwing it as lumps into the converter mouth; but apart from mechanical difficulties attending these methods, the silica remains too short a time in contact with the matte to permit of its combination with the oxidized iron, and therefore, whether added in powder or in coarse particles, most of it is found floating, unaltered, in the slag. The violent agitation of the converter's contents, and the rapidity with which the reactions take place, and the large body of slag which is almost immediately formed

the porous lining, is minimized, a larger amount of material is compressed into a given space, and the surface is smoother and less liable to abrasion than in the hand-made lining. As a result, a single lining lasts more than twice as many charges than when it is hand-laid, which is partly due, however, to its greater thickness. Usually with a 45% to 50% matte not more than four charges can be tapped to a lining, and between each charge more or less patching is done through the mouth of the converter. The patching can be more easily effected in the shallow trough or barrel converter than in the deep vertical shell. It has been found, however, that a much more basic lining can be used without retarding the final reduction to metal, and that the presence of copper is not detrimental.

The accompanying illustration is that of the converting plant at Cananea, Mexico.

The actual business of blowing a charge of matte is one requiring skill and experience on the part of the operator, who is known as the skimmer. The art can be learned only by actual practice. The attendant must learn to determine the condition of the charge by the color of the flames at the nose of the converter. The first blow usually lasts from forty to sixty minutes, sometimes longer. In the first stages the color of the flame is green, with tinges of yellow. Later the flames assume a greenish blue, and finally

a blue color, if the blowing be continued. At this stage the converter is turned down and blowing discontinued, or the entire contents of the converter is likely to be blown out and scattered over the workmen and the building. This is caused by the rapid formation of a large volume of sulphurous gas. It is frequently necessary to skim the charge twice in order to remove the slag formed, and thus relieve the burden on the blast. The men in charge of converters become very expert and careful in the work and seldom overflow a charge, for in such unfortunate event they not only are in danger of reprimand from the superintendent, but are subjected to the ridicule of their associates.

### Jeffrey Endless Trough Conveyor.

Two illustrations are given herewith of the Jeffrey endless traveling trough conveyor at the mines of the

Prospective View of the Jeffrey Conveyor.

Big Sandy Coal & Coke Co., Marytown, W. Va. The conveyor travels 155 feet on an angle of  $37\frac{1}{2}^\circ$ ; for 87 feet at an angle of  $32^\circ$ , and 176 feet horizontally, describing a curve when it runs from the incline to the horizontal. The conveyor is 42 inches wide, 8

Jeffrey Conveyor at Big Sandy C. & C. Co., Marytown, W. Va.\*

inches deep, and travels at the rate of 100 feet per minute. When fed continually it has a capacity of 3000 tons per day.

It is constructed of two strands of 18-inch pitch steel thimble roller chain, provided with self-oiling flanged rollers, the chain having attachments at one

side to which double-beaded or corrugated plates are bolted. These plates are provided with corrugations something on the order of corrugated roofing.

The corrugations overlap each other at the joints, forming a tight apron or belt, which will not open in any position, whether traveling horizontally or on a curve, or around the wheels at the end. To prevent the coal falling off at the sides, end or side pieces are provided which are 8 inches high and overlap each other, shingle fashion; thus it will be seen that we have a traveling trough that carries the coal without friction. Furthermore, the conveyor, being on rollers, will operate with a minimum of friction, wear and consumption of power. The coal is delivered to the conveyor at the top, from a bin, the conveyor acting as an automatic feeder, so that no special feeding device is required. It discharges its load at the bottom onto a set of screens for loading into railroad cars.

### Precipitation of Gold and Silver From Cyanide Solutions.\*

NUMBER II.

Written by W. J. SHARWOOD.

The Siemens-Halske process consists in precipitating the gold and silver by the electric current, the solution being passed in a continuous stream through a large tank divided into several compartments, each of which contains a number of large sheets of metal forming the electrodes. Originally the anodes were of sheet iron, and the cathodes on which the gold deposited were of thin sheet lead. When a sufficient amount of metal had collected the lead sheets were melted and refined. The more recent plan is to have the anodes of lead coated with lead peroxide (which is not attacked by cyanide as the iron was), and the cathodes of tinned iron. The gold deposits on this in a finely divided condition and collects in the bottom of the tank, from which it is removed at intervals, the metal sheets being permanent. From 6% to 12% of the theoretical precipitating efficiency of the current is said to be obtained in practice.

The electrolytic system has the advantage of precipitating copper out of the solution, and as each pound of copper keeps from three to four pounds of cyanide in an inactive condition, as regards dissolving gold or silver, the removal of this metal regenerates a considerable amount of the cyanide.

Precipitation with aluminum removes gold and silver, but the metal has a tendency to oxidize, is more expensive than zinc and has not come into practical use.

Precipitation with sodium, in the form of amalgam, has several theoretical advantages over zinc. When the sodium replaces the gold in the solutions it regenerates the cyanide, a certain amount of caustic soda is also formed which helps to keep up the alkali in the solution. The difficulty in using it appears to be mainly in getting a sufficiently large surface of sodium amalgam in contact with the solution, when large tonnages of solution are to be precipitated. The amalgam may be made by addition of metallic sodium, or more cheaply by electrolyzing common salt or sodium carbonate with a mercury cathode.

Zinc shavings have been and continue to be used at most plants, the solution running in a continuous stream through the boxes containing them. On the whole they have proved satisfactory, when the attempt has not been made to crowd too much solution

rule the latter condition is prevented by having more free cyanide or free alkali present, and dipping the shavings into lead acetate before use gives them a coating of lead which sets up galvanic action and aids precipitation.

The use of zinc dust or zinc fume has not, I believe, so far been introduced at any of the California mills operating cyanide plants. It is, however, employed at several of the largest plants in other Western States. Zinc dust or fume is a product obtained in reducing zinc from its ores; as the metal is distilled from the retorts, a certain proportion condenses in the form of a powder consisting of very minute globules of metal coated with oxide. Owing to the fineness of its particles, this material exposes a very large surface and is well adapted for use as a precipitating agent. The method of employing it at the larger plants is to collect the solution flowing from the sand vats in two or more tanks; when one of these is full it is agitated for a few minutes, and a suitable quantity of the dust is introduced, either by scattering it in a dry form on the surface or spraying it in as an emulsion; the mixture is then forced by a pump through a filter press, from which the barren liquid flows to the storage tanks, while the precipitated metals and any excess of zinc are retained in the press until the cleanup. The percentage of cyanide having been determined before precipitating, the proper weight of cyanide to bring a tankful up to working strength can be calculated and placed in the launder leading from the press, where it is dissolved by the flowing solution. The zinc dust and precipitate form a porous mass, which offers very little resistance to the passage of solution, and the pressure in the press is very slight if the liquors precipitated are clear, so that the chambers or frames may be proportioned to form cakes several inches thick. If, however, the solutions carry suspended slime, such as sometimes forms when solutions differing greatly in alkalinity are allowed to mix, there is a tendency to clog the filter cloths and increase the pressure on the pump, which may rise under extreme conditions to thirty pounds or more per square inch. Any suitable form of force pump may be used, such as a direct-acting steam pump of the duplex type, or a belt driven pump of two or more cylinders so as to give a uniform flow of solution. Any tendency of the precipitate to clog the cylinders is prevented by washing them out with a little clear solution after each pumping.

As the solutions have to be pumped up to the storage tanks, whatever method of precipitation is adopted, there is not a very great increase with this system in the power required; for instance, if the average pressure in the press is as high as ten pounds per square inch, this is equivalent to pumping the solution 23 feet higher; on the other hand, the fall due to the "gold tanks" and zinc boxes of an ordinary plant is saved, say, 8 to 10 feet, which makes only 13 to 15 feet average head in excess of what would be required with a zinc shaving plant, as the precipitating tanks take the place of the "sumps" and all intermediate tanks are omitted.

From one-sixth to one-third pound of zinc dust is used per ton of solution, while about six tons per hour can be passed through every hundred square feet of filter cloth in the press. In some plants the coarser portion of the zinc and precipitate is allowed to settle at the bottom of the precipitating vat and accumulate until the cleanup. In others it is stirred up when the tank has been pumped nearly empty, so that all is collected in the press. The latter practice seems to be the better, as, while the greater part of the gold is precipitated by simply stirring while the dust is suspended, precipitation is completed while the solution is filtering through the undissolved zinc in the chambers of the press. For this reason it is also usual to add a larger proportion of zinc in the first few tanks pumped after a cleanup. At the end of a run, lasting from two weeks to two months, the contents of the press are washed by pumping a little water, partially dried by blowing air through them and then removed. Most of the cake falls out readily when the press is opened and the frames moved. At this stage the product usually carries about one-third its weight of water. Its composition does not differ materially from that of zinc shavings precipitate, and it may be refined in the same way. It is, however, more uniform, owing to the absence of threads of "short zinc." The blowing operation oxidizes some of the undissolved zinc and sometimes causes the presses to become warm. During precipitation a certain amount of hydrogen is evolved, and its formation continues slowly, while the precipitate stands in a moist state. Care must, therefore, be taken to bring no naked lights near when inspecting valves, etc., at the time of the cleanup.

Zinc dust is shipped in drums and barrels holding from 800 to 1600 pounds. The price is lower than that of cut shavings and slightly higher than that of sheet zinc. It is not uniform in composition, but generally contains over 90% of metallic zinc. The presence of a small percentage of lead has been found very advantageous in effecting thorough precipitation. The fineness of division also varies, but in good samples over 95% will pass a screen of 200 meshes to the linear inch, while most of the particles are shown by the microscope to be not over  $\frac{1}{1000}$  inch in diameter.

(TO BE CONTINUED.)

\* Abstract Trans. Cal. Min. Assn.

## Mining and Metallurgical Patents.

PATENTS ISSUED APRIL 25, 1905.

Specially Reported and Illustrated for the MINING AND SCIENTIFIC PRESS.

CONTROLLER FOR PNEUMATIC COMPRESSORS.—No. 787,489; B. F. Bergh, New York, N. Y.

In pneumatic pump controller, combination of motor-controlling vibratory member subjected to reservoir pressure, single spring opposing pressure, means normally restraining member against movement under reservoir pressure, and releasing device for means and actuated by reservoir pressure of pre-determined degree whereby vibratory member is actuated by difference in pressure between that of reservoir pressure and spring pressure.

ORE CRUSHER.—No. 787,604; F. E. Woodbury, Milwaukee, Wis.

Combination with ore crusher comprising receptacle in which ore is crushed, means for crushing ore and grate through which pulp is discharged, of catch box having opening into receptacle inside of grate, opening below provided with screen, and means for producing upward pulsating current of water through screen and catch box into receptacle.

PNEUMATICALLY ACTUATED TOOL.—No. 787,961; R. Temple, Denver, Colo.

Mechanisms of class described, combination of pulsating engine cylinder, piston mechanism movably mounted therein, tool cylinder, piston mechanism reciprocatingly mounted therein and dividing tool cylinder into two chambers, tubular mechanism connecting chambers of tool cylinder and pulsating engine cylinder together, passage connecting both chambers

of tool cylinder together, check valve mechanism in such passage, and manually operable controlling valve for throwing check valve mechanism into and out of operative position.

LEACHING APPARATUS.—No. 787,902; C. E. Dewey, Denver, Colo.

In leaching apparatus, combination of tank V-shaped in cross-section, and lead conduit located in bottom of tank and provided with vertically disposed orificed nozzles, nozzles being of sufficient length to cause fluid introduced into conduit to be carried upwardly into tank in vertical jets or streams.

FLASH TESTER.—No. 788,250; F. A. Courtois, Newark, N. J.

Flash tester comprising support, heater arranged underneath support, flue on support, test cup removably placed in flue and having trough around upper portion, burner tip for extending over test cup, and thermometer support.

PRECIPITATION PROCESS.—No. 788,443; G. H. Waterbury, Denver, Colo.

Process of precipitating copper in solution, consisting in placing solution in tank or receptacle containing pieces of aluminum of shape to allow solution to pass readily therethrough, and introducing air and steam simultaneously for agitating purposes.

CRUSHING MACHINE.—No. 788,207; T. J. Gray, Chicago, Ill.

Crushing machine comprising stationary jaw; reciprocating jaw having rearwardly extending arm rigid therewith; pair of swinging links H pivotally supported at upper ends and attached at lower ends to transverse shaft 7 upon which reciprocating jaw is pivotally supported; pitman with which arm of reciprocating jaw has jointed connection; pair of swinging tension rods having jointed connection with pitman and tied to swing about axis forward of reciprocating crushing jaw; and spring tension rod providing yielding spring connection between pitman and reciprocating crushing jaw and arranged parallel or substantially parallel with right line extending forward from connection between jaw arm and pitman and intersecting reciprocating jaw at point between axis of pivot shaft 7 and axis about which suspending links swing, connection between jaw arm and pitman being at point between axis of pivotal or jointed connection between tension rods K and pitman, and axis about which pitman operates.

COMBINED DREDGER AND MINING SLUICE.—No. 788,211; C. H. Lewis, Baltimore, Md.

Dredger and mining sluice, which comprises rotatable vessel provided at or near forward end, with series of angularly placed and projecting scoops in communication with interior of vessel, and having at rear end outlet opening, together with appliances whereby device may be drawn along bed of sand beneath water.

DUMPING CAR.—No. 788,096; A. W. Dahmer, Sonora, Cal.

Opening, closing and locking device for door of dumping cars, device comprising lever fulcrumed to side of car so as to provide long and short arm, link connecting long arm of lever with hinged door, and a second link connecting short arm of lever with fulcrum fixed with relation to car.

## MINING SUMMARY.

Specially Compiled and Reported for the MINING AND SCIENTIFIC PRESS.

Dr. J. H. Pratt's annual report to the United States Geological Survey on the production of asbestos shows that the principal changes to be noted in the asbestos industry at the close of 1904 were the increase in the production in the United States of the amphibole variety, the development of the Grand Canyon chrysotile asbestos deposits and the increase in the demand for the chrysotile variety. The many new uses which have been devised for chrysotile asbestos have created a demand for it that is now in excess of the supply. The high price which can be obtained for the chrysotile asbestos when it is in fibers of sufficient length for spinning permits the mining of this mineral in some places where the cost of mining would become prohibitory with any material decrease in price. G. F. Sevor of New York City, for the Keashey & Mattison Co., has made tests on asbestos building lumber and magnesite building lumber and shows conclusively that both these materials are superior to wood for the purposes for which they are manufactured, but that the asbestos lumber is much better than the magnesite. Such asbestos lumber, when employed in the construction of street railway and standard railway cars, for covering the end framing, should prevent the cars from taking fire by any derangement of the electrical apparatus. Another type of asbestos building material that is beginning to be extensively used is asbestos board or sheathing for roofing and for side walls. An asbestos shingle recently patented by Messrs. Keashey and Mattison is composed of asbestos fiber and hydraulic cement. These shingles are much stronger than slate and lighter in weight. They are made in three colors—gray, slate and tile red—in squares  $\frac{1}{2}$  inches on a side, with two corners of the square truncated. Nearly all of the asbestos mined in the United States is of the amphibole variety, which is obtained from near New Hartford, Conn., from Sall mountain, Georgia, and from near Bedford City, Bedford county, Va. Small quantities of chrysotile asbestos have been mined at Dalton, Mass., and in the Grand Canyon, Ariz. No new deposits were reported in 1904, and all the mining and development work was confined to the known localities. The production of asbestos in the United States in 1904 was considerably in excess of that of 1903, and was obtained principally from the deposits in Georgia and Virginia, a small amount coming from Massachusetts. The total quantity amounted to 1480 short tons, valued at \$25,740, an average value of about \$17.40 per ton. This production is an increase of 593 tons in quantity and of \$8980 in value, as compared with that of 1903, which amounted to 887 short tons, valued at \$16,760.

### ALASKA.

Navigation between lower Lebarge and Dawson opened May 1, when a large scow left Lebarge for Dawson with freight. The scow will follow the outgoing ice down the river to Klondike. The ice is still firm on Lake Lebarge and many outfits of seasonal merchandise are being hurried across the lake to reach Dawson ahead of the freight shipped from White Horse. Vessels cannot run from White Horse until Lebarge opens, which will be about June 1.

Prospective building of the Alaska-Perseverance's big stamp mill in Silver Bow basin has had a stimulating influence upon mining in this district. It is said that but 100 stamps are to be erected at once, and that 200 will be added at a later date. A crosscut has been driven 2500 feet from a level above the sea and  $\frac{3}{4}$  miles from the shore, attaining a vertical depth of 1500 feet. No raise has been made through to the surface. It is said that the last 1400 feet of the crosscut is in a mineralized body of low-grade milling rock. On Douglas island the lode has been opened to a depth of more than 1000 feet, and has been mined along its course for considerable distance. In the glory hole workings there has been removed one block of ore 1500 feet long by 500 feet wide, and the glory hole is now down 250 to 300 feet.

### ARIZONA.

#### Gila County.

Adolph Lund of Chicago, representing the purchasers of the United States group of claims on the west side of Pinal creek, near Globe, has given contract for sinking the three-compartment shaft 100 feet farther. He expects to put in a hoisting plant.

#### Mohave County.

At Cerbat the St. Louis tunnel is in 250 feet.—The Tennessee and Schuykill mines at Chloride are to be unwatered.—E. S. Osborne of Bill Williams Fork reports a large force at work on his Mineral Dome group of mines. The new railroad from Congress has reached Cunningham Pass, 20 miles east of the Mineral Dome properties, and track is being laid at the rate of  $\frac{1}{4}$  mile daily. The survey runs within a few hundred yards of the property and it is expected to be completed to that point before the first of June.—F. Dunham has bonded the Fay property, south of Kingman.

#### Pinal County.

Sinking has been resumed at the Buckeye shaft of the Troy-Manhattan M. Co. at Troy. It will be carried from the 200 to the 500-foot level.

#### Yavapai County.

At the Pickaway properties, Turkey creek, being worked by the Yavapai Development Co., E. A. Haggott, superintendent, twenty men are employed; the shaft is down 300 feet and will be sunk 700 feet before any drifting is done. A new road from Turkey creek to Richenbar has been built, over which supplies are being hauled. These supplies were formerly hauled from Mayer, 22 miles distant. The new haul is 12 miles.—At the Great Republic, Turkey creek, Superintendent

Sullivan has twelve men at work, has his shaft down 500 feet and is sinking to the 700-foot level.—Near Skull valley, M. Murphy has the El Dorado M. Co.'s shaft down 100 feet and will continue it to the 200-foot level.

It is reported that C. J. McNulty and G. Waddell have resumed work on the R. A. M. mines on Little Copper creek, 12 miles south of Prescott.

J. K. Millor is putting up a 3-stamp sampling mill on his property near Hillside, Ariz.

At the Sterling mine, Big Bug district, pumps are clearing the mine of accumulated water and development work will be taken up. The main shaft is down 410 feet and drifts have been run both ways on the ore.

The air drills have started up in the Senator tunnel, near Prescott, and three eight-hour shifts are at work.

A whim is being placed on the Rawhide group, in Grapevine district.

### CALIFORNIA.

#### Amador County.

The new hoist at the Zeile is almost finished. It is reported that the ore body is reaching into the Fleming ground, in which case a new shaft will be necessary.

Grading has been started at the Climax mine, east of Jackson, for a 10-stamp mill. The 2-stamp mill has been idle for some time, and no further crushing of ore will likely be done until the new mill gets in operation. The new stamps are to be of 1000 pounds.

#### Calaveras County.

The Turkey Gulch M. Co. plan to construct a gold dredger to be placed in the Calaveras river near Jenny Lind.—It is reported that the main shaft at the Gwin mine is to be sunk 200 feet deeper.

#### El Dorado County.

At the Lone Star mine, near Smith's Flat, the main tunnel is in 1300 feet.—Work at the Granite mine, Smith's Flat district, is in charge of Chas. Henson. A new hoist is being put up.—The North Weber Land & Mining Co. are preparing to put a hoist on their gravel property near Newtown. Work in the shaft will be resumed as soon as the machinery is in place.

#### Mariposa County.

S. L. Brown, manager of the Tennessee & California G. M. Co., has men at work at the Mallet mine on Bear creek, near Mariposa.

#### Mendocino County.

The Eel river coal mine, 6 miles from Covelo, is being opened up.

#### Mono County.

The Golden Gate mines, in Antelope valley, 60 miles southwest of Carson, Nev., have been bought by J. S. Parker, J. T. Borden, L. D. Folsom, J. E. Monroe, F. E. Fielding, J. E. Bray, P. Barnes, M. G. Womack and W. S. Wilhelm, all of Reno, Nev., who have incorporated as the Golden Gate M. Co. They intend to develop the property and place a modern mill upon it to mill the ore now blocked out.

#### Nevada County.

It is reported that a 4-stage centrifugal pump at the 2400-foot level of the North Star mine, near Grass Valley, is pumping 350 gallons per minute to a vertical height of 800 feet.—D. P. Stewart and Wm. Hogan have sold the Maryland quartz mine, above Washington, to the Sierra Madre Exploration Co. of San Francisco. Geo. Montgomery is interested. There is a 2-stamp mill on the mine and the ledge is worked by tunnel.—The Empire M. Co. of Grass Valley has granted the request of the Orleans and Sultana people and will continue selling water to both for milling purposes until they can establish a pipe line of their own. The Empire, which has been supplying the mines mentioned, will require all the water its own pipe line will carry, as it intends to operate steam pumps. Recently it gave notice that it could not supply water later than May 1. This action, had it been strictly adhered to, would have caused a complete shutdown on Oshorn hill.—The Orleans hoist, which has been run by water, will be changed so that an oil burner may be put in.

J. W. Phelps has bonded 800 acres in Penn Valley, 10 miles from Nevada City, and is having it prospected to see if it is suitable for dredging.

#### San Diego County.

Amblygonite, a lithia mineral, is found in quantity near Pala. All of the lepidolite produced in the United States for commercial purposes is obtained from the same neighborhood. There are two other localities in this country at which lepidolite has been found in considerable quantity, one near Banner and the other 7 miles east of Julian. No lepidolite was mined at either of these localities during 1904, and only the necessary assessment work was done. The greater part of the lepidolite that has been mined in this country has been exported, but nearly all of the spodumene has been utilized by home chemical manufacturers. There is an overproduction of lithium mineral for domestic consumption, and unless some new technical uses can be found for the lithium salts, such as use on a considerable scale for pyrotechnic purposes, there must be considerable decrease in both the demand for them and the price they bring. The quantity of lithium minerals produced in the United States during 1904 amounted to 577 short tons, valued at \$5155. This is a decrease of 578 short tons in quantity and of \$18,270 in value as compared with the production of 1155 short tons, valued at \$23,425, in 1903. Of this 1904 production the greater part was spodumene from South Dakota. Three different minerals are mined at the present time for their lithium contents—lepidolite and spodumene, both lithium silicates, and amblygonite, a lithium phosphate.

The Chula Vista Oil Co. is drilling for oil near Chula Vista, being down 1350 feet. M. J. Hermann is secretary.—At Julian the Los Angeles M. Co. are in 800 feet in the Warlock tunnel.

#### Sierra County.

J. H. Liddle has started work on the Wisconsin drift mine, near Forest City, in an effort to cut the channel.

#### Pumas County.

(Special Correspondence).—The Indian Valley mine, near Greenville, is opening up its tunnels preparatory to starting up the mill.—Dodge Bros. are putting three 5-stamp batteries on the Standard, near Greenville. The New York Mines Co. of Greenville is putting in an additional five stamps.

Greenville, May 1.

#### Shasta County.

J. T. Jensen has completed his 4-stamp mill on the Black Jack mine near Centerville.—J. Hulme intends to put in a 10-stamp mill and cyanide plant on the Crown Deep mine in the Lower Springs district, 3 miles west of Redding.—The owners of the Graham group of mines, B. A. Graham, P. F. Grant, H. Callaghan, J. D. Graham and W. Bassett, which are located on Horse mountain, in the Pittsburg mining district, midway between Copper City and Baird, have bonded the mines to P. Deidesheimer of San Francisco, Cal., for \$30,000.

#### Siskiyou County.

The Yreka Creek Gold Dredging Co. has commenced digging a basin for a new dredger at the Antone Foster place, on Yreka creek, 1 mile north of Yreka. The company will probably open up the Solus place above Hawkinsville at mouth of Yreka creek also, and fix up the old dredger for renewing operations. W. H. Estabrook is the superintending manager and W. L. Cooper has been employed as foreman.

#### Tuolumne County.

A duplex air compressor has been put in at the Souldy mine at Souldyville preparatory to sinking the shaft deeper.—It is reported that the 10-stamp mill of the Clio mine, near Jacksonville, has been temporarily closed.—The Santa Ysabel shaft, near Stent, is down 800 feet.—Pumping machinery has been put in at W. Lewis' Red Hill mine at Bald mountain preparatory to working.—Ore from the Sell mine, near Sonora, is being crushed in the Hope mill.—The Mohican mine, near Tuolumne, has been started after an enforced idleness of several weeks for lack of fuel.—Sinking has been resumed in the new Calico mine at Stent. The shaft will be sunk to a depth of 300 feet, when drifting will be started.—Work has been commenced on the Crescent mine on the South Fork of the Stanislaus river, owned by W. Prange and R. L. Potter.

### COLORADO.

(Special Correspondence).—The output in several of the mining districts of the State have been curtailed the past month owing to storms in the mountains and the bad condition of the roads leading to the different mines. In many places the roads are practically impassable owing to the heavy snow fall. This month will undoubtedly see a change for the better.—Governor McDonald has appointed A. W. Hogle, E. L. White and Eugene Grubb as a commission to represent Colorado at the Portland Exposition. Mr. White, who is commissioner of mines for Colorado, will have charge of the mining exhibit.—Several damage suits, aggregating thousands of dollars, have been filed in the Federal court by different mining and reduction companies against the Western Federation of Miners and its officials. These suits are the outcome of the strike in this State which was ordered by the Federation. The Federation officials and individual members of the order now have suits pending against ex-Governor Peabody and mine owners for damages for throwing some in jail and deporting others.—In Cripple Creek "high grading" has been carried on systematically in several of the high-grade mines, and it has been impossible to convict any one of the charges, even when they confessed to the crime of stealing the ore. One judge held some time ago that a miner taking the ore could not be convicted of stealing, as it was impossible to steal real estate. The latest report comes from Silverton, where they have caught several men with the ore in their possession. In some instances assayers act as a fence to dispose of the stolen ore. In places the men will be employed in one mine during the day and work in some other at night, for the sole purpose, it is stated by prominent mine operators, of high grading.—Injunction proceedings have been instituted in the United States Circuit Court against the Moffat road from entering or passing through Gore canyon, near Kremling, in Grand county. A company intending to use the canyon for an irrigating canal are the plaintiffs in the case.—The railroad from Sunset to Ward, in Boulder county, has resumed operations. This portion of the Colorado & Northwestern, operating out of Ward, has been abandoned for several months past on account of snow.

Denver, May 2.

#### Clear Creek County.

The 250-ton Newton annex mill, at Idaho Springs, has been started on the ores from the Gem mine. A 9x15 Blake crusher, two 14x26 rolls, four three-compartment and two two-compartment jigs, four Wilfley tables and three Wilfley slimers, and a full system of hydraulic sizers, classifying and settling tanks, have been added. The recrushing is done by a battery of 20 1000-pound rapid-drop stamps. The other section of the mill, which will be used for the concentration of ores which will run from eight to twelve tons into one, is equipped with 20 rapid-drop stamps crushing to 30-mesh, and three sets of Wilfley tables and slimers. Another section consists of ten slow-drop stamps, and has a complete equipment for amalgamation.—The 12th, 14th, 17th and 18th levels from the Gem shaft are being driven both east and west with machine drills, and it is largely the ore taken out in driving these levels which will keep the mill supplied for the present. The old Newton mill will treat custom ore. At present it is running almost entirely upon ores from the Sun and Moon mine.—The Alpine mill, at Idaho Springs, which has been lying idle for the past two months on account of legal entanglements, is said to have been started up on custom ores. It is understood that the mill will handle the entire output of the old Pewabic mine in Russell gulch, which will be shipped by way of the Gilpin tramway and the Colorado & Southern cars.—Lundstrom & Bue, leasing the Mint mine east of Empire, have found good smelting ore.—A good

strike is reported from the Ben Franklin on Silver mountain, belonging to F. Maxwell of Georgetown.

It is reported that parties are negotiating with the Aliunde Con. Co. of Georgetown for the privilege of handling the entire dump matter of the Equator, Ocean Wave and Marshall tunnels.

The upper Pay Rock tunnel, which is being driven to cut the Vulcan lode, near Georgetown, is expected to reach the vein during May. C. I. Burt, who holds the property under bond and lease, has charge.

It is stated that a new mill with a capacity of 100 tons daily will be erected at the base of Saxon mountain, near Georgetown, by the Anglo-Saxon M. & D. Co., which recently secured the Saxon Extension mine. A gravity tramway has been completed from the Saxon Extension tunnel to the base of the mountain, a distance of 800 feet, with a daily capacity of 100 tons. The mill will be amalgamation-concentration and is to have a cyanide annex. J. L. Crump of St. Paul, Minn., is secretary of the Anglo-Saxon Co. D. W. Shepard is manager at Georgetown. The property is being developed by tunnel.

#### Chaffee County.

The northern extension of the Dolomite group, near Newitt, 22 miles northeast of Buena Vista, is to be operated by the Tewen M. Co., who will put in machinery of sufficient capacity to insure rapid progress. A shaft will crosscut the ore shoot at an estimated depth of 300 feet.

#### Custer County.

The Fassett Brothers, who are developing the Walk-away, near Silver Cliff, expect to start shipping soon.—The Little Bernice Co. of Silver Cliff is shipping ore from the winze being sunk at the 280-foot level.

G. White of the P. & O. Co. has commenced driving the Brown tunnel, near Silver Cliff. The tunnel is in 150 feet, but will be widened and heightened. The ore in the higher workings is of a milling character.—The steam hoisting plant of the Robert E. Lee has been placed in the Invincible mine, near Silver Cliff, the shaft having been retimbered near the top of the collar, preparatory for more extensive work.—M. Moore and associates have a clear title to the California mine, near Silver Cliff, and will develop it.

#### Gilpin County.

(Special Correspondence).—Gilpin county still preserves the old method of measuring the loads of ore by the cord, which forty years ago was introduced for want of scales for weighing the ores, and for that reason they used the cord wood measure, or 128 cubic feet to the cord, holding eight tons of ore, more or less, according to the specific gravity. Most of the mills use the slow-drop stamps, plates and the humper for concentrating the ores of the district. Some of the mills are employing rapid-drop stamps. The milling industry has been retarded owing to the low treatment charges at the smelters, as the miners are able to ship direct to the smelters and get the full assay value of their ore. As a result of these low treatment charges being made by the smelters, some of the mills have closed down indefinitely and others have been obliged to close down a portion of their plant. Considerable ore is being shipped to the mills at Idaho Springs in Clear Creek county, owing perhaps to a better treatment charge that is being made at the Black Hawk mills. A large number of smaller properties are beginning to ship that heretofore were unable to make pay.—On Central City hill, J. B. Hafer & Co. are operating the Gregory No. 2. An adit is being driven on the vein. The company intend driving this tunnel 600 feet, which will give them 260 feet depth. The shaft on the Maine-Hamlet near by is down 400 feet and taking out ore. Drifting is being pushed in both directions from the shaft.—On Gregory hill, the Ontario-Colorado mine, H. Bowden, superintendent, has a shaft down 870 feet. This mine is producing thirty tons of mill dirt per day.—It is understood a number of the properties here are desirous of erecting their own reduction works, but are unable to secure a water supply sufficient to operate the mills.—A suit is pending between Central City and Black Hawk over the water supply of Nevada creek. Should Central City win the case, it is stated the mines in that vicinity would be in a position to secure water from the city. It is contended by Central City that the town of Black Hawk does not require the water for domestic purposes, while Central City is dependent on the stream for domestic use.—The Rocky Mountain concentrator, under the management of E. S. Moulton, has made some changes in the milling practice. Concentrators of their own design have been installed and they are doing good work. It is handling seventy tons of ore per day and is operated as a custom mill.—In Nevada gulch, A. M. Rucker is operating the Pozo. The ore is zinc, carrying some copper, gold and silver.—In the Russell Gulch district the Twolon M. Co. are hoisting twelve to fifteen tons of ore per day. The shaft is down 350 feet. Drifts are being run each direction on the vein from the shaft. J. H. Tuckfield is foreman.—The East Boston, between Central City and Black Hawk, is under the management of S. Hoskins. Drifts are being run to connect the Rialto and the East Boston—both properties being under one management. Wm. Job is superintendent of the East Boston Co.—The Hidden Treasure mill, under the management of W. J. Lewis, is operating twenty-five out of eighty-five stamps at present. Preparations are being made to operate fifty stamps, but on account of the condition of the roads they have been unable to get the ore.—The Old Town mine, in Russell gulch, which is developed to a depth of 1500 feet, is under the management of Geo. Kimball, Jr. This mine is now on a dividend-paying basis, and is fitted up with compressor, hoist, etc. The electric power is furnished by the electric company at Georgetown, 15 miles distant. Some of the ore from this mine is shipped to Idaho Springs for treatment in the mills at that point. A portion of the ore is treated in the mills at Black Hawk.

Central City, May 1.

The St. Louis 5-stamp mill in Lump gulch, near Gilpin, has been sold by G. D. Kaye of Boulder to Duffield et al. of Rollinsville, representing the Mountain Monarch M. Co. and Augustus & Sarchalotto of the Colorado property. A contract has been given to tear down the mill and equipment and set it up on the Mountain Mon-

arch millsite on Gambell gulch, in the Independent district, where it is proposed to double the capacity by putting in another battery of five stamps, bringing up the capacity to twenty-five tons per day. An independent company is to be formed for the operation of the mill. It will handle the product from the Mountain Monarch and Colorado properties, being connected with the latter by a tramway, which will be built at a later date.—Operations have been resumed at the Wood mine in Leavenworth gulch by Denison & Co., as lessees, and drifting work is being carried on in the 200-foot levels. As soon as the surface water abates the lessees intend to sink another lift in the main shaft so as to have ground for stoping purposes. They are figuring on the installation of a larger plant of machinery, including hoist and boiler. J. W. Cannon of Nevada is in charge.—Operations have been resumed at the New-foundland mine on Gunnell hill, west of Central City, by the Newfoundland G. & S. M. Co., with G. W. Mabee, Jr., as superintendent.

#### Gunnison County.

The Sunlight G. M. Co. has run its crosscut tunnel at Sherrod 200 feet. It is intended to cut the Golden Eagle at a depth of 400 feet. W. M. Bacon is secretary and treasurer.—It is reported that the Jersey Blue mill on Ohio creek has been started up.—A good strike is reported in the Raymond tunnel, near Ohio City, 1800 feet from the portal.—A. E. Reynolds, who recently took hold of the Gold Link group, a mile above the Raymond, is running another long tunnel, under the superintendency of J. F. Pearson. The tunnel is in nearly 1400 feet.

#### Hinsdale County.

J. A. Hunt has started work on the Silver Wedge tunnel,  $1\frac{1}{2}$  mile southeast of Lake City. It is in 400 feet and is to be continued 500 feet farther to intersect the Rob Roy shaft.

#### La Plata County.

(Special Correspondence).—The Empire M. Co., whose buildings were demolished by a snowslide in January, has opened the road to its property and has men at work building and repairing, and will resume operations on the crosscut tunnel as soon as buildings are up.—The new wagon road is being built from Durango to the Oro Fino district, where the Neglected and Durango Girl mines have heretofore been handicapped by the high cost of transportation. The Neglected is packing in supplies and will commence operations.—W. S. Bacon is at work near La Plata driving a crosscut tunnel to tap a large dike.—The Bonnie Girl at La Plata are finishing their 200-ton mill, which they expect to put in operation this season.—The May Day, near La Plata, has its wire ropeway in operation and is shipping twenty-five tons of high-grade ore per day. This mine has been equipped with electrical machinery to furnish lights and power for the Crane ore washer and small machinery, all of which is now in operation.—The Chief mine at La Plata has put in a gasoline engine and blower to ventilate the mine. The drift is in 400 feet; 300 more will be required to cut the vein.

La Plata, May 1.

#### Montezuma County.

(Special Correspondence).—All mining on the Mancos is at a standstill on account of the storms and snow in the higher mountains. Manager Franks, who was forced to close the Old Kentucky mine on account of lack of fuel, returned to Mancos recently to open the road and resume operations, but was forced by the late storms to delay the work and has returned to Cripple Creek for a month.—The old placer fields on the San Juan, 40 miles from Mancos, are being prospected with a view to the installation of dredgers.

Mancos, May 1.

#### San Juan County.

E. W. Walter, local manager for the Green Mountain M. & M. Co. at Silverton, expects the company's new 300-ton mill on the Green Mountain will be ready June 1. In the meantime the branch railroad from Howardsville to the millsite will be built and the mill equipment transported over the new line.—The Silverton Northern Railroad Co. are preparing to build a road up Cunningham gulch from their main line at Howardsville, and expect to have it running by July 1.

Manager W. R. Pyke of the Royal M. Co. has started men and machines on the Mazeppa drift and pushing work on the main drift in Sultan mountain, Silverton.—The new plant of the Hamlet M. Co. at Middleton is expected to be started by June 15.—A. A. Lamont, superintendent of the Yukon, or Uncle Sam property, on Cement creek, near Silverton, has been pushing work on the large vein recently cut by the crosscut tunnel.—The Kittimack M. Co., organized in Denver, to work the Minnie Gulch Co.'s mines, near Silverton, has had men doing assessment work on the claims and continuing development through two 900-foot tunnels that were run by the Minnie Gulch M. & T. Co., three years ago. The Kittimack Co. has secured a long term lease and bond from the principal stockholders of the Minnie Gulch M. & T. Co., and will operate in a systematic manner. F. S. Lavarack, superintendent for the Kittimack Co., will increase the present force to twenty-five or thirty.

Kunz & Hannum have started work on their Cashier-Dexter property, on Eureka mountain, near Silverton.—The Silver Lake mill, near Silverton, is to be changed by discarding Hallet tables and substituting No. 5 Wildcys. The change is considered by the management as desirable as regards close saving of the values in the ores, and it is said will involve the eight-hour day plan for the employees, irrespective of what department they are working in.—At Animas Forks on the Bagley tunnel, of the Frisco Mines Co., a combination air and electric drill is to be tried.

#### Summit County.

The Old Union M. & M. Co.'s main tunnel, near Breckenridge, above the millsite, makes an outlet for the ore now being mined from the stopes above it, and when connection is made with the upper workings on the top of Mineral hill, this tunnel will be the exit for all the mine products. The recent development in the mine tunnel has proved the existence of a ledge of ore 20 feet in width, all of which will pay to treat in the mill. This

tunnel will cut the shafts from the summit of Mineral hill at a depth of 450 feet. A. E. Keables is manager, G. C. Smith superintendent, F. Graham mill superintendent and D. H. Lawrence consulting engineer. The Union mill has been completed and Superintendent Graham has made trial runs and test crushings and concentrations on the company's ore. The mill is 70 feet wide, 130 feet long and 73 feet high.—The Detroit mine on Gibson hill is to be reopened by S. M. Perry of Denver and G. C. Smith of Breckenridge.—At Frisco the Mary Verna mine is shipping ore from its upper workings and the large development tunnel is being pushed ahead by three shifts.—The main tunnel of the North American mine is progressing rapidly. The company operating this and the Mary Verna mine, which are under the same management, are considering installing an air compressor midway between the two main tunnels, in order to run these in with machine drills.—At the Jessie mine the leasers are running their 40-stamp mill full capacity.

#### Teller County.

(Special Correspondence).—The Portland G. M. Co. did not appropriate the amount necessary to guarantee the drainage tunnel for the Cripple Creek district at a recent meeting. The Portland Co. has not refused to put up a reasonable amount, but they believe the amount assessed against them is more than they should pay. It is believed that later on, as soon as they can investigate thoroughly the condition of affairs, they will come forward with what they consider a fair proportion to the benefits they will receive from the tunnel if it is completed.

Cripple Creek, May 2.

F. M. Woods, general manager of the United Gold Mines Co., reports that the company will take over the W. P. H. property on Ironclad hill, Cripple Creek, and work and operate the mine on company account.

The Sundown mine of the H. H. H. Co. at Cripple Creek and the Dan McDonald adjoining are to be worked by H. W. Humphrey of Denver. The Sundown shaft is down 400 feet.—The Commonwealth M. & M. Co.'s Star drift, on the east slope of Beacon hill, is 100 feet from the shaft and is following a vein.—Superintendent Donahue, of the Co-operative Co., operating on the Rose Maud mine, Cripple Creek, is shipping regularly. During recent thaws the waters of Anaconda creek flooded the Rose Maud shaft, seeping through the embankment below the collar. It arose above the third level for considerable distance, drowning out the pump and forcing miners to the surface.—L. G. Henry, leasing the Peggy mine on Gold hill, Cripple Creek, has opened up high-grade ore at the 350-foot level.—Hower and associates are operating under lease the main workings of the Dante on Bull hill, Cripple Creek, and will commence sinking the shaft another 100 feet which, when completed, will give them a total depth of 650 feet.—Air drills and compressor, formerly operated on the Gold Hill tunnel, have been moved to the south end of the Gold Bond property, Cripple Creek.—Lessee Paul S. Penn and associates, who recently secured a lease on the Red Spruce mine on Gold hill, Cripple Creek, have started to crosscut from the bottom of the shaft at a depth of 360 feet.—On Battle mountain, Cripple Creek, the Granite G. M. Co. at a depth of 400 feet have opened a new ore body and another one at depth of 1000 feet through the main working shaft.—The Rose Nichol shaft on Battle mountain, Cripple Creek, has reached the 550-foot level, and prospecting drifts have been started.—On the Burns claim of the Acacia Company, the Exposition Mines & Leasing Co. has resumed sinking at a depth of 260 feet. Another lift of 100 feet will be added. To advance work with greater speed a heavier hoisting plant will be put in. The one arranged for is that formerly used in hoisting from the Wrockloff shaft, on another block of the same property.

## IDAHO.

#### Blaine County.

E. W. Packard and J. C. McChrystal of Salt Lake City, Utah, recommend a temporary suspension of operations below the 900-foot level of the Tiptop mine, near Hailey, while the upper levels are developed more thoroughly.—The Wood River Zinc Co. has started work in the Noy Aug group, in Panther gulch, near Hailey.

#### Boise County.

J. Fullard of the Mammoth mine, near Placerville, says the shaft is down 360 feet and will be sunk 400 feet and then a crosscut will be driven to the ledge.—J. H. Emery, president and manager of the Gold Coin M. Co., has men enlarging the Solomo ditch, on More creek, near Idaho City, to furnish water power for an electric plant to be put in to run the hoist and mill at the mine. The mill will be built the coming summer. Work will be resumed in the mine as soon as supplies can be hauled.

#### Latah County.

Superintendent J. W. Sherer of the White Cross mine on Moscow mountain, 8 miles from Moscow, reports a strike of high-grade ore. The 5-stamp mill is running steadily.

#### Shoshone County.

The Black Cloud mill, on Nine Mile creek, near Wallace, has started on ore from the Black Cloud mine.—Men are at work on the Panhandle mine, near Wallace, grading a site for the main working shaft.—The Success M. Co. has been formed by H. F. Samuels, J. L. Bailer, C. F. O. Merriam, J. J. Burch and A. H. Featherstone to work the Granite mine on Nine Mile. Plans are being drawn for a mill of 100 tons' daily capacity to extract the zinc values. The lower tunnel is 1200 feet in length and 418 feet below the old upper workings.—The Silver Star M. Co. of Wallace has let a contract to widen, straighten and timber its lower tunnel, and as soon as this work is accomplished another contract will be let to extend the tunnel 150 feet farther. It is calculated that this extension will bring the tunnel under the blowout and croppings on the surface. W. H. Batting is president and W. J. Bracking secretary.—The Idaho Free Press reports that jiggling operations on Canyon creek, near Wallace, are proving successful. The largest plant now at work is that owned by W. R.

Swicegood, D. L. Hoppins and J. Kelly at the No. 4 dump of the Standard mine. This plant was installed last fall and was in continuous operation until cold weather and a shortage of water compelled it to close down. It resumed operations two weeks ago, with three jigs being worked. —Bannister & Co. at Gom are working two jigs on the north bank of Canyon creek, below the outlet of the Hecla mill. —On the hill above the Hecla mill the Cook boys are working two jigs and four men on one of the old Gem mine dumps. —The jig at Granite has quit. —The two jigs at Frisco are idle, owing to the high water in the creek. —The two-jig plant at Upper Mace, below the O. R. & N. bridge, is temporarily idle. —A one-jig plant is being operated by W. R. Swicegood, G. Ehrenberg and J. Sleeper on one of the Helena & Frisco dumps. —Bannister & Co. have made arrangements to work the bed and banks of Canyon creek from below its junction with the main river from Mullao up to the outlet of the Standard and Mammoth mills.

According to the report of the management, 12,271 tons of ore were extracted from the Hercules mine at Wallace in 1904, giving a gross value of \$928,877, and a net profit of \$430,418. This record is made without a mill. The ore as mined is hauled 2 miles to the railroad and shipped in its crude form to the smelters. The owners have commenced building a 200-ton concentrator. —The Federal M. & S. Co.'s report for 1904 shows the net profits of the company's four mines in the Cœur d'Alenes to have been \$1,169,036. There were 672,669 tons of ore extracted, giving a gross value of \$4,760,181. The actual cost of extraction was \$1,994,434. The cost of transportation and reduction was \$1,525,424, while the cost of betterments was \$70,285, making a total expenditure of \$3,591,145.

#### Washington County.

President D. C. Nevin of the Iron Spring M. Co., at Iron Springs, has returned from the East, where he spent two months purchasing machinery for a 100-ton cyanide plant. —The Gold Coin mill at Black Lake has been temporarily shut down, owing to an accident. A drain tunnel 1000 feet long will be run in the mine to drain the workings.

### MISSOURI.

#### Jasper County.

(Special Correspondence). —Holmes, Capos & Rogers of Joplin have purchased the Old Hickory mill at Chitwood and are having it moved to Badger and Peacock valley. —W. E. Morgan of Joplin has a lease on the Dugan diggings on the Roh Roy land, 1 mile south of Villa Heights. —The Charter Oak M. & M. Co., of which J. E. Putnam of Joplin is manager, has resumed operations on the John Jackson land at Chitwood. —A. Scott and J. McCarthy of Joplin and R. A. Mooneyham of Carthage, owners of a prospect on the Granby land at Smelter hill, are figuring on building a mill. —H. Cavanaugh and others of Carterville have commenced work at the Dividend mine at Midway. —Prospectors are at work on the Mahaska land, adjoining the Empire M. Co.'s land at Joplin. —Gohar, Herron & Co. of Joplin are producing three tons of zinc and two tons of lead weekly from their mine west of Joplin. —Iona, Mich., parties have built a new 100-ton mill north of the Utopian M. Co.'s property under direction of J. A. Peck. —McClure, Jenkins & Goatley of Joplin, on the R. F. Poundstone land east of Oronogo, have their drill hole down 250 feet and have found rich ore. —Chapman & Lennon of Joplin, who recently commenced rebuilding a mill on the Reliance M. Co.'s land at Neck City, have the mill almost completed. —G. E. Moore of Monticello, Ill., and brother, A. L. Moore of Chicago, Ill., who recently secured a lease 6 miles north of Neosho, have opened up ore in the sheet ground at a depth of 120 feet and are now figuring on moving a mill to their land. —G. Brand and others of Neosho, who recently secured a lease on forty acres of the W. G. Wills land, near the old Mosely mines, north of Neosho, are now sinking a shaft.

Joplin, May 1.

#### Stone County.

The Hoho M. Co. have put up a steam hoist and pump on their new shaft near Baxter. —The Dark Horse mine, near Baxter, is working on good ore. Manager W. T. Apple and Superintendent Davidson will put in machinery for a concentrating plant. —At the M. K. & T., near Baxter, Superintendent D. McRuer has his elevator up, the crusher doing good work, the 4-inch pump throwing water nicely, six hand jigs running steadily, and good ore. —Scoles & Horning, who struck a deep run of ore at Galena, have their shaft down 75 feet and are building a new derrick preparatory to putting in a steam hoist. —Repairs are being made on the pumps at the Pittsburg No. 2 shaft at Galena. —J. Keys and others have a lease on the Oronogo mill, on the McCann lease, southwest of Galena, and are running on tailings.

### MONTANA.

#### Fergus County.

It is reported that the stamp mill at the Garnet G. M. Co.'s property near Pony has been started. —The Strawberry mill, near Pony, will probably be increased by ten more stamps, making twenty in all. The ten stamps are dropping on ore from the Clipper mine, on Mineral hill. —Operations will be resumed at the Watseca property, near Rochester, on the tailings of the new mill. —Near Maiden, G. Bellis is developing the Collar gulch property.

#### Granite County.

The iron and copper mine on Franklin hill, near Philpshurg, owned by E. Sifton, C. E. Moore and G. T. Cape, has been leased to W. Frost of Butte, representing a Butte company. The mine is near the Jackknife bend, on the Granite road, and has been opened up by several tunnels. Beside iron, the ore carries values in copper and is valuable for fluxing purposes. It is the intention to ship several carloads of ore per day to the Heinze smelter and the Butte Reduction Works at Butte.

#### Levi and Clarke County.

The Red Bird Co. of Helena is working the Reliance group, in High Ore gulch. High-grade ore has been

found in two places where levels are being run and a winze sunk. The company has men at work on the Red Bird, near Austin, making shipments. The incline will be extended another 100 feet from the 300-foot level, and a four-drill compressor and additional boilers are being put in.

#### Madison County.

It is reported that Superintendent J. H. Pankey has started unwatering the Easton mine, near Virginia City. The Easton mill has been closed for repairs. —The Conrey Placer M. Co. is said to have purchased the power ditch between Waterloo and Parrott, together with the power plant at Parrott. The Conrey Placer Co. operates dredger boats near Ruby, and it is stated that they are to construct a power line to connect the power plant with their dredgers and operate them by electricity.

#### Missoula County.

The tunnel being driven at the Nome mine, near Clinton, to strike the lead of the Bullion, is in 700 feet. H. T. Wilkinson of Missoula is interested.

#### Silver Bow County.

(Special Correspondence). —It is reported that negotiations have been reopened for a settlement of the copper fight in Montana between F. A. Heinze and the Amalgamated Copper Co., and, in connection with it, it is stated that H. H. Rogers will retire from personal management of Amalgamated affairs. —Senator Clark has ordered the construction of a 350-foot stack with dust chambers to recover arsenic and other values from the smelter smoke. —The Montana Coal & Coke Co. has resumed operations, after a suspension of six months, owing to labor troubles. The Montana smelters have in the past consumed all the product of the coal mines of that company and the Amalgamated has an option on a majority of the stock of the corporation, but has not yet indicated its intention to take up the option. The matter has been referred to B. B. Thayer, general manager, by H. H. Rogers and he has not yet acted. —The properties of the Speculator M. Co. will be formally transferred to the North Butte M. Co. —The Pittsburg & Montana Co. will be able to resume development work on its veins next week, when the accumulated water in the workings will have been pumped out, but there is no prospect of an early beginning of actual mining operations. —The Reins Co. has suspended work in the Combination mine on account of too much water.

Butte, May 1.

### NEVADA.

#### Humboldt County.

J. A. Nelson of Humboldt has sold his copper mine at Jackson creek to Malley & Darling of San Francisco, Cal., for \$60,000, the new company being known as the Humboldt C. Co. and intending to work the property on a large scale.

At Kennedy, J. R. Benton and C. E. Kennedy are working the Fourth of July and Hazel Bell. —Calhoun & Chamberlain are working the Hidden Treasure mine and running the 2-stamp mill at Kennedy. —It is reported that the Federal Mines Co., G. W. Dyke superintendent, will build a dredger to work the Spring Valley placers near Kennedy, hauling the machinery from Lovelock.

#### Lander County.

E. W. Carman has men working his claims in Red canyon, near Battle Mountain. As soon as the snow is gone work will begin on the lower levels.

#### Lincoln County.

The Keystone mine in the Yellow Pine district, 7 miles east of Sandy, which was recently sold to an English syndicate for \$337,500, is working twenty-five men. It is down 1100 feet on a ledge of talc. They have a 20-ton mill and 30-ton cyanide plant. —T. A. Johnson of the Con. Johnnie G. M. Co., 50 miles southeast of Bullfrog, says that 6000 feet of development work have been done on the Johnnie, including a shaft 500 feet deep. C. Schader is manager. In connection with the mine the company have organized the town of Johnnie, which has made application for a postoffice and expects to have a railroad connection soon. On completion of the Salt Lake Railroad a mail route will be extended from Good Springs siding to Good Springs, Sandy, Manse, Johnnie and north to Beatty.

H. T. Johnson of Los Vegas has taken an option on the Lucy Hawthorne and the Bug mines at Eldorado for \$15,000. —G. H. Atkins of Milford reports a strike in the Red Cloud mine at Good Springs. —The Pioche-Nevada Con. Co. at Pioche has just struck good ore.

Manager C. E. L. Gresh of the Black Hawk M. Co., at El Dorado canyon, has put a small hoist on the Buster claim and will sink the main shaft 50 feet to the 115-foot level and connect with shaft No. 1, down 165 feet, and shaft No. 3, down 85 feet. —G. M. Rose is building a 100-ton plant at Searchlight to work the Southern Nevada tailings.

#### Nye County.

Superintendent J. Simpson says that the main shaft of the Bullfrog M. Co. is down 70 feet, working in good ore. Two drifts, 20 feet each, have been run off the shaft into the ledge. The main tunnel, 220 feet deep, has cut four bodies of talc, revealing deposits of milling ore. Another crosscut 1500 feet from the shaft has uncovered a 6-foot ledge. A mill will be put in operation before October 1.

### NEW MEXICO.

#### Grant County.

J. Hartzog and M. T. Everhart report a rich copper strike in the Big Hatchet mountains.

#### Rio Arriba County.

M. Gill has six men at work upon the placers at Hope-well and intends to increase the force to twenty. —L. K. Kramer will work the Red Jacket and Dixie mines of the Queen M. & M. Co.

### OREGON.

#### Baker County.

Superintendent B. Rusk of the Platts group, Rock Creek district, reports that he has cut a rich body of ore in the main drift.

#### Grant County.

Operations are to be resumed at the Uncle Sam group, near Granite, under the management of S. S. Start of Sumpter. —The Scandia tunnel will be continued again. This tunnel is run through mineral ledges in the Alamo district and is in over 3000 feet. Work was suspended Jan. 1—the first shut-down for three years. W. Wade of Sumpter is manager.

Copper is being opened in a new district 15 miles from Izee. —It is reported that Manager W. J. Hughes of the Equity mine, near Prairie City, will put in a larger mill. —Superintendent J. Waddell of the Prairie Diggings, near Prairie City, is opening that property for heavy work and will sink the shaft 400 feet. It is now 200 feet deep, with two levels.

#### Josephine County.

The longest electric power wire for Oregon is that to be strung from the power plant of the Condor Water & Power Co. at Gold Ray to the Greenback and Martha mines on Grave creek. The distance from Gold Ray to Greenback is 45 miles. It is reported that arrangements have been made between the Condor Co. and the Greenback and Martha mining companies to supply all necessary power for the operation of these mines by electricity. —The placer season has been unusually short, owing to the light rain and snowfall, and already the streams are as low as they usually are in midsummer. The season has been a profitable one, and the amount of dust taken out will not fall far short of the average. The Galice Con. has done and is doing much preparatory work, and by the time the water comes again will be in shape for a big run. —At Silver creek the season has been good. The Metz & Leigh tunnel is in 900 feet, and at the 100-foot mark an upraise will be put through to the surface. This company has a trail from Galice creek 16 miles, and is preparing to build a wagon road from that point to its mines.

S. Chase, owning the Oro Fino, in the Joe Creek district, near Grants Pass, has been arranging to complete installation of his milling and cyanide plant this spring and commence treating ore. The plant consists of a Sturtevant breaker and one set of rolls combined, and leaching vats.

#### Lane County.

The Uncle Sam mining property, in the Blue River district, has been sold at sheriff's sale to J. W. Shumate of Wativille for \$5955.50.

### SOUTH DAKOTA.

#### Pennington County.

The Gopher G. M. Co. is putting in a compressor plant, drills and 5-stamp mill at the Gopher property, 3 miles north of Hill City. The Gopher shaft is down 175 feet. The company is preparing to build a power plant for its mill in Gopher gulch.

### UTAH.

#### Joab County.

The Mammoth mine at Eureka has been temporarily closed down by Superintendent S. McIntyre, laying off 135 men.

The shipments for April, ending the 27th, from Tintic mines were: Centennial-Eureka 351 carloads, Eagle & Blue Bell 26, Mammoth 41, Godiva 1, Yankee Con. 10, May Day 22, Uncle Sam Con. 13, Star Con. 1, South Swansea 4, Bullion-Beck 31, Gemini 42, La Clede 1, Carisa 5, Grand Central 19, Ajax 9, Bales, lease, 1, Osborn, lease, 1, Paxman, lease, 1, Victor 3, Godiva 2, Brooklyn 1, Swansea 2. Total, 587 carloads.

#### Plute County.

The I X L tunnel at Marysville is in 1200 feet and is to be continued. J. S. Snow of Manti is president.

#### Salt Lake County.

A. E. Snow, secretary and treasurer of the Columbus Con. M. Co. at Alta, reports that during March there were 454 tons of concentrates produced, of a value of \$28.24 per ton, or a total of \$12,820.02. The expenses were \$7000. The mine delivered to the mill 1768 tons of crude ore. The recovery from this ore amounted to \$8.74 per ton, distributed as follows: Silver, 8.59 ounces; lead, 2.85%; copper, 1.38%. The loss in tailings was \$2.70, distributed as follows: Silver, 3.32 ounces; lead, .12%; copper, .41%. The ore was concentrated in the ratio of 3½ tons of crude ore into 1 ton of concentrates. The average per cent saved was 99½. The principal development work now being done consists of the sinking of two shafts from the tunnel level. One is near the big lead stope. The other is a new shaft that is being sunk to operate the Howland ore body. The former shaft is down 100 feet. Drifting has now begun from the bottom, both east and west. The water in this shaft near the big lead stope makes it difficult and expensive to sink. The shaft which is being sunk at the Howland is about 100 feet from an older shaft that was standing full of water. When this water was pumped out the shaft was found to be caved, and it was considered advisable to sink another rather than clean the old one. The new one is double compartment and is now down 50 feet, and will be sunk to the 100-foot mark before drifting.

It is reported that the Utah Copper Co.'s mine is supplying the mill at Bingham Canyon with 900 tons daily. The main tunnel and a number of the laterals have been wired and the 5-ton electric locomotive has started hauling cars. It is expected to connect the 3rd east crosscut with the Quinn tunnel, giving a complete circuit. —The remodeled Kempton mill at Bingham is expected to start up soon. —The Utah Apex Co. is putting in a compressor near the mouth of the Corman tunnel. Superintendent McCree is shipping ore from the Parnell and Annie, near Bingham. —Superintendent G. Hannahs of the Starless mine, at Bingham, has started work on the Amanda tunnel, through which the property is to be developed under the Wall option. The tunnel has been cleaned out and an electric hoist put in. —The copper ore body recently opened up in the Keystone tunnel of the Fortuna Co., at Bingham, holds out good. Superintendent Start is sinking a winze from the tunnel level. —H. M. Adkinson, manager of the New England G. & C. Co. at Bingham, reports that he has resumed

milling operations. The enlargement of the plant will be commenced soon.—The Mystic Shrine property at Bingham, one of the promotions of E. W. Young of Denver, Colo., is reported to have passed into the possession of F. G. Shafer of Denver.

#### Sevier County.

It is reported that S. W. Tulloch, president of the Sevier Con. G. M. Co. on Gold mountain, near Richfield, has recommended that the mill capacity be doubled.

#### Summit County.

The tunnel on the Martin G. & S. M. Co.'s property in Thayne canyon is in 250 feet. A. F. Martin is in charge.—A. H. Elftman, consulting mining engineer of the Mount Masonic M. Co., at Park City, is at the mine from the Black Hills of South Dakota to inspect the recent development work at the property. The tunnel is now in 900 feet.

#### Tooele County.

Superintendent H. D. Trenam of the Stockton G. M. & M. Co. of Stockton reports that the mill is running steadily. The main shaft is being sunk deeper and will be continued to the 850-foot point, where a level will be established. The present depth of the shaft is 800 feet.

#### Utah County.

Manager H. J. Kruse of the Bog mine, in American Fork canyon, states that the water seam has been tunneled through and the face of the tunnel is dry.—The owners of the Steele property, in the head of American Fork canyon, are preparing to continue development.—J. H. Wooton of American Fork will start work on the Silver Glance.—The Gold Gem, known as the Cedar Stump discovery, near the mouth of American Fork canyon, will commence work on the 150-foot tunnel which will be run to tap the vein 100 feet below its present workings.—The Silver Flat M. Co. of American Fork intend to resume work on the Copper King.

F. C. Tyng, operating the Wyoming mine in American Fork canyon, says that conditions will not permit of any ore being shipped inside of six weeks. Men are working at the mine.—The Buckley mine, operated by Woodward Bros. in Rock canyon, west of American Fork, has shipped its first car of ore.—The Signet mine in American Fork canyon is running a 250-foot tunnel, following a well-defined vein.—G. Summerville, foreman of the Blue Rock mine in American Fork canyon, reports that the mine is being worked steadily.

### WASHINGTON.

#### Ferry County.

A new ore body is reported in the Morning Glory mine under lease to J. S. Berdiere of Republic.—At the Ben Hur mine the two drills are operated day and night. The ore which is being exposed is said to be of very good grade.

T. M. Hammond is making a preliminary survey for a railroad spur from Lambert creek to the summit of Belcher mountain. The mountain side is very steep and good for a 3% grade. Another route will be surveyed later on from Torboy, up the north fork of the San Poil river. These surveys are said to be for the purpose of ascertaining the cheapest mode of conveyance of ore from the Belcher mountain mines to the Washington & Great Northern and the Spokane & British Columbia River railroads.

#### Pierce County.

It is reported that the Tacoma Smelting Co. has completed its 300-foot reinforced concrete chimney at the smelter. It has an inside diameter of 18 feet and is designed to save the values from the fumes, to abate the smoke nuisance and to increase the draught.

#### Snohomish County.

Work is to be resumed at the "45" mine at Sultan.—Work on the Hecla, on Salmon creek, has been started by A. M. Watt.—Work has been started on the Bonanza Queen mine, near Silverton, by Superintendent S. A. Warner of Seattle. A new compressor is to be put in and driven by water power to be developed during the present season.—Work is being pushed on the property of the Buckeye C. Co.

### WYOMING.

#### Carbon County.

J. A. Phillips has sold his interests in the Phillips coal mines, 15 miles down the river from Saratoga, and the McCoid mine, 22 miles northwest of Saratoga, to A. J. Chidster of Grand Encampment and W. C. Sammons, agent for the Union Pacific at Walcott. The new owners will develop the coal mines at once, and place their product on the local market.

### FOREIGN.

#### AFRICA.

##### The Soudan.

W. Broadbridge, in the Mining Journal, discusses the possibilities of the Soudan as a gold field. The mines are within eight days' camel ride of the Suakim. Running north-south there is a chain of mountains 5000 to 6000 feet high. On the east side these mountains have smaller ranges of hills which terminate in undulating sandy plains extending to the Red sea. On the west are numerous inside ranges of hills stretching for 50 to 60 miles, where they join another range of mountains parallel to the main coastal range. These inside ranges are intersected in all directions by valleys and gorges, locally termed waddys, some descending steeply from the hills, others extending in flats over considerable distances. These waddys are the natural agricultural and pasture lands of the country; they support large herds of camels, goats and sheep. At one time this portion of the African continent evidently formed part of one vast tableland, the sedimentary rocks comprising this plateau having been depressed and the coastal ranges of granitic rocks uplifted. Accompanying these dislocations were numerous overflows of diabasic and dioritic rocks. The deformation of these rocks has resulted in considerable metamorphism, the resulting rocks being schists, gneiss

and conglomerates. Later posterior eruptions of trap-  
pean rocks, with faulting above zones of weakness dur-  
ing more recent geological ages, have produced the  
deposition of quartz reefs, more or less auriferous, ex-  
tending over a large area. The auriferous deposits are  
confined to the later formations and occur as fissures  
traversing both sedimentary and intrusive rocks and as  
impregnation deposits following the laminations of the  
enclosing rocks. The natives of the district are the  
Bischarin and Hadendowa Arabs. In disposition, by no  
means truculent, they are indolent and easy to get on  
with. They appear to like the idea of their country  
being opened up. While being by no means what we  
call fertile, still in districts, after a sufficiency of rain, the  
country is capable of a high state of cultivation. The  
methods of mining adopted by the ancient workers ap-  
pear to have been of two kinds, the first consisting of  
working the reefs from the outcrops downwards, follow-  
ing the reefs presumably to water level, or until it be-  
came unpayable; the second, in sinking a series of shafts  
in the line of reef and opening up stopes. They do not  
appear to have carried any drives or levels, the quartz  
mined being passed from man to man until it finally  
reached the surface. At the surface it was ground by  
hand between large stones, these grinding stones consist-  
ing of a lower stone which formed the mortar, the upper  
stone fitting in this and being turned by hand by means  
of an upright piece of iron or wood fitted into the stone.  
The stones forming the mortar are between 18 inches  
and 24 inches in diameter, shaped in the form of a circular  
basin. The quartz to be ground was fed into the  
mortar through a central hole in the upper or grinding  
stone. Both these stones consist of a very hard  
diorite and were evidently imported, no similar  
rock being found in the vicinity of the mines worked.  
The stopes that have been opened up in most instances  
were very narrow. All ore mined was worked out by  
means of hammers and chisels. On the whole, one could  
not be but favorably impressed with the possibilities of  
opening up a mining industry in the Soudan. The  
ruins of old mining camps, grinding stones and large  
dumps prove that in the past mining was conducted on  
a large scale, also that large quantities of the precious  
metal have been obtained. The local Arabs are not to  
be relied upon as a possible source of labor. The Fella-  
heen of Lower Egypt are a hard working, civil and  
indigenous to the country; there is here a large supply  
of labor ready to hand. The price for drill boys is £3  
per month; the price for laborers is £2 per month. In  
both cases they have to be fed, entailing a cost of 15s  
per man, bringing the cost, say, to £3 and £4 per month  
respectively. In addition there is the Italian miner,  
who can be imported into the country at £6 per month.  
He requires his food and passage, thus bringing his  
wages to £12 a month on a yearly contract. These men  
are the best class of miners—one accustomed to modern  
methods—the majority being excellent machine men.  
With mines lying 100 miles from the coast or the Nile,  
roads can be constructed with but very little expendi-  
ture. The waddy beds, with the larger sized boulders  
removed, would very soon make good roads. The local  
camels are obtainable in almost any quantity; they  
carry loads up to 300 pounds comfortably, traveling 15  
miles a day, the rates being small. In southern Egypt  
one sees small carts, carrying 1500 pounds dead weight,  
drawn by camels; these can be utilized in the Soudan.  
Camels to buy for transport purposes cost from £5 to  
£7 apiece. The Berber Suakim railway will be finished  
shortly; this will help considerably any mine opened up  
in its vicinity. Rates for transport should never exceed  
£5 per ton, and will probably cost considerably less.  
Timber is entirely absent from the country (with the  
exception of thorn trees), but can be imported direct  
from Europe at low rates. As regards timber for under-  
ground work, the want of local supplies should not pre-  
vent economic mining. Timber being absent, one has  
to fall back on coal or petroleum for power. Petroleum  
will cost, in most districts, up to £8 a ton delivered, as  
against coal at £6 a ton. The lack of water will be found  
the greatest drawback as regards economic and constant  
working. For reduction purposes one would have to  
rely either on the rainfall or wells; the water would, of  
course, be returned again and again, and if augmented  
with any mine water, should prove sufficient. For  
domestic purposes it is safe to assume a sufficient supply,  
as in most parts of the Soudan, water is found at com-  
paratively shallow depths. Provided water is obtain-  
able in sufficient quantities, working costs, including  
development, should not exceed 30s a ton, for labor is  
plentiful and not high priced; transport is cheap; sup-  
plies are obtainable at about 10% above European rates.  
To offset these factors are narrow reefs and high cost of  
fuel—but 30s a ton may be considered an ample margin.

### CANADA.

#### BRITISH COLUMBIA.

##### Boundary District.

Boundary ore shipments run over 300,000 tons for this  
year, the output for week ending April 29 being: Granby  
mines to Granby smelter, 12,390 tons; Mother Lode to  
British Columbia Copper Co. smelter, 4064 tons; Brook-  
lyn to M. & S. smelter, 2555 tons; Rawhide to M. & B.  
smelter, 763 tons; Mountain Rose to British Columbia  
Copper Co. smelter, 217 tons; Dominion Copper Co.'s  
Brooklyn and Stewindur dumps, 460 tons, to Trail  
smelter; Oro Denoro to Granby smelter, 100 tons; Provi-  
dence to Trail smelter, 20 tons; Last Chance to M. & B.  
smelter, 46 tons; E. P. U. to Trail smelter, 20 tons; total  
for week, 20,635 tons; total for year, 305,488 tons. The  
three district smelters treated ore as follows: Granby  
smelter, 12,500 tons; British Columbia smelter, 4126  
tons; Montreal & Boston smelter, 3342 tons; total for  
week, 19,968 tons; total for year to date, 310,775 tons.

##### East Kootenay.

The agreement between the C. N. P. Coal Co. and its  
employees, which has been in force since April 1, 1903,  
will expire on May 31, on notice from the miners' union.  
A new agreement has practically been arrived at and all  
fears of a strike are dissolved. Various conferences have  
been held between Manager Lindsey and Superintendent  
Drinnan for the company, and a committee of the

miners' union, and a settlement of a schedule and other  
particulars has been reached to the satisfaction of both  
parties. The committee of the miners consisted of F. H.  
Sherman, president of the district union of the U. M. W.  
of A.; P. Patterson, vice-president, and Biggs, Severn  
and Lawrenson, representing respectively the local unions  
at Fernie, Carbonado and Michel. This committee was  
assisted by W. E. Jones of Dietz, Wyo., who is a mem-  
ber of the international board of the U. M. W. of A.  
The agreement is to remain in force until March 31,  
1907, the expiry date of the U. M. W. of A. agreement  
in Alberta. The new schedule is similar to the old one,  
with a few minor changes. The C. N. P. Coal Co. is  
about to put in a compressed air locomotive system in  
No. 8 mine, Michel. The compressor, which will be in  
the power house, will have a capacity for charging  
the locomotives with 800 pounds pressure to the square  
inch. The air will be conveyed to the mine in pipes and  
along the entry will be charging stations where the two  
locomotives may be charged. These locomotives will  
have a daily capacity of 1200 tons. They will be suffi-  
ciently powerful to haul a train of forty loaded cars up a  
31% grade. At Michel there are six producing mines in  
active operation and two others being opened up. These  
are opened up by the pillar and stall method worked in  
panels. Mine haulage has been by rope. Ventilation is  
by fans worked as exhausters.

#### Roseland District.

The tonnage of ore shipped from and crushed at the  
Roseland mines for the week ending April 29 and for the  
year to date was as follows:

Mine.	Week.	Year.
Le Roi	2,100	44,805
Center Star	2,010	30,988
War Eagle	1,280	21,450
Le Roi 2	130	3,623
Le Roi 2 (milled)	1,600	1,600
White Bear	25	1,100
White Bear (milled)	300	3,000
Jumbo	400	2,925
Spitzee	90	3,614
Velvet-Portland	1,977	1,977
Totals	6,335	115,087

### JAPAN.

The Far Eastern Review, in describing the coal mines  
of the Kaijima M. Co. on the island of Kyushu in the  
prefectures of Fukuoka and Saga, says that the collieries  
at Ohnoura, Ohtsuji and Yunokibaru produce 2061  
tons daily. The Ohnoura coal is won by pillar and  
room system with hand work. Timbering consists  
mostly of pine logs, but near the pit brick supports are  
in use. For drainage purposes sixty-three special pumps  
are installed at the pits, and altogether 125 cubic feet of  
water per minute is pumped out of the mines. Ventila-  
tion is effected naturally except in the case of the Kirino  
mine, where a Champion ventilator, capable of discharg-  
ing 75,000 cubic feet of air per minute, is worked by  
steam. The mines are lighted by Davey and Clanny  
safety lamps. At the Sugamuta mine, electric light is  
used on the surface. There are 6800 mine workers em-  
ployed at the mine.—Trunk railway is constructed on  
the chief mine roads. To hoist cars running on rails,  
six winding engines are worked by steam. Surface  
transport varies according to the mines. In the case of  
the Sugamuta mine, the coal from the different pits is  
conveyed to the screening house at the mouth of the  
shaft by endless rope tramway. After screening is  
effected, the coal is transported to the company's coal  
sheds at Katsuno, and there it is loaded in railway cars  
and sent to Wakamatsu (18 miles) or Moji (20 miles). In  
the case of Ohnoura mine, the coal is transported to the  
screening plant at Kirino, and there loaded in railway  
cars to be sent to Wakamatsu or Moji. In the case of  
Kirino, the coal is directly put in railway cars after  
screening and conveyed to Wakamatsu and Moji, 20  
and 31 miles respectively. In the case of Mannoura, the  
coal, after it is lifted out of the mines, is drawn by horses  
on rails as far as the Inunaki river, 7200 feet, thence to  
Kirino (2400 feet) by endless rope tramway. At Kirino  
the coal is transferred to railway cars and sent to Waka-  
matsu or Moji. The Ohtsuji colliery comprises the  
Ohtsuji Nos. 1 and 2, Shiraiwa Nos. 1, 2 and 3 in Onaga  
district, Chikuzen province. The product is carried to  
the canal at Wakamatsu. The colliery is 1 mile south-  
west of the Azamibaru station on the Karatsu branch of  
the Kyushu railway. The mining concession covers an  
area of 1979 acres. The method of mining is that of the  
longwall and pillar and room systems combined. There  
are eight special pumps at work for drainage purposes.  
The length of the drift is 3090 feet. The workmen em-  
ployed in and out of the mine workings exceed 1000.

### MEXICO.

Estimates shows that the new decrees in reference to  
the mining industry of Mexico, which were recently  
promulgated by President Diaz as a result of the plans  
for monetary reform, will save the mine owners of  
Mexico about \$4,000,000 annually. Taxes on the mining  
industry last year provided the Government a revenue  
of \$9,500,000, and as a result of the tax reductions just  
granted the industry will pay no more than \$5,500,000.  
The demands made on the Government by the mine  
owners contemplated a saving of \$5,000,000. It is stated  
that following the establishment in the City of Mexico of  
a permanent commission to represent the mine owners  
of Mexico, a demand will be made on the Government  
for a law providing for the permanent ownership of min-  
ing property. The Government will be asked to issue  
patent rights to mine owners who have paid taxes  
regularly on mining claims for a stipulated period of  
time. At the present time any mining claim is in danger  
of forfeiture through non-payment of taxes, regardless  
of the length of time covered by tax payments. Another  
demand to be made by the mine owners has to do with  
permanent landmarks in the measurement of mining  
claims. At the present time duplicate denunciations  
are of common occurrence.

The National Dynamite Co., which recently had a con-  
siderable portion of its factory destroyed by an explo-  
sion, is importing dynamite from the United States so  
as to make good its contract to supply the market pend-  
ing the repairing of the factory. Work of clearing away

the debris at the factory at La Tinaja, Durango, has commenced and it is claimed that the destroyed portions can be replaced in two months. The annual consumption of dynamite in Mexico is given as 150,000 cases.

#### Chihuahua.

The 15-stamp pan amalgamation mill of the Dolores M. Co. at Minaca has been started. The cyanide plant is not yet completed. J. G. Hardy is acting manager.—J. F. Johnston of Parral is developing the Garniquona, east of El Vallo.

Juan A. Creel, manager of the Banco Minero, has given to C. E. Nord of Chicago an option on the Rio Tinto copper mine at Terrazas. The option includes the smelter on the property.—The annual report submitted by the Batopilas M. Co. at Batopilas for 1904 states that the mill ran 319 days, crushing 27,958 tons of third class ore, which produced 204,697 ounces of concentrates, valued at \$1 per ounce. The bullion product was 516 bars, yielding \$623,542. The average value of the ore was \$21.80 per ton. The ore tonnage was increased by 3024 tons.—The 40-stamp mill of the Pittsburgh-San Jose Railroad & Reduction Co. at San Jose del Sitio has been started up, with N. Rich in charge.

B. Gilpin of Los Angeles, Cal., and H. La Montayne of Hillside, Ariz., have taken over the Prieta mine at Parral and propose to sink the shaft 200 feet deeper.

The Constanza M. Co. at Sierra Mojada is working two mines and have several properties leased to other companies. They have 200 men and are producing 4000 tons. W. Hagemann is manager.—The Cia. Metalurgica Mexicana, the R. S. Towne's properties, under the management of G. H. Carnehan, is working the Veta Rica mine, near Sierra Mojada, producing 1500 tons per month.

#### Durango.

The Lustre M. Co. of Inde is ready to blow in its new 150-ton smelter, this making its third.—W. S. Morse, general manager of the southwestern department of the American S. & R. Co., is authority for the statement that work has been started on the company's new smelter at Velardena. This plant will have an ultimate capacity of 2000 tons daily.

#### Guanajuato.

The La Luz M. & T. Co., which proposes to drain and operate a number of old mines in La Luz camp, has purchased the Bolanitas mine in that camp from Jesus Andrade. Dwight Furness of Guanajuato and G. W. Jennings of the City of Mexico are interested.

#### Jalisco.

Arrangements have been made by the Mazeppa Con. G. M. Co. to take over the Aguila mine in the Hostipaquillo district. The mine is owned by W. T. Thornton.—On the Contla hacienda, municipality of Tamazula, H. Sablayroless of Zapotlan has discovered a new silver vein.

The Zapopan G. M. Co. proposes to run a crosscut tunnel into the Zapopan, in the Yesca district, to cut the vein below the old workings.—The Aztec C. S. Co. of Philadelphia, Pa., is preparing to put up reduction works on its property north of Huacabinango. Timber is being cut on the land and the roads to the mine put in shape, preparatory to bringing in the machinery. The company, of which G. J. Graham is general manager and J. P. Johnson superintendent, owns the mines Perla, Concha and Mascota. The ores are copper, gold and silver and the development consists of shafts and crosscut tunnels.—Good ore is being taken from the San Juan shaft of the Cinco Minas property in the Hostipaquillo district. The reduction works are at the Santo Tomas hacienda, 25 miles distant, and the old process of ore treatment, amalgamation by arrastras and patio, with water for power, is still followed.—H. H. Sawyer of Philadelphia, Pa., has purchased the mines of the Bautista M. Co., in the Bautista camp, 70 miles south of Ameca, and the company will erect a reduction works to treat the ore at the mines.

W. M. Mathews, of Etzatlan, has sold to R. C. P. Smith and associates of Los Angeles, Cal., the Refugio mine, between Etzatlan and Ahualulco. Work has been commenced.—A. R. Mignon, of Fort Worth, Texas, has been at Etzatlan arranging to begin work on the Bonanza mine, 1 mile south of Etzatlan.—The cyaniding plant at the Atrevida mine in the Ameca district, which is owned by Glanville Hart and associate, is now in operation. The capacity of the mill and amalgamating plant at the Atrevida property has been recently increased, and the tailings will now be treated by the cyanide process.—At Parnaso, the San Rafael M. Co., in which W. H. Leonard is interested, has converted the old "hacienda de beneficio" from patio amalgamation to concentration with subsequent cyaniding, and is reported to be getting excellent results.

#### Oaxaca.

The Old Mexico M. Co., F. H. Wilson president, has put in a milling plant on its property, 35 miles from Oaxaca.

#### Sinaloa.

An American company, with a stated capital of \$500,000 gold, has been formed to take over the Yauco mines near Rosario. M. F. Campbell promoted the company, which will be known as the Lomas de Oro M. Co.

### NEW ZEALAND.

It is understood that tests at Charters Towers of crushing and concentrating ore as against crushing, concentrating and grinding, have resulted in favor of the latter, the grinding invariably giving satisfactory returns. Of two lots of ore from the Ruby mine, 108 tons crushed and concentrated at the Lady Florence mill realized £1056 10s, while 108 tons crushed, concentrated and ground at the Bonnie Dundee mill yielded £1109 18s, the grinding thus showing to advantage £53 7s 9d, or 10s per ton. It is now anticipated that grinding will be more largely resorted to.

### Dividends.

The Bunker Hill & Sullivan Mining & Concentrating Co. has declared dividend No. 91 of \$150,000, payable on May 4th. This makes a total paid since January 1st, 1905, of \$525,000, and a total to date of \$2,796,000.

## Personal.

C. M. FUELLER of Denver, Colo., is in Birmingham, Alabama.

F. KAHN of Inde, Durango, Mexico, has been in New York City.

A. C. WERDEN has charge Reliance M. & M. Co. near Prescott, Ariz.

J. W. MALCOMSON of El Paso, Texas, has been at Durango, Mexico.

A. A. TAUBENECK is superintendent Tin Pan mine, near Gold Hill, Or.

F. J. FROST is superintendent of mining property near Buena Vista, Colo.

F. W. BRADLEY, E. M., has returned to San Francisco, Cal., from the East.

J. J. DEMING has been appointed superintendent Gold Eagle mine, near Neil, Idaho.

J. B. FARISH of Denver, Colo., has left San Francisco for a two months' trip to the Orient.

G. F. OBER has returned to Denver, Colo., from a trip through Tonopah and Goldfield, Nev.

C. B. EATON has charge of cyanide plant of Supply M. Co. at Dale, San Bernardino county, Cal.

C. D. AVERY has been appointed surveyor for the Gemini & Godiva M. Co. at Eureka, Utah.

C. H. FULTON has been appointed president South Dakota School of Mines at Rapid City, S. D.

F. LONGMAID has been appointed manager Vacas-San Marcos M. & M. Co. at Vacas, Durango, Mexico.

C. E. GROVE is at the Crystal Con. mine at Bohemia, Or., to determine how the ores should be treated.

W. J. KEOUGH of Granite, Or., has been appointed superintendent Minerva M. Co. of Atlanta, Idaho.

W. H. YOUNG, superintendent King Solomon mine, near Cecilville, Siskiyou county, Cal., is at the mine.

N. C. BONNEVIE of Denver, Colo., has returned from mine examinations in Washington and British Columbia.

P. C. MCCARTHY, manager Hidden Treasure mine, Lake City, Colo., has returned there from Denver, Colo.

I. W. VON LEER has been appointed general manager El Carmen Copper Co. at El Carmen, Durango, Mexico.

J. C. BARROWS of Centerville, Iowa, has been appointed manager Mountain Monarch M. Co. of Gilpin, Colo.

C. E. KROH of Kansas City, Mo., has charge of putting in a new mill at the Mayflower mine, Warren, Idaho.

W. DARLINGTON has been appointed superintendent Bagdad-Chase mines, near Ludlow, San Bernardino county, Cal.

H. W. EDMONDSON is superintendent Dolores mine at Minaca, Chihuahua, Mexico. M. P. Lefave is mill superintendent.

F. W. PAGE, general manager United Mexican M. & M. Co., has returned to Mascota, Jalisco, Mexico, from the United States.

F. W. HOAR has been appointed to succeed J. H. Knowles as superintendent and general manager Chiricahua D. Co. at Paradise, Arizona.

T. D. MURPHY of El Oro M. & R. Co. has been appointed assistant manager Guanajuato Reduction & Mines Co. at Guanajuato, Guanajuato, Mexico.

J. P. WEYANT, secretary of the Weyant M. Co., and C. H. Nazro, superintendent of the company, are examining and sampling mines near Weiser, Idaho.

R. C. TURNER of San Francisco, Cal., is acting general manager Dolores M. Co. at Minaca, Chihuahua, Mexico, during the illness of Manager J. S. Hardy in Chicago, Ill.

P. H. MOSMON has been appointed superintendent of the smelter at East Helena, Montana, succeeding W. W. Norton, who is now superintendent Murray smelter, Salt Lake City, Utah.

A. H. LAWRENCE, who has been managing the prospecting operations Los Tajos D. Co. at Morelos, Chihuahua, Mexico, has returned to the United States and expects to go to England.

## Books Received.

"Project for the Panama Canal," by L. W. Bates, gives a good idea of conditions at the isthmus and proposes methods of working that seem to possess considerable merit.

"Mining Operations in the Province of Quebec for 1904," by J. Obalski, is devoted largely to a description of the mineral resources of the Lake Chibogomo region, as discovered on a prospecting trip by the author.

To most engineers the training received in drawing is useful chiefly in the quick interpretation of what another seeks to explain by drawing, and anything that tends to render such representations more intelligible will be appreciated. In "Descriptive Geometry," by J. A. Moyer, the author has given an excellent text book on the principles of orthographic projection. The treatment is

thorough and logical and the explanations are particularly good because of their conciseness. The problems explained are more practical than are usually given in a book of this kind. It forms a valuable addition to the working library of an engineer. It is published by John Wiley & Sons, 43 East 19th street, New York City, for \$2, and will be sent postpaid by the MINING AND SCIENTIFIC PRESS upon receipt of price.

## Trade Treatises.

A booklet for those thinking about pumps from the Goulds Manufacturing Co., Seneca Falls, N. Y., describes triplex power pumps.

"Engineers' Chums," from the Mound Tool & Scraper Co., describes scraping tools, cold chisels, files and packing tools for use in the engine room.

The Urie-Snyder Dredge Co. of Kansas City and 34 South Clark St., Chicago, Ill., issue an interesting catalogue describing their placer dredgers and parts.

Bulletin 51 of the Crocker-Wheeler Co., Ampere, N. J., describes their form F machines, either motors or generators, giving outputs from 3 H. P. to 93 H. P.

The operation and construction of box car loaders is attractively set forth in a recent booklet of the Christy Box Car Loader Co., 811 Equitable Bldg., Des Moines, Iowa.

The eighth edition of the illustrated catalogue and price list of Wm. Powell Co., 2525-2531 Spring Grove avenue, Cincinnati, O., portrays valves, oilers, injectors and gauges.

Fan motors, both direct and alternating currents, are illustrated in Folders 4044 and 4045 of the Westinghouse Electric & Manufacturing Co. of Pittsburgh, Pa. The subject is attractively presented.

The Hardsocg Wonder Drill Co. of Ottumwa, Iowa, in their Bulletin A announce the Big Wonder air hammer rock drill as a 60-pound machine, to be mounted for raising, stopping and drifting in hard, dry ground.

The National Electric Co., Old Colony building, Chicago, Ill., issue an attractive brochure of handsome half-tone illustrations of their electrical apparatus and a few installations in "Plants and Types," a good illustration of printers' fine art.

The Columbia Engineering Works of Portland, Oregon, issues an attractive description of the Phillips Hydraulic Ram, which is so designed that no heavy shocks have to be withstood. Considerable valuable information on hydraulic matters has been incorporated in the booklet, which will interest all engaged in hydraulic mining and irrigation.

## Commercial Paragraphs.

C. O. BARTLETT & SNOW Co. of Cleveland, Ohio, state that they have got part of their buildings under cover and are operating most of their machines, so there will be no delay in getting out orders and filling new ones.

At the annual meeting of the stockholders of the Joseph Dixon Crucible Co. the old board, consisting of E. F. C. Young, J. A. Walker, E. L. Young, W. Murray, G. T. Smith, J. D. Bedle and G. E. Long, was unanimously re-elected. The board of directors re-elected the former officers, namely: E. F. C. Young president, J. A. Walker vice-president and treasurer, G. E. Long secretary. J. D. Bedle was also re-elected as counsel. Of the total number—7345 shares—there were represented 7145 shares.

THE Colorado Iron Works Co. of Denver, Colo., report the following orders and shipments: Copper smelting furnace and equipments for the Cooke City Smelters Co. in Montana; smelting equipments, consisting of one carload of jackets, etc., for the Selby Smelting & Load Co. in California; six carloads of machinery for the Compagnie Francaise de Mines du Laurium smelting plant, near Laurium, Greece, Europe; three carloads of concentrating machinery for the Poland American & Lincoln M. Co.'s plants in Arizona; sampling machinery, screens, etc., for the Holmes Sampling Works in Colorado; concentrating machinery, consisting of four Simplex Bartlett concentrating tables, impact screens, etc., for James Richardson & Sons, Ontario, Canada; experimental concentrating plant for the Imperial Copper Co. in Arizona; machinery and supplies for the Guanajuato Reduction & Mines Co., Ltd., in Old Mexico.

THE Denver Engineering Works Co., McPhee Bldg., Denver, Colo., has developed an electrical drill for stopping and upper workings. This drill is known as the "Box Kid." It follows in design the principles in the Standard box electric rock drill. As in the larger drill, the electric motor is direct connected and when in operation forms part of the drill. The motor is dismounted by the removal of one pin. The motor reciprocates a hollow cylinder carrying the hammer, and the steel is held loosely in the chuck and rotated, the effect being the same as in hand drilling. The complete weight of the drill is 140 pounds. The length of the drill and guide shell, over all, is 28 inches; with feed all out, 43 inches. The length of the feed is 18 inches. Actual running tests show that about 0.75 H. P. is required while drilling at maximum speed. It is claimed that a 1-inch hole can be drilled in Platte canyon granite at the rate of 3 inches per minute. The motor is series wound for 115 or 230 volts, direct current.

## Latest Market Reports.

SAN FRANCISCO, May 5, 1905.

## METALS.

**SILVER.**—Per oz., Troy: London, 26½d (standard ounce, 925 fine); New York, bar silver, 56½c, refined (1000 fine); San Francisco, 56½c; Mexican dollars, 46c, San Francisco; 44½c, New York.

**COPPER.**—New York: Standard, \$15.25; Lake, 1 to 3 casks, \$15@15.25; Electrolytic, 1 to 3 casks, \$15.25; Casting, 1 to 3 casks, \$14.75. San Francisco: \$16.00. Mill copper plates, \$17.00; bars, 18@24c. London: \$65 10s spot per ton.

**LEAD.**—New York, \$4.60; Salt Lake City, \$3.50; St. Louis, \$4.12½; San Francisco, \$3.70, carload lots; 4½c 1000 to 4000 lbs.; pipe 6½c, sheet 7, bar 5½c; pig, \$4.85. London: £12 11s 3d per long ton.

**SPELTZ.**—New York, \$5.80; St. Louis, \$6.15; London, £23 12s 6d per ton; San Francisco, ton lots, 6½c; 100-lb lots, 7c.

**TIN.**—New York, pig, \$30.00@30.30; San Francisco, ton lots, 31½c; 500 lbs., 32c; 200 lbs., 32½c; less, 33½c; bar tin, 3½c. London, £138 5s.

**PLATINUM.**—San Francisco, crude, \$18.50 per oz.; New York, ingot, \$19.50 per Troy oz. Platinum ware, 75@82c per gram.

**QUICKSILVER.**—New York, \$38.00@38.00, large lots; London, £7 7s 6d; San Francisco, local, \$37.00@37.50 per flask of 75 lbs.; Denver, \$45.00.

**BABBITT METAL.**—San Francisco, No. 1, 10c; No. 2, 7c; No. 3, 6½c; extra, 17½c; genuine, 31½c; Eclipse, 35c. Solder.—Half-and-half, 100-lb. lots, 20.50c; San Francisco, Plumbers', 100-lb. lots, 17.25c.

**ZINC.**—Metallic, chemically pure, 3½c; dust, 3½c, 10c; sulphate, 3½c, .04c.

**NICKEL.**—New York, 55@60c per lb.; ton lots, 40@47c. ALUMINUM.—New York, No. 1, 99% pure ingots, 35c; No. 2, 90%, 31@34c.

**ALUMINUM.**—No. 1, 99%, small lots, 37c per lb.; 100 lbs., 35c; 1000 lbs., 34c; ton lots and over, 33c, Pittsburgh. No. 2, 90%, small lots, 34c; ton lots and over, 31c, Pittsburgh.

## STRUCTURAL MATERIALS.

**IRON.**—Pittsburg, Bessemer pig, \$16.35@16.85; gray forge, \$16.65; San Francisco, bar, 3c per lb., 3½c in small quantities.

**STEEL.**—Bessemer billets, Pittsburgh, \$23.00@27.00; open hearth billets, \$23.00@27.00; San Francisco, bar, 7c to 12c per lb.

**WHITE LEAD.**—Per lb., in kegs: 500 lbs. and over at one purchase, per lb., 6½c; less than 500 lbs., per lb., 7c; in 25-lb. tin pails, 4c per lb. above keg price; in 1 and 5-lb. tin cans, 100 lbs. per case, 4c per lb. above keg price. Dry Lead.—In bbls., 1 ton and over, 6½c; do. in kegs, 7c. LIME.—Santa Cruz, \$1.25 country, \$1.25 city per bbl.

**CEMENT.**—Imported, \$2.15@2.65 per bbl.; California, carload lots, \$1.90 f. o. b. at works; small lots, \$2.20 per bbl. in sacks, 4 sacks to bbl., 5c for each sack returned.

**NAILS.**—This week the basic prices are: Wire, \$2.77; Cut, \$3.25. Meanwhile the nominal quotations per keg (list prices) are: No. 20d to 60d, Wire, \$3.35; Cut, \$3.55; 10d to 16d, Wire, \$3.45; Cut, \$3.35; 8d, Wire, \$3.50; Cut, \$3.50; 6d and 7d, Wire, \$3.60; Cut, \$3.60; 4d and 5d, Wire, \$3.70; Cut, \$3.70; 3d, Wire, \$3.85; Cut, \$3.85; 2d, Wire, \$4.10; Cut, \$4.10. Special rates for carload lots.

**LUMBER.**—(Retail): Pine, ordinary sizes, \$24.00@50.00; extra sizes bigger; redwood, \$28.00@30.00; latb, 4 feet, \$4.50@5.00; pickets, \$21.00@shingles, \$2.50 for No. 1, and \$2.25 for No. 2; sbakes, \$13.50 for split and \$15.00 for sawed; rustic, \$28.00@35.00.

## GENERAL SUPPLIES.

**ANTIMONY.**—New York, Cookson's, 7½c; Hallett's, 7½c; San Francisco, 1000-lb. lots, 9c; 300@500-lb. 9½c; 100-lb. lots, 10½c.

**COAL.**—San Francisco, coast, yard prices: Wellington, \$8.00; Seattle, \$6.50; Coos Bay, \$5.50; Southfield, \$8.00. Cargo lot, Eastern and foreign: Wallsend, \$7.50; Brymbo, \$7.50; Pennsylvania, hd., \$14.00; Scotch, \$8.00; Cumberland, \$13.00; Cannel, \$8.50; Welsh Anthracite, \$13.00; Rock Springs, \$8.50, long ton; Colorado Anthracite, \$14.00. Coke, \$10.50 per ton in bulk, \$13.00 in sacks; Sunnyside, \$8.50, long ton.

**POWDER.**—F. o. b. San Francisco: No. 1, 70% nitroglycerine, per lb., in carload lots, 15½c; less than one ton, 17½c. No. 1\*, 60%, carload lots, 13½c; less than one ton, 15½c. No. 1\*\*, 50%, carload lots, 11½c; less than one ton, 13½c. No. 2, 40%, carload lots, 10c; less than one ton, 12c. No. 2, 35%, carload lots, 9½c; less than one ton, 11½c. No. 2\*\*, 30%, carload lots, 9c; less than one ton, 11c. Black blasting powder in carload lots, minimum car 728 kegs, \$1.50 per keg; less car lots, \$2.00 per keg. CAPS.—3x, \$5.50@6 per 1000; 4x, \$6.50@7; 5x, \$8@8.50; Lion, \$9@9.50, in lots not less than 1000.

**FUSE.**—Triple tape, \$4.00 per 1000 feet; double tape, \$3.50; single tape, \$3.10; Hemp, \$2.75; Cement No. 2, \$3.00; Cement No. 1, \$2.65, in lots of 3000 and up.

**CANDLES.**—Granite 6s, 16 oz., 40s., 11c per set; 14 oz., 40s., 9½c.

**CHEMICALS.**—Cyanide of potassium, 98%-99%, jobbing, 23@24c per lb.; carloads, 23@23½c; in tins, 30c; soda ash, \$2.00 per 100 lbs.; hyposulphite of soda, 3@3½c per lb.; caustic soda, in drums, 3@3½c per lb.; Cal. s. soda, bbls., \$1.10@1.20 per 100 lbs.; sks., 90c@1.00; chlorate of potash, 12@13c; nitrate of potash, 6½@7c; caustic potash, 10c in 40-lb. tins; roll sulphur, 2½@2½c; powdered sulphur, 2½@2½c; flour sulphur, French, 2½c—c; alum, \$2.00@2.25; California refined, 1½@2c; sulphide of iron, 8c per lb.; copper sulphate, 5½@5½c; chloride of lime, spot, \$2.50@2.75; sulphuric acid, in carboys, 66% B, 1½@2c per lb.; nitric acid, carboys, 8c per lb.

**BORAX.**—Concentrated, 6@7c per lb.; powdered, 8@10c; fused, 20@25c; crystal, 7c; calcined, 25c.

**BONE ASH.**—Extra No. 1, 5@6c per lb.; No. 1, 4@5c.

**LITHARGE.**—Pure, in 25-lb. bags, 8@9c per lb.

**MOLYBDENUM.**—Best, \$2.75 per lb.

**CHROMIUM.**—90% and over, 3½c per lb., 80c.

**PHOSPHORUS.**—American, 3½c per lb., 70c.

**SODIUM.**—Metal, 3½c per lb., 50c.

**BISMUTH.**—Subnitrate, 3½c per lb., \$2.10.

**URANIUM.**—Oxide, 3½c per lb., \$3.50.

**MERCURY.**—Bicarbonate, 3½c per lb., 7c.

**TUNGSTEN.**—Best, 3½c per lb., \$1.25.

**SILVER.**—Chloride, 3½c per oz., 90c@1.00; nitrate, 55c.

**RED LEAD.**—500 lbs. and over at one purchase, 3½c per lb.; less than 500 lbs., 7½c.

**MANGANESE.**—Black oxide, 3½c per lb., 2½@4c.

**MAGNESIUM.**—Pure, N. Y., \$1.60.

**FIRE BRICK.**—Domestic, carloads 7 1000, f. o. b., factory square, \$25.00; soap and split, \$22.50; arch and wedge, \$27.50; skewback, \$30.00; circle, \$32.00.

**FIRE CLAY.**—Domestic, 3½c per ton 2000 lbs. in 125-lb. bags, double, and dry ground, f. o. b., factory, \$8.50.

## New Patents.

DEWEY, STRONG & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 330 Market street, San Francisco, has official reports of the following United States patents issued to Pacific Coast Inventors:

FOR THE WEEK ENDING APRIL 25, 1905.

788,449.—HOIST—Boquet & Sweeney, Pasadena, Cal.  
788,243.—LOC SAWING MACHINE—C. E. Brown, Dayton, Or.  
788,092.—LEATHER WORK—E. E. Burton, Santa Barbara, Cal.  
788,021.—PHOTO PRINT MACHINE—S. Cohen, Santa Barbara, Cal.  
788,095.—DUMPING CAR—A. W. Dahmer, Sonoma, Cal.  
787,979.—WATER MOTOR—L. D. Falconer, Seattle, Wash.  
788,042.—SWEEPING COMPOUND—A. Ceta, San Francisco.  
788,463.—SHEAVE—J. E. Gilchrist, South Bend, Wash.  
788,464.—GRIP DEVICE—B. H. Green, Los Angeles, Cal.  
787,981.—DENTAL DISK SHIELD—W. F. Green, Modesto, Cal.  
788,185.—SLIP LOOP—C. Heilrath, Sacramento, Cal.  
788,410.—CONCRETE CASING—F. A. Koeltz, San Francisco.  
788,054.—LOOP BOX—W. C. Lawrence, Portland, Or.  
788,485.—VOTING MACHINE—J. B. Mahana, Tacoma, Wash.  
787,992.—RECEIVING DOG—A. B. McCulloch, Kapousin, Wash.  
788,115.—BROILER—C. C. Messmer, Spokane, Wash.  
787,932.—AIR BRAKE—A. D. Miller, Seattle, Wash.  
788,163.—POULTRY COOP—W. Mitchell, North Yakima, Wash.  
787,989.—MUSIC LEAF TURNER—W. J. Morris, Marysville, Wash.  
788,053.—NUT LOCK—W. L. Morrow, Stockton, Cal.  
788,324.—NUT LOCK—W. L. Morrow, Stockton, Cal.  
788,115.—BOTTLE—F. A. Muller, Oakland, Cal.  
788,327.—SAVINGS BOX—A. Nelson, San Francisco.  
788,490.—SWACE—C. L. Nel, Seattle, Wash.  
787,942.—PAVING BLOCK—T. S. Pierce, Walla Walla, Wash.  
787,943.—GATE—L. G. Price, Kings Valley, Or.  
788,067.—VAPOR BURNER—L. Rhodes, Spokane, Wash.  
788,063.—STEAM BOILER—L. Rhodes, Spokane, Wash.  
788,495.—JAR CLOSURE—L. C. Savin, Fullerton, Cal.  
788,075.—MOLE TRAP—A. Y. Swope, Winlock, Wash.  
787,958.—FEED WATER HEATER—Tabrett & Lewin, San Francisco.  
788,289.—CORSET SHIELD—J. S. Thayer, Los Angeles, Cal.  
788,383.—WRENCH—P. C. Thayer, Oroville, Cal.  
788,079.—GAS REGULATOR—F. Wheeler, Los Angeles, Cal.  
788,081.—PLATING MACHINE—W. Wolkan, Portland, Or.

## Notices of Recent Patents.

Among the patents recently obtained through Dewey, Strong & Co.'s SCIENTIFIC PRESS United States and Foreign Patent Agency, the following are worthy of special mention:

**RIBBON PAPER FEEDER AND CUTTER.**—No. 787,662. April 18, 1905. Edwin D. Casterline, San Francisco, Cal. This invention relates to improvements in devices for cutting strips of paper and other material into definite uniform lengths. It is designed especially for cutting cigarette paper and to be used in conjunction with a folding machine. Its object is to provide a simple, durable, automatic, rapid and continuous machine for cutting any number of simultaneously fed paper strips or ribbons into proper uniform lengths. It consists in the combination of two co-operating endless carriers, having each a plane arranged parallel to a plane of the other means, including adjustable longitudinal guides, for varying the space between said planes, other guides carried by the first-named guides and bringing said interspace, a transversely operating cutting device associated with the carriers and means for operating the cutting device and carriers co-ordinately.

**NON-REFILLABLE BOTTLE.**—No. 788,115. April 25, 1905. Frederick A. Muller, Oakland, Cal. This invention relates to a device which is designed to prevent the refilling of bottles after their contents have once been exhausted. It consists in a bottle having a seat at the junction of the neck and body, a valve closable upon the seat, a superposed plug composed of parallel disks with openings which do not register and intermediate shanks of smaller diameter, a second plug located above that first named and having a tortuous passage therethrough and devices by which said plugs are permanently fixed in the bottle-neck.

**CONCRETE CASINGS.**—No. 788,410. April 25, 1905. Frederick A. Koeltz, San Francisco, Cal. This invention relates to a concrete casing which is especially designed for the inclosure of piles and like structures and those parts which are exposed to the ravages of insects or by other deterioration. The device comprises a hollow concrete casing composed of independent lengths axially in line, sleeves by which said sections are maintained in position, an interior pile driven through the casing, an intermediate filling of concrete tamped around the pile and anchor-bolts projecting upwardly from the concrete for the attachment of a cap.

Corrugated Tanks  
For Cyanide Purposes.

For cyanide purposes the corrugated tanks are much superior to plain tanks, for two reasons:

1. The corrugations act as baffles and throw the solution into the sand, thereby assisting the cyanide in percolating the ores instead of running up and down the sides, as is the case with plain tanks.

2. A corrugated tank has in it 10% more material and being arched three ways makes it 6½ times stronger than ordinary tanks.

## Shannon Copper Co.'s Works, Metcalf, Ariz.

In the Clifton district, Graham county, Ariz., one of the important properties is that of the Shannon Copper Company, whose large reduction works are here illustrated. The mines are near Metcalf and 7 miles from Clifton. The company owns a number of mining claims, the most important, however, being the original purchase, the Shannon and Hughes mines. The company built a complete smelting plant on the hillside above the Fresno river, near Clifton; but after a short run the management found that their ore could be more profitably treated if it were first concentrated. Accordingly a concentrator was built on the hill above the smelter. It is fully equipped with the usual rock-crushing devices—breakers, rolls, etc., with trommels, jigs, vanning machines and tables—so that a saving is made all along the line from every grade of material coming from the rolls—coarse, fine and middlings. The oversize from the first trommels goes to the rolls, the oversize from the remaining three trommels going to the jigs. The various sizes of material passing the graded screens of the trommels go to jigs suited to their kind. The jigs tailings are reground in a Huntington mill, the product from which is sent to twelve tables. Other tables treat the overflow from the classifiers. The slimes are run to a division settling tank, from which the clear water is pumped back for reuse. The ores consist principally of pyrite and chalcopryite and chalcocite (copper glance). These sulphides constitute by weight about 20% of the ore, and five tons are concentrated into one. The smelting operations are conducted in the usual manner, the product being matte, which is resmelted and converted at the larger plant of the Arizona Copper Co. The ore is sent from the mine to the railroad by an inclined tramway 1500 feet long, having a vertical rise of 800 feet. The ore is handled in ten-ton cars, the loaded car hauling the empty up. In places the

Pewabic Mine, Gilpin Co., Colo.

ore body is over 300 feet wide. The stopes are timbered by square set method, but little filling is used owing to the good-standing dry ground. There is a great variety of copper ore in the Shannon mine, all being the secondary products of the alteration of chalcopryite. The vein or mineral zone is capped with a heavy deposit of iron oxide, also the result of the decomposition of the sulphide zone, but from which the copper has been leached to a great extent.

## A Central City, Colorado, Mine.

The Pewabic Con. G. M. Co., J. C. Fleschutz manager, has the main shaft down 460 feet on the incline. Levels are driven in two directions at 200, 300 and 400 feet. The 200-foot level is connected by an

upraise with another 200-foot shaft on the Pewabic, to the west of the main working. In the other direction the level has been driven to connect with the 200 foot level of the shaft on the East Pewabic. The East Pewabic is down to a depth of 400 feet, and, with the connections, furnishes air to the other workings. The Lyons and Pewabic veins are 125 feet apart, and it is the intention of the management to install an air compressor, hoist and other machinery on the Lyons and operate it under the same roof as the Pewabic. The illustration on page 299 is that of the interior of the Main Pewabic shaft buildings, showing skip ready to dump. The skip is dumped automatically. The main buildings of this plant are shown in the accompanying illustration. It is one of the important mines of Gilpin county, Colo., and is situated in Russell Gulch, near Central City.

THE law recently passed by the Oregon Legislature in regard to dynamite and other nitro powders, fuse, etc., is calculated to lessen the danger to miners who may be unfamiliar with the physical signs which indicate to the experienced and observing the unfitness of these materials for mining use. Much powder used in mines is old and has been subjected to a wide range of temperature which often unfits it for the best results in mining, beside making it dangerous to handle. The law requires that all powder, fuse, etc., used in blasting operations, either shipped into Oregon or made in that State, shall have the date of manufacture stamped on the box and wrappers containing these articles.

THE latest and not the least interesting phase in the wave of lawsuits sweeping over the smelting industry in the United States is the issue of an order from the United States Circuit Court of Montana directing the Anaconda Copper Co., whose great plant is the Washoe smelter at Anaconda, Mont., to show cause why a temporary injunction should not be issued against the operation of the Washoe smelter. The order has been made on complaint of farmers of the Deer Lodge valley, who claim that their farms and stock have been damaged to the amount of \$2,000,000. This suit has probably been brought in view of the result of the suit of the Government against the Mountain Copper Co. at Keswick, Cal. The order merely calls upon the Anaconda Co. to show cause why their metallurgical operations should not be restrained. What the outcome will be is difficult at this time to state.

THE late agitation over the commercial conditions controlling the production of crude petroleum in the State of Kansas has led to legislation calculated to harmonize conflicting interests and to promote the welfare of the petroleum industry in that State. Among the things accomplished in aid of the oil producers was the passage of bills authorizing the

establishment of an oil refinery to be operated by convict labor; one making pipe lines within the State common carriers, thus placing them on the same footing as railroads; another bill fixing maximum rates of transportation of oil by railroad or pipe line, and these charges for given distances not to be exceeded by any common carrier, the pipe lines being placed under the jurisdiction of the State Railroad Commissioners. Still another law was passed prohibiting discrimination between different localities in that State in the selling of commodities. Whether other oil-producing States will follow the example of Kansas in the effort to promote the oil industry and to prevent discrimination remains to be seen.

## The Locator and His Discovery.

Notwithstanding the fact that the Federal law plainly says a discovery of mineral-bearing rock in place must be made prior to location, many locations are made before a discovery and the actual discovery accomplished later by the work of exploration. The courts have decided that a location so made is valid and dates from the discovery of mineral by the original locator, provided no other party makes a discovery before him. There is, however, a growing tendency on the part of the courts to protect the prospector who locates in good faith and with diligence seeks to make a discovery by working on his claim after the act of location. In those instances where veins plainly outcrop there is no excuse for location prior to discovery; but there are places where discovery is impossible without days, or weeks, and, in some instances, months, of work. Leadville, Colo., affords an excellent example of this condition, for the ore deposits of that district are to a very great extent covered by deep deposits of glacial drift and sheets of porphyry. The siliceous ore bodies of the Cambrian and Carboniferous formations in Lawrence county, S. D., are in many instances similar where the formations originally overlying the ore bodies have not been removed by erosion. In California miles of vein-bearing territory are covered by the debris of the ancient rivers and their volcanic capping. At Tonopah, Nev., the extensions of the known mineral veins run underneath the later andesites, and surface discovery is impossible. It must not be thought that the courts will protect those who merely make locations without discovery, and then make no attempt to find mineral. It requires earnest and continuous effort on the part of the prospector to find a mineral deposit within the lines of his claim by actually working at shaft sinking or tunneling or sinking bore holes. Having found the mineral, an amended location may be made which does not conflict with the pre-existing rights of others. In former years the strict letter of the law was adhered to, and half a dozen different parties might prospect on a given area, all having made locations, and the first party to reach a mineral vein or deposit was awarded the claim by the courts. Leadville furnished numerous examples of this practice; but this was so manifestly unfair to the others whose efforts, while bona fide, had been in vain, that the courts now look with favor upon the first locator who actually shows his good faith by diligent work—not merely the assessment work, but continuous and vigorous work performed daily until a discovery of a vein or ore deposit has actually been made. The conditions here described are preeminently exemplified in the oil regions, where a discovery of oil is practically impossible in most instances without boring a hole from the surface to the oil-bearing stratum, and the courts have protected the first locators who showed substantial evidence of good faith. The Mexican mining laws, framed to advance the mining industry and to promote the exploration of its mineral resources, are far ahead of those of the United States in this regard. There a citizen or resident may apply for exclusive permission to prospect a stated tract of land, and, if there be no legal reason why such permit should not be granted, the mining agent of the district surveys the tract selected and issues the desired permit to prospect and explore for minerals therein for a stated time. Having found mineral, the prospector may then denounce as many pertenencias as he desires to pay the tax upon. The advantage of the Mexican law is in the exclusive privilege which it gives to those who desire to comply with its stipulations.

## Dredger Tailings.

The controversy over the unsightly and useless piles of cobbles left in the wake of many dredgers, which has been going on for some time past, is likely to end in a more careful distribution of the tailings, so that the land, after dredging, may again be tilled with as good results as before. A dredger, the Champlin, operating on Foothills creek, in Jackson county, Or., is overcoming this vexing and somewhat sentimental problem by employing a distributing device, which leaves the tailings in the wake of the dredger smooth and almost in tillable condition. This is accomplished by means of a pump. Instead of discharging the coarse material astern and the fine over the side of the boat, thus leaving the land a succession of mud flats, dotted with ridges and heaps of cobbles, the Champlin dredger discharges all of the material together, as it is mined, leaving the land nearly as level as before.

The level distribution of tailings in the wake of a dredger is not a new idea by any means. Indeed, it was the only way in which it was accomplished at first. There are numerous dredgers working in other States where the tailings are left practically as level as the ground was before, and in some instances it has resulted in leveling the previously existing inequalities of ground which was rolling. These machines employ what is known as the extended adjustable sluice, which carries by far the larger percentage of material raised by the dredging buckets some distance astern of the dredging boat, discharging coarse and fine together 200 feet or more from the face of the bank being torn down by the buckets. The tailings stacker by means of which the ridges and heaps of cobbles are piled up is distinctly a California invention, and all California dredgers are thus equipped, though originally some of the large dredgers in that State had the extended sluices. Among the noted dredgers which leave a comparatively level plane of tailings in their wake are the A. F. Graeter, Graves, Cope, Maggie Gibson and Col. Gordon at Bannock, Mont.; the Conrey Placer Co. No. 2 at Ruby, Mont.; the Pacific Dredging Co.'s dredger at McNutt, Idaho; the Oro Dredging Co.'s boat at Elizabethtown, N. M.; the Atlin No. 1 at Atlin, B. C., and the above mentioned Champlin.

There would be a small gain in the possession of a salable tract of arable land after dredging, whereas by the present California method the land will remain practically useless for some years. Any effort to evenly distribute the dredger tailings must be made at a very low cost, and it must always be accomplished at no greater expense than that of handling the tailings by present methods, for the reason that the value of the land after dredging would bear a very small relation to the amount of gold being recovered. An acre of dredging land having an average depth of 31 feet contains nearly 50,000 cubic yards of gravel. If this land were salable after dredging at \$120 per acre, the ratio of expense which this amount of gravel would bear per cubic yard over the usual method of distributing the tailings would be but \$0.0024—a sum too small to entitle it to grave consideration when mining is carried on for profit.

THE demand for American mining, metallurgical, electrical and mechanical engineers for responsible positions in foreign countries continues. Not a week passes but American engineers leave for distant parts of the earth to assume control or to assist in the development of some new enterprise or to properly adjust an old one. It has long since been learned that the American engineer is not only capable under favorable circumstances, but he is versatile and equal to almost any emergency, and when conveniences do not exist he makes them on the spot—in other words, he can adapt himself to almost any situation, and what he lacks in natural resources of the country he improvises, or substitutes something as good or better than the usual practice.

RECENT concessions as to the levy of taxes on mining property, the cost of concessions, and other matters affecting mining operations in Mexico, are greatly appreciated by American and other foreign investors, and already the beneficent effect of this modification of the law is noticeable in the increased inquiry for mine investment in Mexico.

## CONCENTRATES.

ONLY rich mines can stand the disadvantage of bad management, and there are many such mines.

A PATENT to extract gold, silver and copper from ores by the ammonia cyanide process was issued to J. W. Simpson in July, 1885—patent No. 323,222.

THE best and most enduring "U" bolts for machine drills are made of cold rolled steel. This material is also the best for making rocker pins for machines.

THERE is a diversity of opinion as to the relative merits of wet or dry crushing of ores. With some ores wet crushing undoubtedly gives better results than with dry and vice versa.

IN all cases where the ore is amenable to amalgamation undoubtedly the best process is stamp milling with the usual practice adapted to the particular conditions, or the ore, locality, etc.

IN many cases where the ordinary "cross-bit" of a machine drill becomes fitchered and no further progress can be made without much loss of time, a chisel bit will often finish the hole without more trouble.

LEAD-SILVER BULLION is refined by electrolysis under patented processes, and is usually practiced in those districts from which it does not pay to ship out the lead. Such localities are rare, however.

IN Mexico a mine operator may drain his mine in any manner he may choose to adopt, but he is responsible for any damage or loss that may be occasioned in other neighboring mines from not properly draining his own property.

LITHOLOGY treats of rocks as mineral masses, and petrography is the science of the structure and chemical composition of rocks and of their individual minerals. The study is generally carried on with the aid of the microscope.

INVESTIGATION of fuels by the United States Geological Survey has shown that a ton of bituminous coal is capable of producing two and a half times as many heat units when producer gas is made from the coal as when it is burned in the usual way in the fire box of a boiler.

AIR COMPRESSORS are often provided with automatic governors, which regulate the operation of the machine, keeping the air pressure within certain limits as determined by the arrangement of the governor. The allowable variation in pressure generally ranges from 5 to 10 pounds per square inch.

GRANULAR pyrite often occurs in veins of high-grade ore, and is found to be practically valueless, the pyrite acting the same as gangue. This condition is found in numerous Colorado and Arizona mines. With the addition of zinc, lead or copper sulphides to the pyrite, gold and silver values generally appear also.

BY short circuit is meant a direct connection by accident or design of the positive and negative leads of a supply circuit or dynamo by a conductor of low resistance. This allows an excessive current to flow, which, owing to the heat produced, will fuse the leads and possibly overload the generator supplying the current and thus destroy its insulation.

WHERE a claim owner has applied for patent, but at the time the money should be paid into the land office he decides not to make payment, the patent will not issue, but the claim owner does not lose his possessory title to the claim by reason of such failure, as he can continue to hold it as long as he complies with the laws governing unpatented claims.

THE radiation from a furnace, of whatever type, is almost a constant quantity, no matter whether the walls be thick or thin nor whatever the material of their construction may be. Recent experiment has determined that reverberatory furnaces having thin walls—9 inches or thereabouts—lose no more heat by radiation than those having walls 24 to 30 inches in thickness.

WHERE ten stamps, of 1000 pounds weight each, are attached to one shaft, this shaft should be at least 6 inches diameter, and, if the stamps weigh more than 1000 pounds, the cam shaft should be increased in diameter to 6½ inches or more. Hammered high-grade iron is considered the best material from which to make cam shafts, although steel is generally used for this purpose.
